## Intellectual Property

For a list of trademarks and patents that are owned by Flexera Software, see <https://www.revenera.com/legal/intellectual-property.html>. All other brand and product names mentioned in Flexera Software products, product documentation, and marketing materials are the trademarks and registered trademarks of their respective owners.

## Restricted Rights Legend

The Software is commercial computer software. If the user or licensee of the Software is an agency, department, or other entity of the United States Government, the use, duplication, reproduction, release, modification, disclosure, or transfer of the Software, or any related documentation of any kind, including technical data and manuals, is restricted by a license agreement or by the terms of this Agreement in accordance with Federal Acquisition Regulation 12.212 for civilian purposes and Defense Federal Acquisition Regulation Supplement 227.7202 for military purposes. The Software was developed fully at private expense. All other use is prohibited.

| BatchGetFileName Example .....             | 571 |
| BatchMoveEx .....                          | 572 |
| BatchMoveEx Example .....                  | 574 |
| BatchSetFileName .....                     | 575 |
| BatchSetFileName Example .....             | 576 |
| CalculateAndAddFileCost .....              | 577 |
| CallDLLFx .....                            | 578 |
| CallDLLFx Example .....                    | 579 |
| ChangeDirectory .....                      | 580 |
| ChangeDirectory Example .....              | 581 |
| CharReplace .....                          | 582 |
| CharReplace Example .....                  | 583 |
| CloseFile .....                            | 584 |
| CloseFile Example .....                    | 585 |
| CmdGetHwndDlg .....                        | 586 |
| CmdGetHwndDlg Example .....                | 587 |
| CoCreateObject .....                       | 589 |
| CoCreateObjectDotNet .....                 | 590 |
| CoGetObject .....                          | 590 |
| CoGetObject Example .....                  | 591 |
| ConfigAdd .....                            | 592 |
| ConfigAdd Example .....                    | 594 |
| ConfigDelete .....                         | 595 |
| ConfigDelete Example .....                 | 596 |
| ConfigFileLoad .....                       | 597 |
| ConfigFileLoad Example .....               | 598 |
| ConfigFileSave .....                       | 600 |
| ConfigFileSave Example .....               | 601 |
| ConfigFind .....                           | 603 |
| ConfigFind Example .....                   | 605 |
| ConfigGetFileName .....                    | 606 |
| ConfigGetFileName Example .....            | 607 |
| ConfigGetInt .....                         | 608 |
| ConfigGetInt Example .....                 | 609 |
| ConfigMove .....                           | 611 |
| ConfigMove Example .....                   | 612 |
| ConfigSetFileName .....                    | 614 |
| ConfigSetFileName Example .....            | 615 |
| ConfigSetInt .....                         | 616 |
| ConfigSetInt Example .....                 | 617 |
| ConvertSizeToUnits .....                   | 619 |
| ConvertWinHighLowSizeToISHighLowSize ..... | 621 |
| CopyBytes .....                            | 622 |
| CopyBytes Example .....                    | 623 |
| CopyCHARArrayToIStringArray .....          | 624 |

# InstallScript Language Reference

InstallShield makes designing your installation easy with InstallScript, a simple but powerful programming language. InstallScript is similar to the C language. It has a defined format and regulated syntax. It uses certain data types, each with specific properties. It also allows you to create custom functions.

InstallScript, however, does not provide the full range of programming functionality that C does. InstallScript was designed to do one thing—create installations. And it does so better than any programming language in the world. Regardless of your programming background, you can quickly learn to build an installation with InstallScript.

**Project** ▪ Some InstallScript functions, events, and variables are limited to specific project types.

**Table -1** ▪ InstallScript Language Reference

| Section                      | Description                                                                                                                                                                                                                               |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Integrated Compiler</b>   | Provides general information about the InstallScript integrated compiler.                                                                                                                                                                 |
| <b>Command-Line Compiler</b> | Contains details about the InstallScript command-line compiler that can be invoked from the DOS prompt or from a DOS batch file.                                                                                                          |
| <b>Setup Scripts</b>         | Introduces you to the InstallScript language and the structure of a script.                                                                                                                                                               |
| <b>Language Keywords</b>     | Presents background about language keywords, which are words InstallScript uses as commands in the script. Language keywords are interpreted by the InstallScript compiler to perform some action, or are considered part of a statement. |
| <b>Predefined Constants</b>  | Identifies and describes each of the predefined constants reserved by InstallScript. These constants represent specific literal values that are passed to and returned by built-in functions.                                             |

**Table -1** ■ InstallScript Language Reference (cont.)

| Section                                     | Description                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Predefined Script Variables</b>          | Contains information about script variables that you can use with InstallScript.                                                                                                                                                                                                                                                                                              |
| <b>Data Types and Predefined Structures</b> | Contains content about the data types and predefined structures supported in InstallScript.                                                                                                                                                                                                                                                                                   |
| <b>Preprocessor Directives</b>              | Discusses preprocessor directives, which are instructions to the InstallScript compiler that are executed as the script is compiled. Preprocessor directives can instruct the compiler to include other source files in the compilation, to define constants, to include or exclude statements based on compile-time conditions, and to display a user-defined error message. |
| <b>Flow Control</b>                         | Contains information on how to control the flow of execution within scripts.                                                                                                                                                                                                                                                                                                  |
| <b>Event Handlers</b>                       | InstallScript project installation programs are driven by the InstallScript engine, which generates a series of events in a specific order.                                                                                                                                                                                                                                   |
| <b>Functions</b>                            | Describes the different types of functions that you can use in your installation scripts; also includes details about—and examples of—each of the built-in functions available in InstallScript.                                                                                                                                                                              |
| <b>Operators</b>                            | Contains information about supported operators in InstallScript.                                                                                                                                                                                                                                                                                                              |
| <b>Objects and Object Handlers</b>          | Contains information about the objects that InstallScript supports and how to separate error handling from the rest of your script code.                                                                                                                                                                                                                                      |

**Note** ■ Some of the functions that were available in InstallShield Professional are deprecated in later versions of InstallShield. To view a list of the functions, see *Unsupported Functions*.

Because the InstallShield Help Library is designed to interact with InstallShield, it is recommended that you open the help from within InstallShield. Copying the help files to another folder or system causes many of its features to work incorrectly.

## Integrated Compiler

If you want to compile your script without building a release, you can use the integrated InstallScript compiler in InstallShield.

**Task****To compile your script:**

On the **Build** menu, click **Compile**.

InstallShield displays compiler messages in the Output window.

## Command-Line Compiler

In addition to the integrated compiler, which you can launch from within InstallShield, InstallShield includes a command-line compiler that you can invoke from the DOS prompt or from a DOS batch file. This program, called `Compile.exe`, is in the following folder:

*InstallShield Program Files Folder/System*

After you have completed the design of an installation project, you can use `Compile.exe` to compile the installation script using different options than those that are used when you compile the script from within InstallShield.

For the syntax and available command-line parameters and switches for `Compile.exe`, see `Compile.exe`.

**Note** ▪ When you build a release from the command line using `ISCmdBld.exe`, the build engine automatically compiles your script; therefore, you do not need to use `Compile.exe` directly unless you want to use compiler options that are different from those specified for the project in InstallShield. For more information, see `ISCmdBld.exe`.

# Setup Scripts

A setup script is a collection of event handlers, functions called by those event handlers, and data used by the event handlers and functions. These elements are expressed in the InstallScript Language, a simple but powerful programming language. InstallScript is similar to the C language. It has a defined format and regulated syntax. It uses certain data types, each with specific properties. It also allows you to create custom functions.

InstallScript, however, does not provide the full range of programming functionality that C does. InstallScript was designed to do one thing—create setups. And it does this effectively and efficiently.

Regardless of your programming background, you can learn quickly to build your setup with InstallScript.

## InstallScript Limits

Following are limits for the compiled script file (setup.inx):

- Maximum number of statements: about 4,294,967,295 (If this limit is exceeded, error -5009 may occur during setup initialization.)
- Maximum number of global variables: about 196,605 (65,535 numbers, 65,535 variants, 65,535 strings)
- Maximum number of typedefs: about 65,535
- Maximum number of prototypes: about 65,535
- Maximum number of functions: about 65,535
- Maximum number of statements per function: about 65,535
- Maximum local variables per function: about 196,605 (65,535 numbers, 65,535 variants, 65,535 strings)

Following are limits for script files (.rul):

- Maximum line width: 1,024 characters
- Maximum number of nested include files: 80
- Maximum number of include files: 2,048
- Maximum identifier length: 63 characters
- Maximum number of macro expansions: 100
- Maximum macro expansion text length: 256 characters
- Maximum file name length: 256 characters
- Maximum number of nested #if statements: 10
- Maximum number of parameters per function: 16

Compile errors occur if one or more of these .rul limits are exceeded.

**Tip** ▪ If you encounter any of the aforementioned limits, consider reducing the size of your installation script by removing code, or by splitting up your installation script into multiple projects, creating separate installations, and calling the child installations from your main installation (parent installation).

## Structure of a Script

Every script includes declarations and function blocks. Declarations can precede function declarations or appear between a function statement and the begin statement for that function.

The general outline of a script is shown below:

```
// Constant definitions, global data declarations, and function declarations

// Function blocks
```

## Declarations

Every script begins with global data declarations. Here, you define constants and declare each of the global variables and user-defined functions that you will be using. Declarations instruct the InstallScript compiler that the script will be using the listed items at a later time. Declarations also build an association between a function and its attributes or values. You do not need to declare any of the built-in functions, since the InstallScript compiler already recognizes the function names.

Below are some examples of constant definitions, data declarations, and function declarations:

```
// Constant definitions
#define PRODUCT "InstallShield"
#define LIMIT    100

// Variable declarations
CHAR  cVal;
NUMBER nVal;
STRING szName;

// Function declarations
prototype DisplayMsg (NUMBER, STRING);
prototype GetName (BYREF STRING);
```

## Program Block

Program blocks are used in scripts written using InstallShield Professional 5.5 or earlier. A program block cannot be used for an InstallScript custom action or in an event-driven script. The only code that is executed is found in event handlers and entry-point functions.

```
program
```

```
// In an event-driven script, the program block is optional and remains empty.
```

```
endprogram
```

## Function Block

---

**Project** ▪ This information applies to InstallScript projects.

All functions that have been declared with a prototype statement must be defined in the function block, which follows the keyword `endprogram` in a setup script. Additional global data declarations may be made in the function block, either between the `endprogram` statement and the first function declaration or between function declarations. However, data declared in the function block is visible only to functions that are defined after the data declaration.

## Identifiers

Identifiers are the names that you create to denote constants, variables, and functions in your script. Observe the following syntax rules when creating identifiers:

- An identifier may be of any length, but only the first 63 characters are significant.
- The first character of an identifier must be alphabetic (a-z, A-Z) or an underscore.
- The remaining characters may be alphabetic (a-z, A-Z), numeric (0-9), or an underscore.
- Each identifier must be unique. Be careful not to create an identifier that is a reserved word in InstallScript.

## Syntax Punctuation Rules

Like any programming language, InstallScript has syntax rules that regulate its usage. The basic syntax of InstallScript is similar to that of the C programming language.

The following punctuation reminders apply to all sections of the script:

- Most statements end with a semicolon (;). This includes many one-word statements, such as `end;`, `exit;`, and `return;`.
- Preprocessor statements—such as `#define` and `#include`—never end with a semicolon.
- The keywords `program`, `endprogram`, and `begin` are placed on separate lines by themselves and receive no punctuation. The function line that begins each function block receives no punctuation.
- End a label, such as `start:` or `starthere:`, with a colon (:).
- Enclose parameter lists within parentheses. Separate multiple parameters with commas.

## Writing Comments

InstallScript gives you two ways to create comments in a script. You can use either method to add explanatory text to your script or to exclude or “comment out” certain parts of your script for testing and debugging purposes.

**Caution** • You can begin comments anywhere in a script—with one exception: Comments cannot be placed on the same line as an `#ifdef` or `#ifndef` statement. You must write comments before or after these statements, if necessary. Otherwise, the compiler returns an error.

### Block of Text

One way to create a comment is to enclose a block of text between the character pairs `/*` and `*/`. This method makes it easy to write a comment over multiple lines:

```
/* This is a line of sample code that shows you
 * how to use the InstallScript function PlaceBitmap. */
```

## Line by Line

The second way is to insert the characters `//` into a line. The compiler ignores everything to the right of the double slashes on that line only.

```
// This is a line of sample code showing the
// InstallScript function PlaceBitmap.
```

# Using White Space

Like C and other programming languages, InstallScript does not recognize white space (spaces and tabs, carriage returns) except in a string literal. It is recommended that you use white space to make your script easier to follow.

## Code Without White Space

For example, the following section of code is dense and difficult to decipher:

```
#define DISK_DRIVE "C:\\\"
    STRING szDrive, svString;
    NUMBER nSpace, nResult;
szDrive = DISK_DRIVE;
nSpace = GetDiskSpace(szDrive);
nResult = NumToStr(svString, nSpace);
if (nResult < 0) then
    MessageBox("NumToStr failed.", SEVERE);
abort;
endif;
sprintfBox(INFORMATION, "Info", "Disk Space: %s", svString);
```

## Code With White Space

Adding white space with indentation makes the same code much easier to read:

```
#define DISK_DRIVE "C:\\\"

    STRING szDrive, svString;
    NUMBER nSpace, nResult;

    szDrive = DISK_DRIVE;
    nSpace = GetDiskSpace(szDrive);

    nResult = NumToStr(svString, nSpace);
    if (nResult < 0) then
        MessageBox("NumToStr failed.", SEVERE);
        abort;
    endif;

    sprintfBox(INFORMATION, "Info",
        "Disk Space: %s", svString);
```

# Hungarian Notation

InstallShield help topics employ an extended form of Hungarian notation—a naming convention that uses short, lowercase prefixes to indicate the data type. For example, `iPointSize` denotes an integer variable, while `szFileName` indicates a string variable.

Hungarian notation is used in example scripts to indicate the data type of all variables. In function syntax descriptions, Hungarian notation is used for parameter names to indicate the type of data that may be passed in a parameter. For example, the syntax description of `BatchDeleteEx` shows that it takes two parameters:

```
BatchDeleteEx ( szKey, nOptions );
```

The first parameter, identified as `szKey`, could be a string variable or constant. The second, identified as `nOptions`, could be a number variable or constant.

## Variable Parameters

In those cases where a variable parameter is required, the Language reference employs a special set of two-letter prefixes:

- The first letter indicates the data type.
- The second character is the letter `v`, for variable.

In the syntax description for `GetDir`, the first parameter can be a string variable or constant, but the second parameter must be a variable.

```
GetDir ( szPath, svDir );
```

Functions that require variable parameters generally return data to the caller in those parameters.

## Prefix Table

Because Hungarian notation makes it easy to recognize a variable's type, it is strongly recommended that you use Hungarian notation when you create variable names in your own scripts. The table below describes each of the prefixes used in InstallShield.

**Table 1** - Prefix Table

| Prefix       | Data Type           | When Used in Function Syntax                               |
|--------------|---------------------|------------------------------------------------------------|
| <b>b</b>     | Boolean (BOOL)      | Boolean constant, literal, or variable.                    |
| <b>bv</b>    | Boolean (BOOL)      | Boolean variable only. Constants and literals not allowed. |
| <b>c</b>     | Character (CHAR)    | Character constant, literal, or variable.                  |
| <b>const</b> | Constant            | Constant or literal. Variables not allowed.                |
| <b>h</b>     | Handle (HWND)       | Handle variable.                                           |
| <b>i</b>     | Integer (INT)       | Integer constant, literal, or variable.                    |
| <b>l</b>     | Long integer (LONG) | Long integer constant, literal, or variable.               |

**Table 1** • Prefix Table (cont.)

| Prefix         | Data Type                           | When Used in Function Syntax                                    |
|----------------|-------------------------------------|-----------------------------------------------------------------|
| <b>lv</b>      | Long integer (LONG)                 | Long integer variable only. Constants and literals not allowed. |
| <b>list</b>    | List (LIST)                         | List variable.                                                  |
| <b>n</b>       | Number (NUMBER)                     | Number constant, literal, or variable.                          |
| <b>nv</b>      | Number (NUMBER)                     | Number variable only. Constants and literals not allowed.       |
| <b>p</b>       | Pointer (POINTER)                   | Pointer variable.                                               |
| <b>pstruct</b> | Pointer to a defined structure type | Not used.                                                       |
| <b>s</b>       | Short integer (SHORT)               | Short integer constant, literal, or variable.                   |
| <b>sz</b>      | String (STRING)                     | String constant, literal, or variable.                          |
| <b>sv</b>      | String (STRING)                     | String variable only. Constants and literals not allowed.       |
| <b>struct</b>  | Defined structure type              | Not used.                                                       |

## Escape Sequences

An escape sequence is a set of characters used to insert into a string certain special characters—such as tabs, carriage returns and quotation marks. Escape sequences in InstallScript are very much like those in C. They begin with a backslash, called an escape character, and the backslash is followed by one or more characters that have special meaning. If the backslash is followed by characters other than those used in an escape sequence, the backslash is ignored.

### Inserting a Newline Character Into a String

A commonly used escape sequence is `\n`, which inserts a newline character into a string. The string “This is line one, This is line two.” is displayed or printed on a single line. However, the string “This is line one,\nThis is line two.” is displayed or printed as shown below:

```
This is line one,
This is line two.
```

**Note** • The `\n` escape sequence works only in multiline static text fields. For example, you can insert `\n` in the `szQuestion` argument of `AskText` to manually format the string. You can also use `\n` with `MessageBox` and `SprintfBox`.

The newline escape sequence is case sensitive; that is, `\N` does not insert a newline character.

The percent sign (%) also has a special function in InstallScript; it is used as the first character of a format specifier, which is a sequence of characters that is used with functions such as *Sprintf* and *SprintBox* to indicate how the value stored in a variable should be displayed on screen.

## Supported Escape Sequences

The following table lists the escape sequences that are supported by InstallScript:

**Table 2 • Supported Escape Sequences**

| Escape Sequence   | Performs the Following Action                                  |
|-------------------|----------------------------------------------------------------|
| <code>\n</code>   | Inserts a line feed.                                           |
| <code>\'</code>   | Inserts a single quotation mark in the string.                 |
| <code>\"</code>   | Inserts a double quotation mark in the string.                 |
| <code>\r</code>   | Inserts a carriage return only. Does not insert a line feed.   |
| <code>\t</code>   | Inserts a tab character.                                       |
| <code>\ooo</code> | Indicates an ASCII character—not an integer—in octal notation. |
| <code>\\</code>   | Inserts a backslash.                                           |

## Specifying a Universal Naming Convention Path

To specify a Universal Naming Convention (UNC) path in an InstallScript string, you must use two backslash escape sequences (that is, four backslashes—\\), to create the double backslash at the start of the path. For example, the path `\\MyServer\Public\Readme.txt` must be specified as follows:

```
"\\\\MyServer\\Public\\Readme.txt"
```

## Embedding Quotation Marks

You can insert double quotation marks as part of a string literal using one of two methods. If you begin the string literal with double quotation marks, you must use the `\"` escape character to embed double quotation marks. You can, however, begin the literal with a single quotation mark and then type the double quotation mark:

```
//These two statements will both yield embedded double quotation marks
szQuote1 = "Who said, \"Quitters never win\"?";
szQuote2 = 'The same guy who said, "I quit. "';
```

To embed a single quotation mark, either use the `\'` escape sequence or open the string literal with double quotation marks:

```
//These two statements will both yield embedded single quotation marks
szQuote1 = 'Who said, \'Nice guys finish last\'?';
szQuote2 = "The same guy who said, 'I win.'";
```

**Note** - Your setup scripts must use the standard quotation marks (" and ') found to the right of the semicolon (;) key on the standard U.S. keyboard. Do not use open or closed typographer's quotation marks (""), such as this help files uses outside of example scripts.

## Format Specifiers

Format specifiers are used with the functions `Sprintf` and `SprintfBox` to control the display of values that are stored in variables. A format specifier begins with a percent sign (%) and is followed by at least one or two characters. Format specifications follow the format shown below:

% [-] [#] [0] [width] [.precision] type

Each field of a format specification is a single character or number that represents a particular format option. The type field, for example, determines whether `Sprintf` or `SprintfBox` interprets the associated argument as a character, a string, or a number. The initial character % and the type field are both required. Items enclosed within brackets are optional. The simplest format specification contains only the percent sign and a type character, for example %s.

In the following example, the value of `svString` is displayed in a message box. The format specifier %s, which is assigned to `svFormat`, indicates to `SprintfBox` that the value of `svString` should be displayed as a string of characters.

```
STRING szTitle, szFormat, szString;

szTitle = "Demonstrate format specifiers";
szFormat = "%s";
szString = "This is a string.";

SprintfBox(INFORMATION, szTitle, szFormat, szString);
```

The value assigned to `svFormat` may contain literal characters (including escape sequences) that are to be displayed along with the value of a variable. In the following example, an identifying label is displayed to the left of a number variable: `nNumber = 100`.

```
STRING szTitle, szFormat;
NUMBER nNumber;

szTitle = "Demonstrate format specifiers";
szFormat = "nNumber = %d.";
nNumber = 100;

SprintfBox(INFORMATION, szTitle, szFormat, nNumber);
```

**Note** - To print a percent sign, you must insert two percent signs in the string assigned to `svFormat`. Assuming that the number to be printed is 100, the following format specification string displays "nNumber = 100%":

```
svFormat = "nNumber = %d%%."
```

**Table 3** • Format Specifier Fields

| Field            | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -                | If you include a hyphen after the percent character, the output value is aligned left and padded on the right to the width of the field with blanks or zeros. If you omit this field, the output value is right aligned and padded on the left.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| #                | Use this symbol to prefix hexadecimal values with 0x (lowercase) or 0X (uppercase).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0                | Pads the output value with zeros to fill the field width. If you omit this field, the output value is padded with blanks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>width</b>     | Enter the minimum number of characters you want to place in this field. Type the width field as a non-negative integer. When you enter a width specification, the value is never truncated. If the number of characters in the output value is greater than the width specified, or if you omit the width field, every character of the value is displayed, subject to the value of the precision field.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>precision</b> | Enter the minimum number of digits you want in this field. If the number of digits in the argument is less than the precision value you enter, the output value on the left is padded with zeros. When the number of digits exceeds the precision value, the value is not truncated. If you enter a precision value of zero or omit it entirely, or if the period (.) appears without a number following it, the precision is set to 1. For strings, convert the maximum number of characters.                                                                                                                                                                                                                                                                                    |
| <b>type</b>      | <p>Format the corresponding argument as a character, a string, or a number. When two format specifier letter combinations are shown, you can use one or the other, but not both at the same time. This is a required field. In this field you must enter one of the following characters:</p> <ul style="list-style-type: none"> <li>● <b>c</b>—Formats a single character of type CHAR. The Sprintf function ignores a character with a numeric value of zero.</li> <li>● <b>d, i</b>—Formats a single integer of type INT or of type NUMBER.</li> <li>● <b>ld, li</b>—Formats a single signed decimal integer of type LONG.</li> <li>● <b>lx, lX</b>—Formats a single unsigned hexadecimal integer of type LONG.</li> <li>● <b>s</b>—Formats a string (type STRING).</li> </ul> |

Each format specifier has a matching variable. The variables are listed from left to right after the string, with the first variable matching the first format specifier in the string, the second variable matching the second format specifier in the string, and so on. At run time, InstallShield inserts each variable's contents into the string at the location of its matching format specifier.

# Reserved Words

Reserved words and characters have special meaning in InstallScript and cannot be used except for their intended purposes. InstallScript has the following classes of reserved words:

- [Functions](#)
- [Language Keywords](#)
- [Predefined Constants](#)
- [System Variables](#)
- [Event Handlers](#)
- [Predefined Script Variables](#)

# Language Keywords

Language keywords are words InstallScript uses as commands in the script. Language keywords are interpreted by the InstallScript compiler to perform some action, or are considered part of a statement. You cannot use these following keywords for any reason other than their predefined purpose (for example, these keywords cannot be used as variable names).

## abort

When the script encounters an abort statement, the setup terminates. The abort statement is also encountered in the InstallShield default exit handler (OnCanceling) when the end user exits the installation before it has completed by pressing the Esc key or the Cancel button of an InstallScript dialog.

**Note** ▪ The abort statement exits the installation and runs the uninstaller in silent mode to clean up the aborted installation. The exit statement aborts the installation, but does not remove anything from the target system.

The abort statement does not call a rollback if initiated after the OnFirstUIAfter event.

## BOOL

Boolean data: either TRUE (1) or FALSE (0). Variables of this type should not be used to store any other values. Like C++, InstallScript evaluates non-zero values as TRUE; only the value of zero is evaluated as FALSE. Normally, the value of 1 is used to indicate TRUE.

## cdecl

**Project** ▪ This information applies to InstallScript projects.

The cdecl keyword is used when declaring an external DLL function that uses the cdecl calling convention. For example:

```
prototype cdecl POINTER Msvcrt.memcpy( byref string, pointer, long );
```

In previous versions of InstallShield Professional, the setup engine always used the **stdcall** convention but would sometimes overlook an inconsistent DLL convention.

Most Windows API functions use the stdcall (WINAPI) calling convention. Consult Microsoft documentation for more information about calling conventions.

## exit

When the setup program encounters an exit statement in the script it is executing, the setup process terminates. Each setup script contains—at most—one exit statement. If your script includes conditional expressions that might cause it to exit before the installation has completed, you should use **abort** instead of exit.

## export

The prototype of any function that is called directly by the setup engine must be marked as export. An example is shown below:

```
export prototype NewFeature1_Installing();
```

## external

The keyword external is reserved and may not be used.

## for...endfor

The for statement is designed to execute one or more statements a fixed number of times. It begins with the keyword for and an expression that specifies the number of times statements within the for structure are to be executed. The for structure ends with the keyword endfor.

**Note** ▪ The for statement itself is not terminated with a semicolon; however, a semicolon is required after the endfor statement.

### Using for...endfor

In the following example, the function MessageBox is called 10 times. On the first pass, iCount is set to 1. Because 1 is in the specified range (1 to 10), the message box is displayed. Then iCount is incremented by 1 and the for statement is resolved again. This time, iCount = 2 (still in the specified range) and the message box is displayed a second time.

When iCount is incremented after the tenth pass, its value becomes 11. Because this value is outside the specified range, the for statement ends.

```
for iCount = 1 to 10
    MessageBox ("This appears ten times.", INFORMATION);
endfor;
```

### Adjusting the Increment

The default increment in a for statement is one (1), but you can use the keyword step to adjust the increment. In the example below, step increases the value of iCount by 10 each time loop is executed. On the first pass, iCount = 10; on the second pass, iCount = 20; on the third pass, iCount = 30, and so on.

```
for iCount = 10 to 100 step 10
    MessageBox ("This appears ten times.", INFORMATION);
endfor;
```

Counting Down from a Higher Number to a Lower Number

You can count down from a higher number to a lower number by using the keyword downto in place of the keyword to. In the following example, a message box is displayed three times. The first time the loop is entered, j is set to 20.

Because `downto` specifies that the controlling variable be decremented and step 5 sets a decrement of 5 per loop, `j` is equal to 15 the second time the loop is entered. The third time, `j` is equal to 10.

```
for j = 20 downto 10 step 5
    MessageBox ("This appears three times.", INFORMATION);
endfor;
```

---

**Note** ▪ You cannot define a label within a `for` statement.

## goto

The `goto` keyword is used to branch directly to the statement immediately following a specified label. In the following code fragment, the `goto` statement causes execution to continue with the `AskText` statement.

```
Name:
AskText("Company name:", "", szSrc);

if (szSrc = "") then
    MessageBox("Please enter the company name.", SEVERE);
    goto Name;
endif;
```

A `goto` statement in the main program must specify a label that has been declared in the main program. A `goto` statement in a function must specify a label that has been declared in that function.

---

**Note** ▪ You cannot use a `goto` statement within a `try...catch...endcatch` statement.

## if

Use an `if` statement when you want your script to choose between two or more options. An `if` statement consists of the keyword `if`, a condition to be evaluated, the keyword `then`, and the keyword `endif` followed by a semicolon, as shown below:

```
if (condition) then
    // statements to be executed if condition is true
endif;
```

The condition can be one of the following:

- A Boolean or integer constant, variable or literal.
- An expression that produces a Boolean or integer result.
- A function that returns an integer result.

The parentheses around the condition are optional, but highly recommended for readability.

---

**Tip** ▪ Many `InstallScript` functions return a negative value when they fail. When using the result of `InstallScript` functions as the condition in an `if` statement, test for failure by using a statement like the one below:

```

if (FunctionA (ParameterOne) < 0) then
    // Statements to handle the failure
else
    // Statements when the function succeeds
endif;

```

InstallScript provides the following if statement structures:

- **if Structure with goto**
- **if-then Structure**
- **if-then-else Structure**
- **Nested if-then-else Structure**
- **elseif Structure**

## if Structure with goto

InstallScript supports a special form of the if statement that can be used only with goto statements:

```

if condition goto labelname;

```

This special structure is has the following features:

- The condition must be followed by a goto statement.
- The keyword then is not used.
- The keyword endif is not used.

In the following example, the user will be prompted to enter a company name as long as szSrc is a null string ("").

```

Name:
AskText("Company name:", "", szSrc);
if (szSrc = "") goto Name;

```

## if-then Structure

The simplest if statement evaluates an expression and performs a specified action if the expression is true. If the expression is not true, InstallShield ignores the entire statement. For example:

```

if (szStringA = "exit") then
    AskYesNo ( "Are you sure you want to exit?", NO );
endif;

```

If szStringA equals "exit", the test evaluates to TRUE (1) and the AskYesNo function is called. If szStringA contains anything else, the result is FALSE (0) and the entire statement is ignored.

The sample code below compares the values of the variable nDialog and the constant DLG\_ERR. If they are equivalent, InstallShield executes the MessageBox function:

```

if (nDialog = DLG_ERR) then
    MessageBox ("Error has occurred", WARNING);
endif;

```

**Tip** • You may find that your if statement is easier to read when you place the expression to be evaluated in parentheses, but the parentheses are optional in InstallScript.

## if-then-else Structure

An if statement can also specify one or more statements to be executed if the condition is false. This option is indicated with the keyword else, as shown below:

```
if (condition) then
    // statements to be executed if condition is true
else
    // statements to be executed if condition is false
endif;
```

In the example below, if szStringA equals "exit," the test evaluates to TRUE (1), and the AskYesNo function is called. If szStringA is not equal to "exit," the result is FALSE (0), and the MessageBox function is called following the else statement.

```
if szStringA = "exit" then
    AskYesNo ("Are you sure you want to exit?", NO );
else
    MessageBox ("Please wait... ", INFORMATION );
endif;
```

## Nested if-then-else Structure

You can create nested if statements, in which one if statement is embedded in another:

```
if (first condition) then
    if (second condition) then
        // statements to be executed if first and
        // second conditions are true
    else
        // statements to be executed if first is true but
        // second condition is false
    endif;
else
    if (third condition) then
        // statements to be executed if first condition is
        // false and third condition is true
    else
        // statements to be executed if first condition is
        // false and third condition is false
    endif;
endif;
```

In the following example, if the value of szStringA is "exit", AskYesNo is called. If the value of szStringA is "exit", the program displays a message box. If szStringA is not equal to either of those values, the execution proceeds to the label UserErrorHandler.

```
if szStringA = "exit" then
    AskYesNo ("Are you sure you want to exit?", NO);
else
```

```

    if szStringA = "continue" then
        MessageBox ("Please wait...", INFORMATION);
    else
        UserErrorHandler;
    endif;
endif;

```

## elseif Structure

InstallScript provides the elseif statement to create if structures in which the else branch of one if statement leads to another if statement:

```

if (first condition) then
    // statements to be executed if first condition
    // is true
elseif (second condition) then
    // statements to be executed if first condition
    // is false and second condition is true
elseif (third condition) then
    // statements to be executed if first and second
    // conditions are false and third condition is
    // true
endif;

```

In the following example, if szStringA equals “exit,” AskYesNo is called. If szStringA is not equal to “exit,” the program continues to the elseif statement to test if szStringA is equal to “continue.” If szStringA is equal to “continue,” the result is TRUE and MessageBox is called. If szStringA is not equal to “continue,” the program moves to the next elseif, and so on.

```

if szStringA = "exit" then
    AskYesNo ("Are you sure you want to exit?", NO );
elseif szStringA = "continue" then
    MessageBox ("Please wait...", INFORMATION );
elseif szStringA = "reboot" then
    goto StartHere;
endif;

```

---

**Note** • You cannot define a label within an if statement.

## method

---

**Project** • This information applies to InstallScript projects.

The method keyword is used to declare a method in an object script with the following syntax:

```
method <return variable type> <method name> ( <argument variable type(s)> );
```

For example:

```
method STRING MyMethod ( STRING, NUMBER );
```

If you add a method to the object project by using the Add New Method dialog box, a method declaration is automatically placed in the object script.

## property()

**Project** ▪ This information applies to InstallScript projects.

The `property()` keyword is used to declare a property and its get and/or put procedures in an object script with the following syntax:

**Table 1** ▪ Property() Keyword Declarations

| Access            | Declaration                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Read only</b>  | <code>property(get) &lt;return variable type&gt; &lt;property name&gt; ( &lt;argument variable type(s)&gt; );</code>     |
| <b>Write only</b> | <code>property(put) &lt;return variable type&gt; &lt;property name&gt; ( &lt;argument variable type(s)&gt; );</code>     |
| <b>Read/write</b> | <code>property(get,put) &lt;return variable type&gt; &lt;property name&gt; ( &lt;argument variable type(s)&gt; );</code> |

For example:

```
property(get,put) STRING MyProperty ( NUMBER );
```

If you add a property to the object project by using the Add New Property dialog box, a property declaration is automatically placed in the object script.

## prototype

The `prototype` keyword tells the InstallScript compiler that the line of code contains a function definition. To learn how to use this keyword, see Declaring Functions.

## repeat...until

The `repeat` statement is analogous to the `do...while` loop in the C language. It also is very similar to the InstallScript `while` statement.

There are two main differences between `repeat` and `while` in InstallScript:

- The `repeat` statement must loop at least once. A `while` statement might not loop at all.
- A `while` statement terminates when the expression evaluates as false. A `repeat` statement terminates when the expression evaluates as true.

**Task****To create a repeat loop:**

1. Set the variable you will be using in the conditional test as you would for a while loop.
2. Type repeat on its own line with no punctuation.
3. Build the operation(s) that you want repeated.
4. Add the operation that changes the test variable (for example, nCount = nCount + 1, or nCount = SomeVariable).
5. End the loop with an until statement containing the conditional test in parentheses.

The following example demonstrates repeat loop syntax:

```
nCount = 1;
repeat
    MessageBox("Count is less than 5", INFORMATION);
    nCount = nCount + 1;
until (nCount = 5);
```

**Note** - You cannot define a label within the repeat statement.

## return

You can use the return statement to return a value from a user-defined function (if the function prototype does not specify a return type of void). When a return statement is encountered, program flow returns to the point at which the function was called. When used to return from a call to a user-defined function, the return statement can return a specified value to the caller.

The return value of most built-in functions will be either 0 (zero), indicating the success of the function, or a value less than zero (< 0), indicating failure. You can assign a number to the return value by using a return statement above the end statement in the function block, as shown below:

```
return -1;
end;
```

This attribute allows you to return the value of a local variable to the caller, even though the local variable itself is destroyed:

```
function MyFunction(ParamOne, ParamTwo)
    NUMBER nNumber;
begin
    nNumber = (ParamOne + ParamTwo);
    // . . .
    return nNumber;
end;
```

## set

The set keyword must precede the assignment of an OBJECT variable to a reference returned by the [CreateObject](#) function. For example:

```
function OnBegin( )
    OBJECT oMSI;
begin
    // create the object
    set oMSI = CreateObject("WindowsInstaller.Installer");

    // use the object (display MSI version on user's system)
    MessageBox("Your MSI version is: " + oMSI.Version, INFORMATION);

    // free the object
    set oMSI = NOTHING;
end;
```

**Note** • You can use the keywords `try-catch-endcatch` for more control over exception handling for COM objects.

## stdcall

**Project** • This information applies to InstallScript projects. The `stdcall` keyword is used when declaring an external DLL function that uses the `stdcall` calling convention. For example:

```
prototype stdcall POINTER kernel32.lstrcpy( byref string, byref string);
```

If no calling convention is specified, `stdcall` is assumed.

Most Windows API functions use the `stdcall` (WINAPI) calling convention. Consult Microsoft documentation for more information about calling conventions.

## switch...endswitch

The `switch` statement is similar to the `elseif Structure` statement. Use the `switch` statement to execute one of several different sections of code, depending on the value of an expression. The `switch` statement evaluates the expression and then branches to the case statement whose constant value matches the result of the expression. If no match is found among the case statements, control passes to a default statement, if one has been specified.

### Creating Switch Statements

#### Task

#### To create a switch statement:

1. Type the keyword `switch`, followed by the expression to be evaluated. The expression—which can be a constant, variable, arithmetic expression, logical expression, or function result—must be enclosed within parentheses. Do not punctuate this line.
2. For each option, type the keyword `case` and one or more constants followed by a colon. If more than one constant is specified, delimit them with commas. Note that only constants can be specified here. Specifying a variable name, string identifier, function result, or other type of expression after the keyword `case` results in an error.

3. For each case, follow the colon with the statement or statements to be executed for that option. Terminate each statement with a semicolon.
4. After all case statements have been specified, use the keyword *default*, followed by a colon (:), to control the program when the expression does not match any of the stated cases.
5. Close the block with the keyword *endswitch*, followed by a semicolon (;).

## Example Script

The following script segment displays the current video resolution of the computer on which it is executed:

```

STRING szMsg, svResult;
NUMBER nvResult;

GetSystemInfo (VIDEO, nvResult, svResult);

switch (nvResult)
    case IS_UNKNOWN:
        szMsg = "The user's video is unknown.";
    case IS_EGA:
        szMsg = "EGA resolution.";
    case IS_VGA:
        szMsg = "VGA resolution.";
    case IS_SVGA:
        szMsg = "Super VGA (800 x 600) resolution.";
    case IS_XVGA:
        szMsg = "XVGA (1024 x 768) resolution.";
    case IS_UVGA:
        szMsg = "Greater than 1024 x 768 resolution.";
    default:
        szMsg = "Error";
endswitch;

MessageBox (szMsg, INFORMATION);

```

---

**Note** ▪ Only one case block is executed each time a switch statement is executed. After InstallShield executes a case block, it executes the next statement after the endswitch. A switch block can be quite useful inside of a while loop. By using the case statements as flags, you can create a loop with optional exit points.

## try, catch, and endcatch

The keywords try, catch, and endcatch are used for exception handling. For more information on exception handling, see [Exception Handling](#).

---

**Note** ▪ You cannot use a goto statement within a try...catch...endcatch statement. In addition, you cannot define a label within a try...catch...endcatch statement.

## void

Void is not a true data type, in the sense that a variable cannot be declared as type void. Void is only used in function prototypes to indicate that the function does not return a value, as in the following:

```
prototype void Subroutine(int);

function void Subroutine(int);
begin
    // perform operations, but
    // do not return a value
end;
```

## while...endwhile

Use the while statement when you want to execute one or more statements repeatedly, as long as a particular condition is true. If the condition is not true when the statement is first executed, the loop is not performed.

### Task

#### To create a while loop:

1. Set the variable you are using as the condition to an initial state.
2. Type the keyword while, followed by the conditional test in parentheses. Do not punctuate this line.
3. Build the operation(s) that you want repeated.
4. Add the operation that changes the test variable (for example, nCount = nCount + 1, or nCount = SomeVariable).
5. End the loop by typing endwhile, followed by a semicolon.

In the following example, the message box is displayed four times.

```
nCount = 1;

while (nCount < 5)
    MessageBox ("This is still true.", INFORMATION);
    nCount = nCount + 1;
endwhile;
```

Because nCount is assigned an initial value of 1, the while statement evaluates TRUE the first time it is executed; the message box is displayed and nCount is incremented by 1. After the fourth pass through the loop, nCount is equal to 5; the while statement evaluates FALSE and the program continues executing with the statement after endwhile.

**Note** • You cannot define a label within a while block. You can, however, nest while statements in InstallScript. You must end each while block with endwhile.

## Nested while Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/* This script illustrates a nested while loop.
 * It searches for the specified type of files and
 * shows the number of lines in each file.      */

#define SOURCEDIR "c:\\example";

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_Nested while(HWND);

function ExFn_Nested while(hMSI)
    LIST    listID;
    STRING  svTarget, svResult, filename, svLine, szPath, szFileName;
    NUMBER  nResult, nOp,nFileHandle,count;
begin

    count = 0;
    nOp = RESET;
    svTarget = SOURCEDIR;
    listID = ListCreate (STRINGLIST);

    while FindAllFiles (svTarget, "*.txt", svResult, nOp) = 0;

        // To get the name of the file in the fully specified path
        StrGetTokens(listID,svResult,"\\");
        ListCurrentString(listID,filename);

        // Set the file mode to normal.
        OpenFileMode(FILE_MODE_NORMAL);
        szFileName = filename;
        szPath      = svTarget;

        // The following opens the file for editing.
        OpenFile(nFileHandle, szPath, szFileName);

/*-----*\
 *
 * The following retrieves each line of text from the open file and increments
 * a count to find the number of lines.
 *
 \*-----*/

        while (GetLine (nFileHandle, svLine) = 0)
            count = count + 1;
        endwhile;

        SprintfBox(INFORMATION,"The Total lines in the file",
            "The  No. of lines in the file %s is %d",filename,count);
```

```

count = 0;

// The following closes the file
CloseFile(nFileHandle);

// Continue searching files where last file was left off
nOp = CONTINUE;

if (FindAllFiles (svTarget, "*.txt", svResult, nOp) < 0) then
    abort;
endif;

endwhile;

end;

```

## Flow Control

Like most programming languages, InstallScript processes statements within a function block sequentially, starting with the first statement and ending with the last. The linear flow of execution within a function block can be controlled with conditional statements that perform branching and iteration.

Branching is most commonly performed with an if statement that directs execution down one path or another. Iteration is performed with loop statements that execute one or more statements repeatedly, either for a set number of times or as long as a specified condition is met.

To control the flow of execution within scripts, InstallShield provides the following keywords:

- abort
- exit
- for...endfor
- goto
- if...then...else...endif
- repeat...until
- return
- switch...endswitch
- while...endwhile

# Predefined Constants

A predefined constant is an identifier reserved by InstallScript to represent a specific literal value. InstallScript uses predefined constants to represent certain data values that are passed to and returned by built-in functions. By using these predefined constants rather than literal values, you can improve the readability of your setup scripts.

You cannot change the value InstallShield assigns to a predefined constant. However, you can determine the value of a predefined constant by calling [SprintfBox](#), as shown in the example below, which displays the value of the predefined constant `FEATURE_FIELD_SELECTED`:

```
SprintfBox (INFORMATION, "", "%d", FEATURE_FIELD_SELECTED);
```

Although you can use a literal value in place of a predefined constant, it is strongly recommended that you use predefined constants wherever indicated for a function.

Following is a list of the predefined constants used by InstallScript.

- 
- 
- 
- 

## AFTER

AFTER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [EzBatchAddString](#)
- [EzBatchAddPath](#)
- [ConfigAdd](#)
- [ConfigMove](#)
- [ListAddItem](#)
- [ListAddString](#)
- [PathAdd](#)
- [PathMove](#)
- [BatchAdd](#)
- [PathMove](#)
- [BatchMoveEx](#)
- [FileInsertLine](#)
- [EzConfigAddDriver](#)

- [EzConfigAddString](#)

## ALLCONTENTS

ALLCONTENTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DeleteDir](#)

## ALLCONTROLS

ALLCONTROLS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CtrlSetFont](#)

## APPEND

APPEND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FileInsertLine](#)

## ASKDESTPATH

ASKDESTPATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [AskDestPath](#)

## ASKOPTIONS

ASKOPTIONS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [AskOptions](#)
- [PlaceWindow](#)

# ASKPATH

ASKPATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [AskPath](#)
- [PlaceWindow](#)

# ASKTEXT

ASKTEXT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [AskText](#)
- [PlaceWindow](#)

# BACK

BACK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [AskDestPath](#)
- [AskOptions](#)
- [AskPath](#)
- [AskText](#)
- [FeatureDialog](#)
- [SdAskDestPath](#)
- [SdAskOptions](#)
- [SdAskOptionsList](#)
- [SdBitmap](#)
- [SdDisplayTopics](#)
- [SdFeatureDialog](#)
- [SdFeatureDialog2](#)
- [SdFeatureDialogAdv](#)
- [SdFeatureMult](#)

- [SdLicense](#)
- [SdOptionsButtons](#)
- [SdRegisterUser](#)
- [SdRegisterUserEx](#)
- [SdSelectFolder](#)
- [SdShowAnyDialog](#)
- [SdShowDlgEdit1](#)
- [SdShowDlgEdit2](#)
- [SdShowDlgEdit3](#)
- [SdShowFileMods](#)
- [SdShowInfoList](#)
- [SdStartCopy](#)
- [SdWelcome](#)
- [SelectFolder](#)
- [Welcome](#)

## BACKBUTTON

BACKBUTTON is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Disable](#)
- [Enable](#)
- [Is](#)

## BACKGROUND

BACKGROUND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceWindow](#)
- [SetColor](#)
- [Enable](#)
- [SizeWindow](#)

- [Disable](#)

## BACKGROUNDCAPTION

BACKGROUNDCAPTION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetTitle](#)

## BASEMEMORY

**Project** ▪ This information applies to InstallScript projects.

BASEMEMORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## BEFORE

BEFORE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PathMove](#)
- [FileInsertLine](#)
- [EzBatchAddPath](#)
- [EzBatchAddString](#)
- [BatchAdd](#)
- [BatchMoveEx](#)
- [EzConfigAddDriver](#)
- [EzConfigAddString](#)
- [ConfigAdd](#)
- [ConfigMove](#)
- [ListAddItem](#)
- [ListAddString](#)

- [PathAdd](#)

## BIF\_BROWSEFORCOMPUTER

**Project** ▪ This information applies to InstallScript projects.

BIF\_BROWSEFORCOMPUTER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDirEx](#)

## BIF\_BROWSEFORPRINTER

**Project** ▪ This information applies to InstallScript projects.

BIF\_BROWSEFORPRINTER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDirEx](#)

## BIF\_DONTGOBELOWDOMAIN

**Project** ▪ This information applies to InstallScript projects.

BIF\_DONTGOBELOWDOMAIN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDirEx](#)

## BIF\_EDITBOX

**Project** ▪ This information applies to InstallScript projects.

BIF\_EDITBOX is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDirEx](#)

## BIF\_RETURNFSANCESTORS

---

**Project** • This information applies to InstallScript projects.

BIF\_RETURNFSANCESTORS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDirEx](#)

## BIF\_RETURNONLYFSDIRS

---

**Project** • This information applies to InstallScript projects.

BIF\_RETURNONLYFSDIRS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDirEx](#)

## BIF\_STATUSTEXT

---

**Project** • This information applies to InstallScript projects.

BIF\_STATUSTEXT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDirEx](#)

## BILLBOARD

BILLBOARD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Disable](#)
- [PlaceWindow](#)

## BITMAPICON

BITMAPICON is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [PlaceBitmap](#)

## BK\_BLUE

BK\_BLUE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_GREEN

BK\_GREEN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_MAGENTA

BK\_MAGENTA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_ORANGE

BK\_ORANGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_PINK

BK\_PINK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_RED

BK\_RED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SMOOTH

BK\_SMOOTH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDBLACK

BK\_SOLIDBLACK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDBLUE

BK\_SOLIDBLUE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDGREEN

BK\_SOLIDGREEN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDMAGENTA

BK\_SOLIDMAGENTA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDORANGE

BK\_SOLIDORANGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDPINK

BK\_SOLIDPINK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDRED

BK\_SOLIDRED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDWHITE

BK\_SOLIDWHITE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_SOLIDYELLOW

BK\_SOLIDYELLOW is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BK\_YELLOW

BK\_YELLOW is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## BLACK

BLACK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetTitle](#)

## BLUE

BLUE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)
- [SetTitle](#)

## BOOTUPDRIVE

BOOTUPDRIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetSystemInfo](#)

## BUTTON\_CHECKED

BUTTON\_CHECKED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [CtrlSetState](#)
- [CtrlGetState](#)

## BUTTON\_UNCHECKED

BUTTON\_UNCHECKED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [CtrlSetState](#)
- [CtrlGetState](#)

## BYTES

BYTES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ConvertSizeToUnits](#)
- [StrConvertSizeUnit](#)

# CANCEL

CANCEL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [SelectDir](#)

# CANCELBUTTON

CANCELBUTTON is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [Disable](#)
- [Enable](#)
- [Is](#)

# CDROM

CDROM is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetSystemInfo](#)

# CDROM\_DRIVE

CDROM\_DRIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetValidDrivesList](#)

# CENTERED

CENTERED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [PlaceWindow](#)

- [PlaceBitmap](#)

## CHECKBOX

CHECKBOX is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DialogSetInfo](#)

## CHECKBOX95

CHECKBOX95 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DialogSetInfo](#)

## CHECKLINE

CHECKLINE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DialogSetInfo](#)

## CHECKMARK

CHECKMARK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DialogSetInfo](#)

## CLEAR\_FILE\_ATTR

CLEAR\_FILE\_ATTR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [XCopyFile](#)

## COLORS

COLORS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## COMMAND

COMMAND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [BatchMoveEx](#)
- [ConfigFind](#)
- [EzBatchAddString](#)
- [BatchAdd](#)
- [BatchDeleteEx](#)

## COMMON

COMMON is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ProgDefGroupType](#)

## COMPACT

COMPACT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetupType](#)
- [SdSetupType](#)

## COMPARE\_DATE

COMPARE\_DATE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [FileCompare](#)

## COMPARE\_MD5\_SIGNATURE

COMPARE\_MD5\_SIGNATURE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [FileCompare](#)

## COMPARE\_SIZE

COMPARE\_SIZE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [FileCompare](#)

## COMPARE\_VERSION

COMPARE\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [FileCompare](#)

## COMP\_NORMAL

COMP\_NORMAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [XCopyFile](#)

## COMP\_UPDATE\_DATE

COMP\_UPDATE\_DATE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [XCopyFile](#)

## COMP\_UPDATE\_SAME

COMP\_UPDATE\_SAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [XCopyFile](#)

## COMP\_UPDATE\_VERSION

COMP\_UPDATE\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [XCopyFile](#)

## CONTINUE

CONTINUE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [FileGrep](#)
- [BatchFind](#)
- [FindFile](#)
- [ConfigFind](#)
- [PathFind](#)

## COPY\_ERR\_CREATEDIR

COPY\_ERR\_CREATEDIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [CopyFile](#)
- [XCopyFile](#)

## COPY\_ERR\_MEMORY

COPY\_ERR\_MEMORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CopyFile](#)
- [XCopyFile](#)

## COPY\_ERR\_NODISKSPACE

COPY\_ERR\_NODISKSPACE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CopyFile](#)
- [XCopyFile](#)

## COPY\_ERR\_OPENINPUT

COPY\_ERR\_OPENINPUT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CopyFile](#)
- [XCopyFile](#)

## COPY\_ERR\_OPENOUTPUT

COPY\_ERR\_OPENOUTPUT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CopyFile](#)
- [XCopyFile](#)

## COPY\_ERR\_TARGETREADONLY

COPY\_ERR\_TARGETREADONLY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [CopyFile](#)
- [XCopyFile](#)

## CPU

CPU is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetSystemInfo](#)

## CS\_OPTION\_FLAG\_NO\_NEW\_INSTALL\_HIGHLIGHT

CS\_OPTION\_FLAG\_NO\_NEW\_INSTALL\_HIGHLIGHT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [CreateShortcut](#)
- [ReplaceShortcut](#)

## CS\_OPTION\_FLAG\_NO\_STARTSCREEN\_PIN

CS\_OPTION\_FLAG\_NO\_STARTSCREEN\_PIN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [CreateShortcut](#)
- [ReplaceShortcut](#)

## CS\_OPTION\_FLAG\_PREVENT\_PINNING

CS\_OPTION\_FLAG\_PREVENT\_PINNING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [CreateShortcut](#)
- [ReplaceShortcut](#)

## CS\_OPTION\_FLAG\_REPLACE\_EXISTING

CS\_OPTION\_FLAG\_REPLACE\_EXISTING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CreateShortcut](#)
- [ReplaceShortcut](#)

## CS\_OPTION\_FLAG\_RUN\_MAXIMIZED

CS\_OPTION\_FLAG\_RUN\_MAXIMIZED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CreateShortcut](#)
- [ReplaceShortcut](#)

## CS\_OPTION\_FLAG\_RUN\_MINIMIZED

CS\_OPTION\_FLAG\_RUN\_MINIMIZED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CreateShortcut](#)
- [ReplaceShortcut](#)

## CURRENTROOTKEY

CURRENTROOTKEY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VarRestore](#)
- [VarSave](#)

## CUSTOM

CUSTOM is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetupType](#)
- [SdSetupType](#)

## DATA\_COMPONENT

DATA\_COMPONENT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SilentReadData](#)
- [SilentWriteData](#)

## DATA\_LIST

DATA\_LIST is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SilentWriteData](#)

## DATA\_NUMBER

DATA\_NUMBER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SilentReadData](#)
- [SilentWriteData](#)

## DATA\_STRING

DATA\_STRING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SilentReadData](#)
- [SilentWriteData](#)

# DATE

DATE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- `GetSystemInfo`

# DEFAULT

DEFAULT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- `switch...endswitch`

# DEFWINDOWMODE

DEFWINDOWMODE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- `Enable`

# DELETE

---

**Project** • This information applies to InstallScript projects.

DELETE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- `SetObjectPermissions`
- `SERVICE_IS_PARAMS`

# DELETE\_EOF

DELETE\_EOF is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [FileDeleteLine](#)

## DIALOGCACHE

DIALOGCACHE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Disable](#)
- [Enable](#)

## DIFXAPI\_ERROR

DIFXAPI\_ERROR is a predefined constant that is used to represent a value that is available for use with one or more event handlers. You cannot change the value of a predefined constant.

**Used With**

- [OnDIFxLogCallback](#)

## DIFXAPI\_INFO

DIFXAPI\_INFO is a predefined constant that is used to represent a value that is available for use with one or more event handlers. You cannot change the value of a predefined constant.

**Used With**

- [OnDIFxLogCallback](#)

## DIFXAPI\_SUCCESS

DIFXAPI\_SUCCESS is a predefined constant that is used to represent a value that is available for use with one or more event handlers. You cannot change the value of a predefined constant.

**Used With**

- [OnDIFxLogCallback](#)

## DIFXAPI\_WARNING

DIFXAPI\_WARNING is a predefined constant that is used to represent a value that is available for use with one or more event handlers. You cannot change the value of a predefined constant.

### Used With

- [OnDIFxLogCallback](#)

## DIRECTORY

DIRECTORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ParsePath](#)

## DIR\_WRITEABLE

DIR\_WRITEABLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Is](#)

## DISABLE\_ALLUSERBTN

---

**Project** ▪ This information applies to InstallScript projects.

DISABLE\_ALLUSERBTN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

The DISABLE\_ALLUSERBTN constant indicates that the all-users option should be disabled (or hidden) in cases where it would normally be enabled. The default value of this variable is FALSE. Note that the all-users option is always hidden if the installation is being run without administrator or power-user privileges, regardless of the value of this variable.

### Used With

- [SdCustomerInformation](#)
- [SdCustomerInformationEx](#)

## DISABLE\_PERUSERBTN

DISABLE\_PERUSERBTN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

The `DISABLE_PERUSERBTN` constant indicates that the per-user option should be disabled (or hidden if `HIDE_DISABLED_BTNS` is `TRUE`) in cases where it would normally be enabled. The default value of this variable is `FALSE`. Note that the per-user option is always hidden on Windows 9x platforms, regardless of the value of this variable.

### Used With

- `SdCustomerInformation`
- `SdCustomerInformationEx`

## DISK

`DISK` is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `ParsePath`

## DISK1FEATURE

**Project** - This information applies to *InstallScript* projects.

`DISK1FEATURE` is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

`DISK1FEATURE` specifies the feature with the files needed for maintenance setups and uninstallation. (Note that this feature is automatically placed in your `.cab` files by the media builder and is not displayed in the IDE.)

### Used With

- `FeatureSelectItem`
- `FeatureIsItemSelected`

## DISK\_INFO\_QUERY\_ALL

`DISK_INFO_QUERY_ALL` is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `GetDiskInfo`

## DISK\_INFO\_QUERY\_BYTES\_PER\_CLUSTER

DISK\_INFO\_QUERY\_BYTES\_PER\_CLUSTER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetDiskInfo](#)

## DISK\_INFO\_QUERY\_DISK\_FREE\_SPACE

DISK\_INFO\_QUERY\_DISK\_FREE\_SPACE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetDiskInfo](#)

## DISK\_INFO\_QUERY\_DISK\_TOTAL\_SPACE

DISK\_INFO\_QUERY\_DISK\_TOTAL\_SPACE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetDiskInfo](#)

## DISK\_INFO\_QUERY\_DRIVE\_TYPE

DISK\_INFO\_QUERY\_DRIVE\_TYPE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetDiskInfo](#)

## DISK\_TOTALSPACE

DISK\_TOTALSPACE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## DISK\_TOTALSPACE\_EX

DISK\_TOTALSPACE\_EX is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## DLG\_ASK\_OPTIONS

DLG\_ASK\_OPTIONS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_ASK\_PATH

DLG\_ASK\_PATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_ASK\_TEXT

DLG\_ASK\_TEXT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_ASK\_YESNO

DLG\_ASK\_YESNO is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_CENTERED

DLG\_CENTERED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DefineDialog](#)

## DLG\_CLOSE

DLG\_CLOSE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [WaitOnDialog](#)

## DLG\_DIR\_DIRECTORY

DLG\_DIR\_DIRECTORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CtrlDir](#)

## DLG\_DIR\_DRIVE

DLG\_DIR\_DRIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CtrlDir](#)

## DLG\_DIR\_FILE

DLG\_DIR\_FILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CtrlDir](#)

## DLG\_ENTER\_DISK

DLG\_ENTER\_DISK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_ERR

DLG\_ERR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [WaitOnDialog](#)
- [EzDefineDialog](#)
- [ReleaseDialog](#)
- [CtrlGetState](#)
- [DefineDialog](#)

## DLG\_ERR\_ALREADY\_EXISTS

DLG\_ERR\_ALREADY\_EXISTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DefineDialog](#)
- [EzDefineDialog](#)

## DLG\_ERR\_ENDDLG

DLG\_ERR\_ENDDLG is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ReleaseDialog](#)

## DLG\_INFO\_ALTIMAGE

DLG\_INFO\_ALTIMAGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [DialogSetInfo](#)

## DLG\_INFO\_ALTIMAGE\_HIDPI

DLG\_INFO\_ALTIMAGE\_HIDPI is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [DialogSetInfo](#)

## DLG\_INFO\_ALTIMAGE\_REVERT\_IMAGE

DLG\_INFO\_ALTIMAGE\_REVERT\_IMAGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [DialogSetInfo](#)

## DLG\_INFO\_ALTIMAGE\_VERIFY\_BMP

DLG\_INFO\_ALTIMAGE\_VERIFY\_BMP is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [DialogSetInfo](#)

## DLG\_INFO\_CHECKSELECTION

This constant is now obsolete. The checkbox controls in InstallScript are now drawn automatically using your current Windows theme to provide a modern and uniform look that is compatible with high DPI displays.

## DLG\_INFO\_KUNITS

DLG\_INFO\_KUNITS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [DialogSetInfo](#)

## DLG\_INFO\_USEDECIMAL

DLG\_INFO\_USEDECIMAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DialogSetInfo](#)

## DLG\_INIT

DLG\_INIT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [WaitOnDialog](#)

## DLG\_MSG\_ALL

DLG\_MSG\_ALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DefineDialog](#)

## DLG\_MSG\_INFORMATION

DLG\_MSG\_INFORMATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_MSG\_SEVERE

DLG\_MSG\_SEVERE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_MSG\_STANDARD

DLG\_MSG\_STANDARD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DefineDialog](#)

## DLG\_MSG\_WARNING

DLG\_MSG\_WARNING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_STATUS

DLG\_STATUS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DLG\_USER\_CAPTION

DLG\_USER\_CAPTION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetDialogTitle](#)

## DOINSTALL\_OPTION\_NOHIDEPROGRESS

DOINSTALL\_OPTION\_NOHIDEPROGRESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)

## DOINSTALL\_OPTION\_NOHIDESPLASH

DOINSTALL\_OPTION\_NOHIDESPLASH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `DoInstall`

## DOINSTALL\_OPTION\_NOLANGSWITCH

DOINSTALL\_OPTION\_NOLANGSWITCH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `DoInstall`

## DOINSTALL\_OPTION\_NOSETBATCHINSTALL

DOINSTALL\_OPTION\_NOSETBATCHINSTALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `DoInstall`

## DOTNETFRAMEWORKINSTALLED

DOTNETFRAMEWORKINSTALLED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Is`

## DOTNETSERVICEPACKINSTALLED

DOTNETSERVICEPACKINSTALLED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Is`

# DRIVE

DRIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetSystemInfo](#)

# DRIVE\_CDROM

DRIVE\_CDROM is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetDiskInfo](#)

# DRIVE\_FIXED

DRIVE\_FIXED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetDiskInfo](#)

# DRIVE\_NO\_ROOT\_DIR

DRIVE\_NO\_ROOT\_DIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetDiskInfo](#)

# DRIVE\_RAMDISK

DRIVE\_RAMDISK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetDiskInfo](#)

## DRIVE\_REMOTE

DRIVE\_REMOTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetDiskInfo](#)

## DRIVE\_REMOVABLE

DRIVE\_REMOVABLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetDiskInfo](#)

## DRIVE\_UNKNOWN

DRIVE\_UNKNOWN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetDiskInfo](#)

## DRIVER\_PACKAGE\_DELETE\_FILES

DRIVER\_PACKAGE\_DELETE\_FILES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DIFxDriverPackageUninstall](#)

## DRIVER\_PACKAGE\_FORCE

DRIVER\_PACKAGE\_FORCE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackagePreinstall](#)
- [DIFxDriverPackageUninstall](#)

## DRIVER\_PACKAGE\_LEGACY\_MODE

DRIVER\_PACKAGE\_LEGACY\_MODE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackagePreinstall](#)

## DRIVER\_PACKAGE\_ONLY\_IF\_DEVICE\_PRESENT

DRIVER\_PACKAGE\_ONLY\_IF\_DEVICE\_PRESENT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackagePreinstall](#)

## DRIVER\_PACKAGE\_REPAIR

DRIVER\_PACKAGE\_REPAIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackagePreinstall](#)
- [DIFxDriverPackageUninstall](#)

## DRIVER\_PACKAGE\_SILENT

DRIVER\_PACKAGE\_SILENT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackagePreinstall](#)

## EDITBOX\_CHANGE

EDITBOX\_CHANGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [CtrlGetSubCommand](#)

## EFF\_BOXSTRIPE

EFF\_BOXSTRIPE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetDisplayEffect](#)

## EFF\_FADE

EFF\_FADE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetDisplayEffect](#)

## EFF\_HORZREVEAL

EFF\_HORZREVEAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetDisplayEffect](#)

## EFF\_HORZSTRIPE

EFF\_HORZSTRIPE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetDisplayEffect](#)

## EFF\_NONE

EFF\_NONE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetDisplayEffect](#)

## EFF\_REVEAL

EFF\_REVEAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetDisplayEffect](#)

## EFF\_VERTSTRIPE

EFF\_VERTSTRIPE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetDisplayEffect](#)

## END\_OF\_FILE

END\_OF\_FILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [FileGrep](#)

## END\_OF\_LIST

END\_OF\_LIST is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ListCurrentItem](#)
- [ListCurrentString](#)
- [ListGetFirstItem](#)
- [ListSetIndex](#)
- [ListDeleteItem](#)
- [ListDeleteString](#)
- [ListFindItem](#)

- [ListFindString](#)
- [ListCurrentString](#)
- [ListGetNextItem](#)
- [ListGetNextString](#)
- [ListSetCurrentItem](#)
- [ListSetCurrentString](#)

## ENTERDISK

ENTERDISK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [EnterDisk](#)
- [PlaceWindow](#)

## EQUALS

EQUALS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerCompare](#)
- [FileCompare](#)

## ERROR\_ACCESS\_DENIED

---

**Project** • This information applies to InstallScript projects.

ERROR\_ACCESS\_DENIED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_CIRCULAR\_DEPENDENCY

**Project** ▪ This information applies to InstallScript projects.

ERROR\_CIRCULAR\_DEPENDENCY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_DATABASE\_DOES\_NOT\_EXIST

**Project** ▪ This information applies to InstallScript projects.

ERROR\_DATABASE\_DOES\_NOT\_EXIST is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_DEPENDENT\_SERVICES\_RUNNING

**Project** ▪ This information applies to InstallScript projects.

ERROR\_DEPENDENT\_SERVICES\_RUNNING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_DUP\_NAME

**Project** ▪ This information applies to InstallScript projects.

ERROR\_DUP\_NAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

# ERROR\_FILE\_NOT\_FOUND

**Project** ▪ This information applies to InstallScript projects.

ERROR\_FILE\_NOT\_FOUND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetExtendedErrInfo](#)

# ERROR\_INVALID\_HANDLE

**Project** ▪ This information applies to InstallScript projects.

ERROR\_INVALID\_HANDLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetExtendedErrInfo](#)

# ERROR\_INVALID\_PARAMETER

**Project** ▪ This information applies to InstallScript projects.

ERROR\_INVALID\_PARAMETER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetExtendedErrInfo](#)

# ERROR\_INVALID\_SERVICE\_ACCOUNT

**Project** ▪ This information applies to InstallScript projects.

ERROR\_INVALID\_SERVICE\_ACCOUNT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetExtendedErrInfo](#)

## ERROR\_INVALID\_SERVICE\_CONTROL

**Project** ▪ This information applies to InstallScript projects.

ERROR\_INVALID\_SERVICE\_CONTROL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_PATH\_NOT\_FOUND

**Project** ▪ This information applies to InstallScript projects.

ERROR\_PATH\_NOT\_FOUND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_ALREADY\_RUNNING

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_ALREADY\_RUNNING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_CANNOT\_ACCEPT\_CTRL

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_CANNOT\_ACCEPT\_CTRL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_DATABASE\_LOCKED

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_DATABASE\_LOCKED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_DEPENDENCY\_DELETED

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_DEPENDENCY\_DELETED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_DEPENDENCY\_FAIL

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_DEPENDENCY\_FAIL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_DISABLED

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_DISABLED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_DOES\_NOT\_EXIST

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_DOES\_NOT\_EXIST is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_EXISTS

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_EXISTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_LOGON\_FAILED

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_LOGON\_FAILED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

## ERROR\_SERVICE\_NOT\_ACTIVE

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_NOT\_ACTIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetExtendedErrInfo](#)

# ERROR\_SERVICE\_NO\_THREAD

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_NO\_THREAD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetExtendedErrInfo](#)

# ERROR\_SERVICE\_REQUEST\_TIMEOUT

**Project** ▪ This information applies to InstallScript projects.

ERROR\_SERVICE\_REQUEST\_TIMEOUT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetExtendedErrInfo](#)

# ERROR\_TIMEOUT

**Project** ▪ This information applies to InstallScript projects.

ERROR\_TIMEOUT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetExtendedErrInfo](#)

# ERR\_ABORT

ERR\_ABORT is a predefined constant that is used to represent a value that is passed to or returned by one or more event handlers. You cannot change the value of a predefined constant.

## Used With

- [OnNextDisk](#)

## ERR\_BOX\_BADPATH

ERR\_BOX\_BADPATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetErrorMsg](#)
- [SetErrorTitle](#)

## ERR\_BOX\_BADTAGFILE

ERR\_BOX\_BADTAGFILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetErrorMsg](#)
- [SetErrorTitle](#)

## ERR\_BOX\_DISKID

ERR\_BOX\_DISKID is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetErrorTitle](#)
- [SetErrorMsg](#)

## ERR\_BOX\_DRIVEOPEN

ERR\_BOX\_DRIVEOPEN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetErrorTitle](#)
- [SetErrorMsg](#)

## ERR\_IGNORE

ERR\_IGNORE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or event handlers. You cannot change the value of a predefined constant.

**Used With**

- [SdExceptions](#)

## ERR\_NO

ERR\_NO is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or event handlers. You cannot change the value of a predefined constant.

**Used With**

- [SdExceptions](#)

## ERR\_PERFORM\_AFTER\_REBOOT

ERR\_PERFORM\_AFTER\_REBOOT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or event handlers. You cannot change the value of a predefined constant.

**Used With**

- [SdExceptions](#)

## ERR\_RETRY

ERR\_RETRY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or event handlers. You cannot change the value of a predefined constant.

**Used With**

- [OnNextDisk](#)
- [SdExceptions](#)

## ERR\_YES

ERR\_YES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or event handlers. You cannot change the value of a predefined constant.

**Used With**

- [SdExceptions](#)

## EXCLUDE\_SUBDIR

EXCLUDE\_SUBDIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [XCopyFile](#)
- [FindAllDirs](#)

## EXCLUSIVE

EXCLUSIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SdAskOptionsList](#)
- [AskOptions](#)
- [SdAskOptions](#)

## EXISTS

EXISTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ExistsDir](#)
- [ExistsDisk](#)

## EXIT

EXIT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Do](#)
- [HandlerEx](#)

## EXTENDEDMEMORY

EXTENDEDMEMORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetSystemInfo](#)

## EXTENSION\_ONLY

EXTENSION\_ONLY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ParsePath](#)

## FALSE

FALSE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [AskOptions](#)
- [CtrlSetMultCurSel](#)
- [DialogSetInfo](#)
- [FeatureAddItem](#)
- [FeatureGetData](#)
- [FeatureIsItemSelected](#)
- [FeatureSelectItem](#)
- [FeatureTotalSize](#)
- [LongPathToQuote](#)
- [SdDiskSpace2](#)
- [SelectDir](#)
- [SdShowMsg](#)
- [SQLDatabaseBrowse](#)
- [SQLRTConnect](#)
- [SQLRTConnect2](#)
- [SQLRTConnectDB](#)
- [SQLRTGetDatabases](#)
- [SQLRTGetServers](#)
- [SQLRTGetServers2](#)
- [SQLRTPutConnectionAuthentication](#)
- [SQLRTTestConnection](#)
- [SQLRTTestConnection2](#)

- [SQLServerSelectLogin](#)
- [SQLServerSelectLogin2](#)

## FEATURE\_FIELD\_CDROM\_FOLDER

---

**Project** ▪ This information applies to *InstallScript* projects.

FEATURE\_FIELD\_CDROM\_FOLDER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)

## FEATURE\_FIELD\_DESCRIPTION

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_DESCRIPTION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)
- [FeatureSetData](#)

## FEATURE\_FIELD\_DISPLAYNAME

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_DISPLAYNAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)
- [FeatureSetData](#)

# FEATURE\_FIELD\_ENCRYPT

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_FIELD\_ENCRYPT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureGetData](#)
- [FeatureSetData](#)

# FEATURE\_FIELD\_FILENEED

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_FIELD\_FILENEED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureGetData](#)

# FEATURE\_FIELD\_FLAGS

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_FIELD\_FLAGS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureGetData](#)

# FEATURE\_FIELD\_FTPLOCATION

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_FTPLOCATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)

## FEATURE\_FIELD\_GUID

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_FIELD\_GUID is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)

## FEATURE\_FIELD\_HANDLER\_ONINSTALLED

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_HANDLER\_ONINSTALLED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)

## FEATURE\_FIELD\_HANDLER\_ONINSTALLING

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_HANDLER\_ONINSTALLING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)

# FEATURE\_FIELD\_HANDLER\_ONUNINSTALLED

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_HANDLER\_ONUNINSTALLED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- *FeatureGetData*

# FEATURE\_FIELD\_HANDLER\_ONUNINSTALLING

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_HANDLER\_ONUNINSTALLING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- *FeatureGetData*

# FEATURE\_FIELD\_HTTPLOCATION

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_HTTPLOCATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- *FeatureGetData*

## FEATURE\_FIELD\_IMAGE

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_IMAGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureSetData](#)

## FEATURE\_FIELD\_MISC

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_MISC is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)
- [FeatureSetData](#)

## FEATURE\_FIELD\_PASSWORD

**Project** ▪ This information applies to *InstallScript* projects.

FEATURE\_FIELD\_PASSWORD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)

# FEATURE\_FIELD\_SELECTED

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_SELECTED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureGetData](#)
- [FeatureSetData](#)

# FEATURE\_FIELD\_SIZE

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_SIZE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureGetData](#)
- [FeatureSetData](#)

# FEATURE\_FIELD\_STATUS

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_STATUS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureGetData](#)
- [FeatureSetData](#)

## FEATURE\_FIELD\_VISIBLE

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_FIELD\_VISIBLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- *FeatureGetData*
- *FeatureSetData*

## FEATURE\_INFO\_ATTRIBUTE

---

**Project** ▪ This information applies to InstallScript MSI projects.

FEATURE\_INFO\_ATTRIBUTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- *FeatureFileInfo*

## FEATURE\_INFO\_COMPONENT\_FLAGS

---

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_INFO\_COMPONENT\_FLAGS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- *FeatureFileInfo*

## FEATURE\_INFO\_COMPSIZE\_HIGH

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_COMPSIZE\_HIGH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_COMPSIZE\_LOW

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_COMPSIZE\_LOW is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_DATE

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_INFO\_DATE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_DATE\_EX

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_INFO\_DATE\_EX is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_DESTINATION

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_DESTINATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_FTPLOCATION

---

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_INFO\_FTPLOCATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_HTTPLOCATION

---

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_INFO\_HTTPLOCATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

# FEATURE\_INFO\_LANGUAGE

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_LANGUAGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- *FeatureFileInfo*

# FEATURE\_INFO\_MD5\_SIGNATURE

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_MD5\_SIGNATURE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- *FeatureFileInfo*

# FEATURE\_INFO\_MISC

**Project** ▪ This information applies to *InstallScript* projects.

FEATURE\_INFO\_MISC is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- *FeatureFileInfo*

## FEATURE\_INFO\_ORIGSIZE\_HIGH

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_ORIGSIZE\_HIGH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- *FeatureFileInfo*

## FEATURE\_INFO\_ORIGSIZE\_LOW

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_ORIGSIZE\_LOW is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- *FeatureFileInfo*

## FEATURE\_INFO\_OS

**Project** ▪ This information applies to *InstallScript* projects.

FEATURE\_INFO\_OS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- *FeatureFileInfo*

## FEATURE\_INFO\_OVERWRITE

**Project** ▪ This information applies to *InstallScript* projects.

FEATURE\_INFO\_OVERWRITE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_PLATFORM\_SUITE

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_INFO\_PLATFORM\_SUITE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_TIME

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_INFO\_TIME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_VERSIONLS

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_VERSIONLS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_VERSIONMS

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_VERSIONMS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_INFO\_VERSIONSTR

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

FEATURE\_INFO\_VERSIONSTR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [FeatureFileInfo](#)

## FEATURE\_OPCOST\_UNINSTALL\_FILE

FEATURE\_OPCOST\_UNINSTALL\_FILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureAddUninstallCost](#)
- [FeatureSpendUninstallCost](#)

## FEATURE\_OPCOST\_UNINSTALL\_REGORINI

FEATURE\_OPCOST\_UNINSTALL\_REGORINI is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureAddUninstallCost](#)
- [FeatureSpendUninstallCost](#)

## FEATURE\_OPCOST\_UNINSTALL\_UNREGFILE

FEATURE\_OPCOST\_UNINSTALL\_UNREGFILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureAddUninstallCost](#)
- [FeatureSpendUninstallCost](#)

## FEATURE\_VALUE\_CRITICAL

---

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_VALUE\_CRITICAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)

## FEATURE\_VALUE\_HIGHLYRECOMMENDED

---

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_VALUE\_HIGHLYRECOMMENDED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureGetData](#)

# FEATURE\_VALUE\_STANDARD

**Project** ▪ This information applies to InstallScript projects.

FEATURE\_VALUE\_STANDARD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureGetData](#)

# File Attributes

**Project** ▪ This information applies to InstallScript projects.

**Table 1** ▪ File Attributes

| Attribute           | Description                |
|---------------------|----------------------------|
| FILE_ATTR_NORMAL    | The file is a normal file. |
| FILE_ATTR_ARCHIVED  | The file is archived.      |
| FILE_ATTR_DIRECTORY | The file is a directory.   |
| FILE_ATTR_HIDDEN    | The file is hidden.        |
| FILE_ATTR_READONLY  | The file is read-only.     |
| FILE_ATTR_SYSTEM    | The file is a system file. |

# FILE\_ADD\_FILE

FILE\_ADD\_FILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [SetObjectPermissions](#)

# FILE\_ADD\_SUBDIRECTORY

FILE\_ADD\_SUBDIRECTORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_ALL\_ACCESS

FILE\_ALL\_ACCESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_APPEND\_DATA

FILE\_APPEND\_DATA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_ATTR\_ARCHIVED

FILE\_ATTR\_ARCHIVED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetFileInfo](#)

## FILE\_ATTR\_HIDDEN

FILE\_ATTR\_HIDDEN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetFileInfo](#)

## FILE\_ATTR\_NORMAL

FILE\_ATTR\_NORMAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetFileInfo](#)

## FILE\_ATTR\_READONLY

FILE\_ATTR\_READONLY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetFileInfo](#)

## FILE\_ATTR\_SYSTEM

FILE\_ATTR\_SYSTEM is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetFileInfo](#)

## FILE\_ATTRIBUTE

FILE\_ATTRIBUTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetFileInfo](#)
- [SetFileInfo](#)

## FILE\_BIN\_CUR

FILE\_BIN\_CUR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SeekBytes](#)

## FILE\_BIN\_END

FILE\_BIN\_END is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SeekBytes](#)

## FILE\_BIN\_START

FILE\_BIN\_START is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SeekBytes](#)

## FILE\_DATE

FILE\_DATE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetFileInfo](#)
- [SetFileInfo](#)

## FILE\_DELETE\_CHILD

FILE\_DELETE\_CHILD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_EXECUTE

FILE\_EXECUTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_EXISTS

FILE\_EXISTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Is](#)

## FILE\_INSTALLED

FILE\_INSTALLED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [VerSearchAndUpdateFile](#)

## FILE\_IS\_LOCKED

FILE\_IS\_LOCKED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [VerUpdateFile](#)
- [VerSearchAndUpdateFile](#)

## FILE\_LINE\_LENGTH

FILE\_LINE\_LENGTH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [FileInsertLine](#)
- [FileGrep](#)

## FILE\_LIST\_DIRECTORY

FILE\_LIST\_DIRECTORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_LOCKED

FILE\_LOCKED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Is](#)

## FILE\_MD5\_SIGNATURE

FILE\_MD5\_SIGNATURE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetFileInfo](#)

## FILE\_MODE\_APPEND

FILE\_MODE\_APPEND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [OpenFileMode](#)
- [CreateFile](#)

## FILE\_MODE\_APPEND\_UNICODE

FILE\_MODE\_APPEND\_UNICODE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [OpenFileMode](#)

## FILE\_MODE\_BINARY

FILE\_MODE\_BINARY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [WriteBytes](#)
- [OpenFileMode](#)

## FILE\_MODE\_BINARYREADONLY

FILE\_MODE\_BINARYREADONLY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [OpenFileMode](#)

## FILE\_MODE\_NORMAL

FILE\_MODE\_NORMAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [OpenFileMode](#)

## FILE\_NOT\_FOUND

FILE\_NOT\_FOUND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [VerGetFileVersion](#)
- [FileGrep](#)
- [FileInsertLine](#)
- [FileCompare](#)
- [FileDeleteLine](#)
- [VerFindFileVersion](#)

## FILE\_NO\_VERSION

FILE\_NO\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [VerGetFileVersion](#)
- [VerSearchAndUpdateFile](#)
- [VerFindFileVersion](#)
- [VerUpdateFile](#)

## FILE\_RD\_ONLY

FILE\_RD\_ONLY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [VerUpdateFile](#)
- [FileDeleteLine](#)
- [FileInsertLine](#)
- [VerSearchAndUpdateFile](#)

## FILE\_READ\_ATTRIBUTES

FILE\_READ\_ATTRIBUTES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_READ\_DATA

FILE\_READ\_DATA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_READ\_EA

FILE\_LIST\_DIRECTORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## FILE\_SHARED\_COUNT

---

**Project** • This information applies to InstallScript projects.

FILE\_SHARED\_COUNT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetFileInfo](#)

## FILE\_SIZE

FILE\_SIZE (same as FILE\_SIZE\_LOW) is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetFileInfo](#)

## FILE\_SIZE\_HIGH

FILE\_SIZE\_HIGH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetFileInfo](#)

## FILE\_SIZE\_LOW

FILE\_SIZE\_LOW is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetFileInfo](#)

## FILE\_SRC\_OLD

FILE\_SRC\_OLD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerSearchAndUpdateFile](#)
- [VerUpdateFile](#)

## FILE\_TIME

FILE\_TIME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetFileInfo](#)
- [SetFileInfo](#)

## FILE\_TRAVERSE

FILE\_TRAVERSE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## FILE\_WRITE\_ATTRIBUTES

FILE\_WRITE\_ATTRIBUTES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## FILE\_WRITE\_DATA

FILE\_WRITE\_DATA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## FILE\_WRITE\_EA

FILE\_WRITE\_EA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## FILE\_WRITEABLE

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript Object*

FILE\_WRITEABLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Is](#)

## FILENAME

FILENAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ParsePath](#)

## FILENAME\_ONLY

FILENAME\_ONLY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ParsePath](#)

## FIXED\_DRIVE

FIXED\_DRIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetValidDrivesList](#)

## FONT\_AVAILABLE

FONT\_AVAILABLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Is](#)

## FULL

FULL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [PathAdd](#)
- [PathFind](#)
- [PathMove](#)
- [PathDelete](#)

## FULLSCREEN

FULLSCREEN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [PlaceBitmap](#)

## FULLSCREENSIZE

FULLSCREENSIZE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [PlaceBitmap](#)

## FULLWINDOWMODE

FULLWINDOWMODE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Enable](#)

## FUNCTION\_EXPORTED

---

**Project** - This information applies to InstallScript projects.

FUNCTION\_EXPORTED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Is](#)

## GBYTES

GBYTES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ConvertSizeToUnits](#)
- [StrConvertSizeUnit](#)

## GENERIC\_ALL

GENERIC\_ALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## GENERIC\_EXECUTE

GENERIC\_EXECUTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## GENERIC\_READ

GENERIC\_READ is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## GENERIC\_WRITE

GENERIC\_WRITE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## GREATER\_THAN

GREATER\_THAN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FileCompare](#)
- [VerCompare](#)

## GREEN

GREEN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetColor](#)
- [SetTitle](#)

## GTFIS\_OPTION\_DELETE\_TEMP\_FILE

GTFIS\_OPTION\_DELETE\_TEMP\_FILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetTempFileNameIS](#)

## GTFIS\_OPTION\_DONT\_CREATE\_DIR

GTFIS\_OPTION\_DONT\_CREATE\_DIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetTempFileNameIS](#)

## GTFIS\_OPTION\_DONT\_RESOLVE\_TEXTSUBS

GTFIS\_OPTION\_DONT\_RESOLVE\_TEXTSUBS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetTempFileNameIS](#)

## GTFIS\_OPTION\_NONE

GTFIS\_OPTION\_NONE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetTempFileNameIS](#)

## HELP

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

HELP is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Do](#)
- [HandlerEx](#)

## HIDE\_DISABLED\_BTNS

HIDE\_DISABLED\_BTNS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

The HIDE\_DISABLED\_BTNS constant indicates that the per-user and all-users options should be hidden instead of being disabled. The default value of this variable is TRUE. Note that when this variable is set to TRUE, both options are hidden if either option is determined to be disabled.

### Used With

- [SdCustomerInformation](#)
- [SdCustomerInformationEx](#)

## HKEY\_CLASSES\_ROOT

HKEY\_CLASSES\_ROOT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBSetDefaultRoot](#)

- [RegDBSetKeyValueEx](#)
- [RegDBDeleteKey](#)
- [RegDBDeleteValue](#)
- [RegDBGetKeyValueEx](#)
- [RegDBKeyExist](#)
- [RegDBCreateKeyEx](#)

## HKEY\_CURRENT\_USER

HKEY\_CURRENT\_USER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBSetDefaultRoot](#)

## HKEY\_LOCAL\_MACHINE

HKEY\_LOCAL\_MACHINE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

---

**Note** ▪ Windows NT 4.0 does not allow the creation of a key directly under HKEY\_LOCAL\_MACHINE.

### Used With

- [RegDBConnectRegistry](#)
- [InstallationInfo](#)
- [RegDBSetDefaultRoot](#)

## HKEY\_USERS

HKEY\_USERS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

---

**Note** ▪ Windows NT 4.0 does not allow the creation of a key directly under HKEY\_USERS.

### Used With

- [RegDBSetDefaultRoot](#)
- [RegDBConnectRegistry](#)

# HKEY\_USER\_SELECTABLE

**Project** ▪ This information applies to InstallScript projects.

HKEY\_USER\_SELECTABLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBSetDefaultRoot](#)

# HOURGLASS

HOURGLASS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [Disable](#)
- [Enable](#)

# HWND\_DESKTOP

HWND\_DESKTOP is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetWindowHandle](#)

# HWND\_INSTALL

HWND\_INSTALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetWindowHandle](#)

# IDCANCEL

**Project** ▪ This information applies to InstallScript projects.

IDCANCEL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDir](#)
- [SelectDirEx](#)

## IDOK

**Project** ▪ This information applies to InstallScript projects.

IDOK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SelectDir](#)
- [SelectDirEx](#)

## IDS\_IFX\_ERROR\_INVALID\_MEDIA\_PASSWORD

**Project** ▪ This information applies to InstallScript projects.

IDS\_IFX\_ERROR\_INVALID\_MEDIA\_PASSWORD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SdLoadString](#)

## IFX\_ONNEXTDISK\_PACKAGE\_CAPTION

**Project** ▪ This information applies to InstallScript projects.

IFX\_ONNEXTDISK\_PACKAGE\_CAPTION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SdLoadString](#)

# IFX\_ONNEXTDISK\_PACKAGE\_MSG

**Project** ▪ This information applies to InstallScript projects.

IFX\_ONNEXTDISK\_PACKAGE\_MSG is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- [SdLoadString](#)

# INCLUDE\_SUBDIR

INCLUDE\_SUBDIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FindAllDirs](#)
- [XCopyFile](#)

# INDVFILESTATUS

INDVFILESTATUS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [Disable](#)
- [SetStatusWindow](#)
- [Enable](#)

# INFORMATION

INFORMATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [MessageBox](#)
- [SprintfBox](#)

## IS\_PERMISSIONS\_OPTION\_64BIT\_OBJECT

IS\_PERMISSIONS\_OPTION\_64BIT\_OBJECT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## IS\_PERMISSIONS\_OPTION\_ALLOW\_ACCESS

IS\_PERMISSIONS\_OPTION\_ALLOW\_ACCESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## IS\_PERMISSIONS\_OPTION\_DENY\_ACCESS

IS\_PERMISSIONS\_OPTION\_DENY\_ACCESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## IS\_PERMISSIONS\_OPTION\_NO\_APPLYDOWN

IS\_PERMISSIONS\_OPTION\_NO\_APPLYDOWN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## IS\_PERMISSIONS\_TYPE\_FILE

IS\_PERMISSIONS\_TYPE\_FILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## IS\_PERMISSIONS\_TYPE\_FOLDER

IS\_PERMISSIONS\_TYPE\_FOLDER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## IS\_PERMISSIONS\_TYPE\_REGISTRY

IS\_PERMISSIONS\_TYPE\_REGISTRY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## ISDIFX\_OPTION\_DONT\_ASSOCIATE

ISDIFX\_OPTION\_DONT\_ASSOCIATE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackageUninstall](#)

## ISDIFX\_OPTION\_DONT\_RESOLVE\_TEXTSUBS

ISDIFX\_OPTION\_DONT\_RESOLVE\_TEXTSUBS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DIFxDriverPackageGetPath](#)
- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackagePreinstall](#)
- [DIFxDriverPackageUninstall](#)

## ISDIFX\_OPTION\_LOG\_IN\_DRIVER\_PACKAGE\_PATH

ISDIFX\_OPTION\_LOG\_IN\_DRIVER\_PACKAGE\_PATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackagePreinstall](#)

## ISDIFX\_OPTION\_NO\_REPAIR

ISDIFX\_OPTION\_NO\_REPAIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [DIFxDriverPackageInstall](#)
- [DIFxDriverPackagePreinstall](#)

## ISERR\_GEN\_FAILURE

**Project** ▪ This information applies to InstallScript projects.

ISERR\_GEN\_FAILURE is a predefined constant that is used to represent the value that is returned by built-in functions when they fail and more specific information on the cause of the failure is not available. You cannot change the value of a predefined constant.

## ISERR\_SUCCESS

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

ISERR\_SUCCESS is a predefined constant that is used to represent the value that is returned by built-in functions when they are successful. You cannot change the value of a predefined constant.

## ISLANG\_AFRIKAANS

ISLANG\_AFRIKAANS is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_AFRIKAANS\_STANDARD

ISLANG\_AFRIKAANS\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ALBANIAN

ISLANG\_ALBANIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ALBANIAN\_STANDARD

ISLANG\_ALBANIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ALL

ISLANG\_ALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterLanguage](#)

## ISLANG\_ARABIC

ISLANG\_ARABIC is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_ALGERIA

ISLANG\_ARABIC\_ALGERIA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_BAHRAIN

ISLANG\_ARABIC\_BAHRAIN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_EGYPT

ISLANG\_ARABIC\_EGYPT is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_IRAQ

ISLANG\_ARABIC\_IRAQ is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_JORDAN

ISLANG\_ARABIC\_JORDAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_KUWAIT

ISLANG\_ARABIC\_KUWAIT is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_LEBANON

ISLANG\_ARABIC\_LEBANON is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_LIBYA

ISLANG\_ARABIC\_LIBYA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_MOROCCO

ISLANG\_ARABIC\_MOROCCO is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_OMAN

ISLANG\_ARABIC\_OMAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_QATAR

ISLANG\_ARABIC\_QATAR is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_SAUDIARABIA

ISLANG\_ARABIC\_SAUDIARABIA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_SYRIA

ISLANG\_ARABIC\_SYRIA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_TUNISIA

ISLANG\_ARABIC\_TUNISIA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_UAE

ISLANG\_ARABIC\_UAE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ARABIC\_YEMEN

ISLANG\_ARABIC\_YEMEN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_BASQUE

ISLANG\_BASQUE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_BASQUE\_STANDARD

ISLANG\_BASQUE\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_BELARUSIAN

ISLANG\_BELARUSIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_BELARUSIAN\_STANDARD

ISLANG\_BELARUSIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_BULGARIAN

ISLANG\_BULGARIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_BULGARIAN\_STANDARD

ISLANG\_BULGARIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CATALAN

ISLANG\_CATALAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CATALAN\_STANDARD

ISLANG\_CATALAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CHINESE

ISLANG\_CHINESE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CHINESE\_HONGKONG

ISLANG\_CHINESE\_HONGKONG is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CHINESE\_PRC

ISLANG\_CHINESE\_PRC is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CHINESE\_SINGAPORE

ISLANG\_CHINESE\_SINGAPORE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CHINESE\_TAIWAN

ISLANG\_CHINESE\_TAIWAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CROATIAN

ISLANG\_CROATIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CROATIAN\_STANDARD

ISLANG\_CROATIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CZECH

ISLANG\_CZECH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_CZECH\_STANDARD

ISLANG\_CZECH\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_DANISH

ISLANG\_DANISH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_DANISH\_STANDARD

ISLANG\_DANISH\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_DUTCH

ISLANG\_DUTCH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_DUTCH\_BELGIAN

ISLANG\_DUTCH\_BELGIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_DUTCH\_STANDARD

ISLANG\_DUTCH\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH

ISLANG\_ENGLISH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_AUSTRALIAN

ISLANG\_ENGLISH\_AUSTRALIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_BELIZE

ISLANG\_ENGLISH\_BELIZE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_CANADIAN

ISLANG\_ENGLISH\_CANADIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_CARIBBEAN

ISLANG\_ENGLISH\_CARIBBEAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_IRELAND

ISLANG\_ENGLISH\_IRELAND is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_JAMAICA

ISLANG\_ENGLISH\_JAMAICA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_NEWZEALAND

ISLANG\_ENGLISH\_NEWZEALAND is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_SOUTHAFRICA

ISLANG\_ENGLISH\_SOUTHAFRICA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_TRINIDAD

ISLANG\_ENGLISH\_TRINIDAD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_UNITEDKINGDOM

ISLANG\_ENGLISH\_UNITEDKINGDOM is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ENGLISH\_UNITEDSTATES

ISLANG\_ENGLISH\_UNITEDSTATES is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ESTONIAN

ISLANG\_ESTONIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ESTONIAN\_STANDARD

ISLANG\_ESTONIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FAEROESE

ISLANG\_FAEROESE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FAEROESE\_STANDARD

ISLANG\_FAEROESE\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FARSI

ISLANG\_FARSI is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FARSI\_STANDARD

ISLANG\_FARSI\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FINNISH

ISLANG\_FINNISH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FINNISH\_STANDARD

ISLANG\_FINNISH\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FRENCH

ISLANG\_FRENCH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FRENCH\_BELGIAN

ISLANG\_FRENCH\_BELGIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FRENCH\_CANADIAN

ISLANG\_FRENCH\_CANADIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FRENCH\_LUXEMBOURG

ISLANG\_FRENCH\_LUXEMBOURG is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FRENCH\_STANDARD

ISLANG\_FRENCH\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_FRENCH\_SWISS

ISLANG\_FRENCH\_SWISS is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_GERMAN

ISLANG\_GERMAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_GERMAN\_AUSTRIAN

ISLANG\_GERMAN\_AUSTRIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_GERMAN\_LIECHTENSTEIN

ISLANG\_GERMAN\_LIECHTENSTEIN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_GERMAN\_LUXEMBOURG

ISLANG\_GERMAN\_LUXEMBOURG is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_GERMAN\_STANDARD

ISLANG\_GERMAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_GERMAN\_SWISS

ISLANG\_GERMAN\_SWISS is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_GREEK

ISLANG\_GREEK is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_GREEK\_STANDARD

ISLANG\_GREEK\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_HEBREW

ISLANG\_HEBREW is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_HEBREW\_STANDARD

ISLANG\_HEBREW\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_HUNGARIAN

ISLANG\_HUNGARIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_HUNGARIAN\_STANDARD

ISLANG\_HUNGARIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ICELANDIC

ISLANG\_ICELANDIC is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ICELANDIC\_STANDARD

ISLANG\_ICELANDIC\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_INDONESIAN

ISLANG\_INDONESIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_INDONESIAN\_STANDARD

ISLANG\_INDONESIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ITALIAN

ISLANG\_ITALIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ITALIAN\_STANDARD

ISLANG\_ITALIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ITALIAN\_SWISS

ISLANG\_ITALIAN\_SWISS is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_JAPANESE

ISLANG\_JAPANESE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_JAPANESE\_STANDARD

ISLANG\_JAPANESE\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_KOREAN

ISLANG\_KOREAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_KOREAN\_JOHAB

ISLANG\_KOREAN\_JOHAB is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_KOREAN\_STANDARD

ISLANG\_KOREAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_LATVIAN

ISLANG\_LATVIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_LATVIAN\_STANDARD

ISLANG\_LATVIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_LITHUANIAN

ISLANG\_LITHUANIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_LITHUANIAN\_STANDARD

ISLANG\_LITHUANIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_NORWEGIAN

ISLANG\_NORWEGIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_NORWEGIAN\_BOKMAL

ISLANG\_NORWEGIAN\_BOKMAL is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_NORWEGIAN\_NYNORSK

ISLANG\_NORWEGIAN\_NYNORSK is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_POLISH

ISLANG\_POLISH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_POLISH\_STANDARD

ISLANG\_POLISH\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_PORTUGUESE

ISLANG\_PORTUGUESE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_PORTUGUESE\_BRAZILIAN

ISLANG\_PORTUGUESE\_BRAZILIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_PORTUGUESE\_STANDARD

ISLANG\_PORTUGUESE\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ROMANIAN

ISLANG\_ROMANIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_ROMANIAN\_STANDARD

ISLANG\_ROMANIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_RUSSIAN

ISLANG\_RUSSIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_RUSSIAN\_STANDARD

ISLANG\_RUSSIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SERBIAN\_CYRILLIC

ISLANG\_SERBIAN\_CYRILLIC is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SERBIAN\_LATIN

ISLANG\_SERBIAN\_LATIN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SLOVAK

ISLANG\_SLOVAK is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SLOVAK\_STANDARD

ISLANG\_SLOVAK\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SLOVENIAN

ISLANG\_SLOVENIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SLOVENIAN\_STANDARD

ISLANG\_SLOVENIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH

ISLANG\_SPANISH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_ARGENTINA

ISLANG\_SPANISH\_ARGENTINA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_BOLIVIA

ISLANG\_SPANISH\_BOLIVIA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_CHILE

ISLANG\_SPANISH\_CHILE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_COLOMBIA

ISLANG\_SPANISH\_COLOMBIA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_COSTARICA

ISLANG\_SPANISH\_COSTARICA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_DOMINICANREPUBLIC

ISLANG\_SPANISH\_DOMINICANREPUBLIC is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_ECUADOR

ISLANG\_SPANISH\_ECUADOR is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_ELSALVADOR

ISLANG\_SPANISH\_ELSALVADOR is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_GUATEMALA

ISLANG\_SPANISH\_GUATEMALA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_HONDURAS

ISLANG\_SPANISH\_HONDURAS is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_MEXICAN

ISLANG\_SPANISH\_MEXICAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_MODERNSORT

ISLANG\_SPANISH\_MODERNSORT is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_NICARAGUA

ISLANG\_SPANISH\_NICARAGUA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_PANAMA

ISLANG\_SPANISH\_PANAMA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_PARAGUAY

ISLANG\_SPANISH\_PARAGUAY is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_PERU

ISLANG\_SPANISH\_PERU is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_PUERTORICO

ISLANG\_SPANISH\_PUERTORICO is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_TRADITIONALSORT

ISLANG\_SPANISH\_TRADITIONALSORT is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_URUGUAY

ISLANG\_SPANISH\_URUGUAY is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SPANISH\_VENEZUELA

ISLANG\_SPANISH\_VENEZUELA is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SWEDISH

ISLANG\_SWEDISH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SWEDISH\_FINLAND

ISLANG\_SWEDISH\_FINLAND is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_SWEDISH\_STANDARD

ISLANG\_SWEDISH\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_THAI

ISLANG\_THAI is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_THAI\_STANDARD

ISLANG\_THAI\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_TURKISH

ISLANG\_TURKISH is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_TURKISH\_STANDARD

ISLANG\_TURKISH\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_UKRAINIAN

ISLANG\_UKRAINIAN is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_UKRAINIAN\_STANDARD

ISLANG\_UKRAINIAN\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_VIETNAMESE

ISLANG\_VIETNAMESE is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISLANG\_VIETNAMESE\_STANDARD

ISLANG\_VIETNAMESE\_STANDARD is a predefined constant that corresponds to a Windows language ID. For more information about how to use this constant, see [Language IDs](#).

## ISOSL\_ALL

ISOSL\_ALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_SUPPORTED

ISOSL\_SUPPORTED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WIN7\_SERVER2008R2

ISOSL\_WIN7\_SERVER2008R2 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WIN8

ISOSL\_WIN8 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WIN81

ISOSL\_WIN81 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WIN10

ISOSL\_WIN10 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WIN10\_SERVER2019

ISOSL\_WIN10\_SERVER2019 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WIN10\_SERVER2019

ISOSL\_WIN10\_SERVER2019 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WIN11

ISOSL\_WIN11 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WIN10\_SERVER2022

ISOSL\_WIN10\_SERVER2022 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WINVISTA

---

**Note** • [ISOSL\\_WINVISTA\\_SERVER2008](#) *supersedes* ISOSL\_WINVISTA.

ISOSL\_WINVISTA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WINVISTA\_SERVER2008

ISOSL\_WINVISTA\_SERVER2008 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOSL\_WINXP

ISOSL\_WINXP is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_ALL

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_ALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_BACKOFFICE

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_BACKOFFICE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_DATACENTER

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_DATACENTER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_ENTERPRISE

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_ENTERPRISE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

## ISOS\_ST\_PROC\_ARCH\_32

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_PROC\_ARCH\_32 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOS\_ST\_PROC\_ARCH\_AMD64

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_PROC\_ARCH\_AMD64 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOS\_ST\_PROC\_ARCH\_IA64

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_PROC\_ARCH\_IA64 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

## ISOS\_ST\_SERVER

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_SERVER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_SERVER2003\_R2

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_SERVER2003\_R2 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_SMALLBUSINESS

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_SMALLBUSINESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_SMALLBUSINESS\_RESTRICTED

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_SMALLBUSINESS\_RESTRICTED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_TERMINAL

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_TERMINAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_WORKSTATION

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_WORKSTATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_XP\_HOME

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_XP\_HOME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISOS\_ST\_XP\_PRO

**Project** ▪ This information applies to InstallScript projects.

ISOS\_ST\_XP\_PRO is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [FeatureFilterOS](#)

# ISUS\_AGENT\_FEATURE

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## ISUS\_MAIN\_FEATURE

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## ISUS\_TEXTSUB\_HOST

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## ISUS\_TEXTSUB\_INTERVAL

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## ISUS\_TEXTSUB\_LANGUAGE

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## ISUS\_TEXTSUB\_LOGO

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## ISUS\_TEXTSUB\_MANAGER

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## ISUS\_TEXTSUB\_VERSION

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## ISUS\_UPDATEMANAGER\_FEATURE

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## IS\_386

IS\_386 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_486

IS\_486 is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_ALPHA

IS\_ALPHA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_CDROM

IS\_CDROM is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_EGA

IS\_EGA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_FIXED

IS\_FIXED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_FOLDER

IS\_FOLDER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [QueryProgItem](#)
- [ReplaceFolderIcon](#)

## IS\_ITEM

IS\_ITEM is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [QueryProgItem](#)
- [ReplaceFolderIcon](#)

## IS\_PENTIUM

IS\_PENTIUM is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_REMOTE

IS\_REMOTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_REMOVABLE

IS\_REMOVABLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_SVGA

IS\_SVGA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_UNKNOWN

IS\_UNKNOWN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_UVGA

IS\_UVGA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_VGA

IS\_VGA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_WINDOWS

IS\_WINDOWS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_WINDOWS9X

IS\_WINDOWS9X is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_WINDOWSNT

IS\_WINDOWSNT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## IS\_XVGA

IS\_XVGA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## KBYTES

KBYTES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ConvertSizeToUnits](#)
- [StrConvertSizeUnit](#)

## KEY\_CREATE\_LINK

KEY\_CREATE\_LINK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## KEY\_CREATE\_SUB\_KEY

KEY\_CREATE\_SUB\_KEY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## KEY\_ENUMERATE\_SUB\_KEYS

KEY\_ENUMERATE\_SUB\_KEYS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## KEY\_NOTIFY

GENERIC\_WRITE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## KEY\_QUERY\_VALUE

KEY\_QUERY\_VALUE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## KEY\_SET\_VALUE

KEY\_SET\_VALUE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetObjectPermissions](#)

## LAAW\_OPTION\_CHANGEDIRECTORY

LAAW\_OPTION\_CHANGEDIRECTORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [LaunchApplication](#)

## LAAW\_OPTION\_FIXUP\_PROGRAM

LAAW\_OPTION\_CHANGEDIRECTORY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [LaunchApplication](#)

## LAAW\_OPTION\_HIDDEN

LAAW\_OPTION\_HIDDEN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)
- [LaunchAppAndWait](#)
- [LaunchApplication](#)
- [WaitForApplication](#)

## LAAW\_OPTION\_MAXIMIZED

LAAW\_OPTION\_MAXIMIZED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)
- [LaunchAppAndWait](#)
- [LaunchApplication](#)
- [WaitForApplication](#)

## LAAW\_OPTION\_MINIMIZED

LAAW\_OPTION\_MINIMIZED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)
- [LaunchAppAndWait](#)
- [LaunchApplication](#)

- [WaitForApplication](#)

## LAAW\_OPTION\_NO\_CHANGEDIRECTORY

LAAW\_OPTION\_NO\_CHANGEDIRECTORY is an obsolete predefined constant.

## LAAW\_OPTION\_NOWAIT

LAAW\_OPTION\_NOWAIT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)
- [LaunchAppAndWait](#)
- [LaunchApplication](#)
- [WaitForApplication](#)

## LAAW\_OPTION\_SET\_BATCH\_INSTALL

**Project** ▪ This constant is available for InstallScript event-driven code in InstallScript and InstallScript MSI projects. It does not have any effect in InstallScript custom actions in Basic MSI, InstallScript MSI, or Suite/Advanced UI projects.

LAAW\_OPTION\_SET\_BATCH\_INSTALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)
- [LaunchAppAndWait](#)
- [LaunchApplication](#)
- [WaitForApplication](#)

## LAAW\_OPTION\_SHOW\_HOURLASS

LAAW\_OPTION\_SHOW\_HOURLASS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)

- [LaunchAppAndWait](#)

## LAAW\_OPTION\_USE\_CALLBACK

LAAW\_OPTION\_USE\_CALLBACK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)
- [LaunchAppAndWait](#)
- [LaunchApplication](#)
- [WaitForApplication](#)

## LAAW\_OPTION\_USE\_SHELLEXECUTE

LAAW\_OPTION\_USE\_SHELLEXECUTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [LaunchApplication](#)

## LAAW\_OPTION\_WAIT

LAAW\_OPTION\_WAIT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)
- [LaunchAppAndWait](#)
- [LaunchApplication](#)
- [WaitForApplication](#)

## LAAW\_OPTION\_WAIT\_INCL\_CHILD

LAAW\_OPTION\_WAIT\_INCL\_CHILD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DoInstall](#)
- [LaunchAppAndWait](#)

- [LaunchApplication](#)
- [WaitForApplication](#)

## LANGUAGE\_SUPPORTED

LANGUAGE\_SUPPORTED is a predefined constant that is used to specify the language that an installation supports. The language is a four-digit hexadecimal language code, including the 0x prefix. For example, for English, the value should be 0x0409. To build a string with STANDARD\_SELECTED\_LANGUAGE in this format, use a statement such as:

```
Sprintf (szLang, "0x%.04lx", STANDARD_SELECTED_LANGUAGE);
```

You cannot change the value of a predefined constant.

### Used With

- [Is](#)

## LANGUAGE

LANGUAGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## LESS\_THAN

LESS\_THAN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FileCompare](#)
- [VerCompare](#)

## LINE\_NUMBER

LINE\_NUMBER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FileDeleteLine](#)
- [FileInsertLine](#)

## LISTBOX\_ENTER

LISTBOX\_ENTER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CtrlGetSubCommand](#)

## LISTBOX\_SELECT

LISTBOX\_SELECT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [CtrlGetSubCommand](#)

## LISTFIRST

LISTFIRST is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ListSetIndex](#)

## LISTLAST

LISTLAST is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ListSetIndex](#)

## LISTNEXT

LISTNEXT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ListSetIndex](#)

## LISTPREV

LISTPREV is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ListSetIndex](#)

## LIST\_NULL

LIST\_NULL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ListCreate](#)

## LOCKEDFILE

LOCKEDFILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [XCopyFile](#)
- [InstallationInfo](#)
- [VerUpdateFile](#)
- [DeinstallStart](#)

## LOGGING

LOGGING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DeinstallStart](#)
- [Disable](#)
- [Enable](#)
- [InstallationInfo](#)

## LOWER\_LEFT

LOWER\_LEFT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceBitmap](#)
- [PlaceWindow](#)

## LOWER\_RIGHT

LOWER\_RIGHT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceBitmap](#)
- [PlaceWindow](#)

## LWTF\_OPTION\_APPEND\_TO\_FILE

LWTF\_OPTION\_APPEND\_TO\_FILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ListWriteToFileEx](#)

## LWTF\_OPTION\_WRITE\_AS\_ANSI

LWTF\_OPTION\_WRITE\_AS\_ANSI is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

---

**Note** ▪ In earlier versions of InstallShield, this constant was called `LWFT_OPTION_WRITE_AS_ANSI` (where **LWFT** was used instead of **LWTF**). To maintain backwards compatibility, both constants are now available, and they are defined the same way.

### Used With

- [ListWriteToFileEx](#)

## LWTF\_OPTION\_WRITE\_AS\_UNICODE

LWTF\_OPTION\_WRITE\_AS\_UNICODE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Note** ▪ In earlier versions of InstallShield, this constant was called `LWFT_OPTION_WRITE_AS_UNICODE` (where **LWFT** was used instead of **LWTF**). To maintain backwards compatibility, both constants are now available, and they are defined the same way.

### Used With

- [ListWriteToFileEx](#)

## MAGENTA

MAGENTA is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetColor](#)
- [SetTitle](#)

## MATH\_COPROCESSOR

MATH\_COPROCESSOR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Is](#)

## MBYTES

MBYTES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ConvertSizeToUnits](#)
- [StrConvertSizeUnit](#)

## MEDIA\_FIELD\_ADDREMOVE\_NOMODIFY

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_ADDREMOVE\_NOMODIFY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_ADDREMOVE\_NOREMOVE

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_ADDREMOVE\_NOREMOVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_COMPANY\_NAME

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_COMPANY\_NAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FIELD\_MEDIA\_FLAGS

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_MEDIA\_FLAGS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FIELD\_PREVIOUS\_VERSIONS

---

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PREVIOUS\_VERSIONS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FIELD\_PRODUCT\_COMMENTS

---

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_COMMENTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_PRODUCT\_EXE

---

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_EXE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FIELD\_PRODUCT\_ICON

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_ICON is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_PRODUCT\_NAME

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_NAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FIELD\_PRODUCT\_README

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_README is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_PRODUCT\_SUPPORT\_CONTACT

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_SUPPORT\_CONTACT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_PRODUCT\_SUPPORT\_PHONE

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_SUPPORT\_PHONE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_PRODUCT\_SUPPORT\_URL

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_SUPPORT\_URL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_PRODUCT\_UPDATE\_URL

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_UPDATE\_URL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_PRODUCT\_URL

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_URL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_FIELD\_PRODUCT\_VERSION

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_PRODUCT\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FIELD\_TARGETDIR

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FIELD\_TARGETDIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FLAG\_FORMAT\_DIFFERENTIAL

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FLAG\_FORMAT\_DIFFERENTIAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FLAG\_FORMAT\_PATCH

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FLAG\_FORMAT\_PATCH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MediaGetData](#)

## MEDIA\_FLAG\_UPDATEMODE\_SUPPORTED

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_FLAG\_UPDATEMODE\_SUPPORTED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

The MEDIA\_FLAG\_UPDATEMODE\_SUPPORTED flag is always set.

### Used With

- [MediaGetData](#)
- [MediaGetDataEx](#)

## MEDIA\_PASSWORD\_KEY

**Project** ▪ This information applies to InstallScript projects.

MEDIA\_PASSWORD\_KEY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [LogReadCustomString](#)
- [LogWriteCustomString](#)

# METAFILE

METAFILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [SizeWindow](#)

# MMEDIA\_AVI

MMEDIA\_AVI is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [PlayMMedia](#)
- [PlaceWindow](#)
- [SizeWindow](#)

# MMEDIA\_MIDI

MMEDIA\_MIDI is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [PlayMMedia](#)

# MMEDIA\_PLAYASYNCH

MMEDIA\_PLAYASYNCH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [PlayMMedia](#)

# MMEDIA\_PLAYCONTINUOUS

MMEDIA\_PLAYCONTINUOUS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [PlayMMedia](#)

## MMEDIA\_PLAYSYNCH

MMEDIA\_PLAYSYNCH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlayMMedia](#)

## MMEDIA\_STOP

MMEDIA\_STOP is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlayMMedia](#)

## MMEDIA\_SWF

MMEDIA\_SWF is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlayMMedia](#)
- [PlaceWindow](#)
- [SizeWindow](#)

## MMEDIA\_WAVE

MMEDIA\_WAVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlayMMedia](#)

## MODIFY

---

**Project** ▪ This information applies to InstallScript projects.

MODIFY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SdWelcomeMaint](#)

## NEXT

NEXT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [AskDestPath](#)
- [AskOptions](#)
- [AskPath](#)
- [AskText](#)
- [FeatureDialog](#)
- [SdAskDestPath](#)
- [SdAskOptions](#)
- [SdAskOptionsList](#)
- [SdBitmap](#)
- [SdDisplayTopics](#)
- [SdFeatureDialog](#)
- [SdFeatureDialog2](#)
- [SdFeatureDialogAdv](#)
- [SdFeatureMult](#)
- [SdLicense](#)
- [SdOptionsButtons](#)
- [SdRegisterUser](#)
- [SdRegisterUserEx](#)
- [SdSelectFolder](#)
- [SdShowAnyDialog](#)
- [SdShowDlgEdit1](#)
- [SdShowDlgEdit2](#)
- [SdShowDlgEdit3](#)
- [SdShowFileMods](#)
- [SdShowInfoList](#)

- [SdStartCopy](#)
- [SdWelcome](#)
- [SelectFolder](#)
- [Welcome](#)

## NEXTBUTTON

NEXTBUTTON is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Disable](#)
- [Enable](#)
- [Is](#)

## NO

NO is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SdConfirmNewDir](#)
- [SdConfirmRegistration](#)
- [AskYesNo](#)

## NONEXCLUSIVE

NONEXCLUSIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SdAskOptionsList](#)
- [AskOptions](#)
- [SdAskOptions](#)

## NORMALMODE

NORMALMODE is a predefined constant that can be used to test whether or not a setup is running in silent mode. For more information, refer to the InstallShield system variable [MODE](#).

# NORMAL\_PRIORITY\_CLASS

**Project** ▪ This information applies to InstallScript projects.

NORMAL\_PRIORITY\_CLASS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- SERVICE\_IS\_PARAMS

# NOSET

NOSET is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- EzBatchAddString

# NOTEXISTS

NOTEXISTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- ExistsDir
- ExistsDisk

# NO\_SUBDIR

**Project** ▪ This information applies to InstallScript projects.

NO\_SUBDIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- FeatureFileEnum

# NULL

NULL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [AddFolderIcon](#)
- [CreateShortcut](#)
- [GetShortcutInfo](#)
- [FindWindow](#)
- [QueryProgItem](#)
- [ReplaceFolderIcon](#)
- [ReplaceShortcut](#)

# NUMBERLIST

NUMBERLIST is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [ListCreate](#)

# OFF

OFF is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [StatusUpdate](#)

# OK

OK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [EnterDisk](#)

## ON

ON is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [StatusUpdate](#)

## ONLYDIR

ONLYDIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [DeleteDir](#)

## OTHER\_FAILURE

OTHER\_FAILURE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FileDeleteLine](#)
- [VerUpdateFile](#)
- [FileCompare](#)
- [FileGrep](#)
- [FileInsertLine](#)

## OUT\_OF\_DISK\_SPACE

OUT\_OF\_DISK\_SPACE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerUpdateFile](#)
- [FileInsertLine](#)
- [FileDeleteLine](#)
- [VerSearchAndUpdateFile](#)

# PARALLEL

PARALLEL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetSystemInfo](#)

# PARTIAL

PARTIAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [PathAdd](#)
- [PathFind](#)
- [PathMove](#)
- [PathDelete](#)

# PATH

PATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [ParsePath](#)

# PATH\_EXISTS

» InstallScript Language Reference

PATH\_EXISTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [Is](#)

# PCRESTORE

---

**Project** • This information applies to InstallScript projects.

PCRESTORE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Disable](#)
- [Enable](#)

## PERSONAL

PERSONAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ProgDefGroupType](#)

## READ\_CONTROL

READ\_CONTROL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_PARAMS](#)
- [SetObjectPermissions](#)

## REBOOTED

REBOOTED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Is](#)

## RECORDMODE

RECORDMODE is a predefined constant that can be used to test whether or not a setup is automatically generating a silent setup file (.iss file), which is a record of the setup input, in the Windows folder. For more information, refer to the InstallScript system variable [MODE](#).

# RED

RED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [SetColor](#)
- [SetTitle](#)

# REGDBREMOTEREGCONNECTED

REGDBREMOTEREGCONNECTED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [Is](#)

# REGDB\_APPPATH

REGDB\_APPPATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_APPPATH\_DEFAULT

REGDB\_APPPATH\_DEFAULT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_BINARY

REGDB\_BINARY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBSetAppInfo](#)
- [RegDBGetKeyValueEx](#)
- [RegDBSetKeyValueEx](#)
- [RegDBGetAppInfo](#)
- [RegDBSetKeyValueEx](#)

## REGDB\_ERR\_CONNECTIONEXISTS

REGDB\_ERR\_CONNECTIONEXISTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBConnectRegistry](#)

## REGDB\_ERR\_CORRUPTEDREGISTRY

REGDB\_ERR\_CORRUPTEDREGISTRY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBConnectRegistry](#)

## REGDB\_ERR\_INITIALIZATION

REGDB\_ERR\_INITIALIZATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBConnectRegistry](#)

## REGDB\_ERR\_INVALIDHANDLE

REGDB\_ERR\_INVALIDHANDLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBConnectRegistry](#)

## REGDB\_ERR\_INVALIDNAME

REGDB\_ERR\_INVALIDNAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `RegDBConnectRegistry`

## REGDB\_KEYPATH\_APPPATHS

REGDB\_KEYPATH\_APPPATHS is a predefined constant whose value is the registry location (not including the root key) of the general application paths key, that is, `Software\Microsoft\Windows\CurrentVersion\App Paths\`. You can use this constant to specify a key when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_KEYPATH\_DOTNET\_10

REGDB\_KEYPATH\_DOTNET\_10 is a predefined constant whose value is the registry location (not including the root key) of the registry key for version 1.0 of the .NET Framework. It is defined as follows:

```
Software\Microsoft\NET Framework Setup\Full\v1.0.3705\1033\Microsoft .NET Framework Full v1.0.3705
(1033)\
```

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- `Is`

## REGDB\_KEYPATH\_DOTNET\_11

REGDB\_KEYPATH\_DOTNET\_11 is a predefined constant whose value is the registry location (not including the root key) of the registry key for version 1.1 of the .NET Framework. It is defined as follows:

```
Software\Microsoft\NET Framework Setup\NDP\v1.1.4322\
```

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- `Is`

## REGDB\_KEYPATH\_DOTNET\_20

REGDB\_KEYPATH\_DOTNET\_20 is a predefined constant whose value is the registry location (not including the root key) of the registry key for version 2.0 of the .NET Framework. It is defined as follows:

Software\Microsoft\NET Framework Setup\NDP\v2.0.50215\

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- **Is**

## REGDB\_KEYPATH\_DOTNET\_30

REGDB\_KEYPATH\_DOTNET\_30 is a predefined constant whose value is the registry location (not including the root key) of the registry key for the RTM version of the .NET Framework 3.0. It is defined as follows:

Software\Microsoft\NET Framework Setup\NDP\v3.0\Setup\

**Tip** • You can use the `REGDB_KEYPATH_DOTNET_30` variable to detect whether the RTM version of the .NET Framework 3.0 is installed. To detect whether SP1—or a later service pack—of the .NET Framework 3.0 is installed, use `REGDB_KEYPATH_DOTNET_30_SP`.

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- **Is**

## REGDB\_KEYPATH\_DOTNET\_30\_SP

REGDB\_KEYPATH\_DOTNET\_30\_SP is a predefined constant whose value is the registry location (not including the root key) of the registry key for SP1—or a later service pack—of the .NET Framework 3.0. It is defined as follows:

Software\Microsoft\NET Framework Setup\NDP\v3.0\

**Tip** • You can use the `REGDB_KEYPATH_DOTNET_30_SP` variable when querying whether SP1—or a later service pack—of the .NET Framework 3.0 is installed. To detect whether the RTM version of the .NET Framework 3.0 is installed, use `REGDB_KEYPATH_DOTNET_30`.

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- **Is**

## REGDB\_KEYPATH\_DOTNET\_35

REGDB\_KEYPATH\_DOTNET\_35 is a predefined constant whose value is the registry location (not including the root key) of the registry key for version 3.5 of the .NET Framework. It is defined as follows:

`Software\Microsoft\NET Framework Setup\NDP\v3.5\`

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- **Is**

## REGDB\_KEYPATH\_DOTNET\_40\_CLIENT

REGDB\_KEYPATH\_DOTNET\_40\_CLIENT is a predefined constant whose value is the registry location (not including the root key) of the registry key for version 4.0 of the .NET Framework Client Profile. It is defined as follows:

`Software\Microsoft\NET Framework Setup\NDP\v4\Client`

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- **Is**

## REGDB\_KEYPATH\_DOTNET\_40\_FULL

REGDB\_KEYPATH\_DOTNET\_40\_FULL is a predefined constant whose value is the registry location (not including the root key) of the registry key for version 4.0 of the .NET Framework. It is defined as follows:

`Software\Microsoft\NET Framework Setup\NDP\v4\Full`

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- **Is**

## REGDB\_KEYPATH\_ISUNINSTINFO

ISUNINSTINFO is a predefined constant whose value is the registry location (not including the root key) of the InstallShield Uninstall Information key. It is defined as follows:

`Software\Microsoft\Windows\CurrentVersion\Uninstall\InstallShield Uninstall Information`

You cannot change the value of a predefined constant. You can use this constant to specify a key when calling a general registry-related function. This predefined constant is also supported when using the **Is** function.

### Used With

- [Is](#)

## REGDB\_KEYPATH\_RUN

REGDB\_KEYPATH\_RUN is a predefined constant whose value is the registry location (not including the root key) of the general application paths key, that is, `Software\Microsoft\Windows\CurrentVersion\Run\`. You can use this constant to specify a key when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_KEYPATH\_RUNONCE

REGDB\_KEYPATH\_RUNONCE is a predefined constant whose value is the registry location (not including the root key) of the general application paths key, that is, `Software\Microsoft\Windows\CurrentVersion\RunOnce\`. You can use this constant to specify a key when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_KEYPATH\_RUNONCEEX

REGDB\_KEYPATH\_RUNONCEEX is a predefined constant whose value is the registry location (not including the root key) of the general application paths key, that is, `Software\Microsoft\Windows\CurrentVersion\RunOnceEx\`. You can use this constant to specify a key when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_KEYPATH\_SHAREDDELLS

REGDB\_KEYPATH\_SHAREDDELLS is a predefined constant whose value is the registry location (not including the root key) of the general application paths key, that is, `Software\Microsoft\Windows\CurrentVersion\SharedDLLs\`. You can use this constant to specify a key when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_KEYPATH\_UNINSTALL

REGDB\_KEYPATH\_UNINSTALL is a predefined constant whose value is the registry location (not including the root key) of the general uninstallation key for applications, that is, `Software\Microsoft\Windows\CurrentVersion\Uninstall\`. You can use this constant to specify a key when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_KEYPATH\_WINCURRVER

REGDB\_KEYPATH\_WINCURRVER is a predefined constant whose value is the registry location (not including the root key) of the Windows current version key, that is, `Software\Microsoft\Windows\CurrentVersion\`. You can use this constant to specify a key when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_KEYPATH\_WINCURRVER\_AUTO

The value of this system variable is [REGDB\\_KEYPATH\\_WINCURRVER](#) on Windows 95, Windows 95, and Windows Me, and [REGDB\\_KEYPATH\\_WINNTCURRVER](#) on Windows NT, Windows 2000, and Windows XP and later.

## REGDB\_KEYPATH\_WINNTCURRVER

REGDB\_KEYPATH\_WINNTCURRVER is a predefined constant whose value is the registry location (not including the root key) of the Windows NT current version key, that is, Software\Microsoft\Windows NT\CurrentVersion\. You can use this constant to specify a key when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_KEYS

REGDB\_KEYS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBQueryKey](#)

## REGDB\_NAMES

REGDB\_NAMES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBQueryKey](#)

## REGDB\_NUMBER

REGDB\_NUMBER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBGetAppInfo](#)
- [RegDBGetKeyValueEx](#)
- [RegDBSetKeyValueEx](#)
- [RegDBSetAppInfo](#)

## REGDB\_STRING

REGDB\_STRING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBGetAppInfo](#)
- [RegDBGetKeyValueEx](#)
- [RegDBSetKeyValueEx](#)
- [RegDBSetAppInfo](#)

## REGDB\_STRING\_EXPAND

REGDB\_STRING\_EXPAND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBSetAppInfo](#)
- [RegDBGetKeyValueEx](#)
- [RegDBSetKeyValueEx](#)
- [RegDBGetAppInfo](#)

## REGDB\_STRING\_MULTI

REGDB\_STRING\_MULTI is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBGetAppInfo](#)
- [RegDBGetKeyValueEx](#)
- [RegDBSetKeyValueEx](#)
- [RegDBSetAppInfo](#)

## REGDB\_UNINSTALL\_COMMENTS

REGDB\_UNINSTALL\_COMMENTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_CONTACT

REGDB\_UNINSTALL\_CONTACT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_DISPLAYICON

REGDB\_UNINSTALL\_DISPLAYICON is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_DISPLAY\_VERSION

---

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_DISPLAY\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_HELPLINK

REGDB\_UNINSTALL\_HELPLINK is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_HELPTELEPHONE

REGDB\_UNINSTALL\_HELPTELEPHONE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_INSTALLDATE

REGDB\_UNINSTALL\_INSTALLDATE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_INSTALLLOC

---

**Project** • This information applies to InstallScript projects.

REGDB\_UNINSTALL\_INSTALLLOC is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)

- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_INSTALLSOURCE

REGDB\_UNINSTALL\_INSTALLSOURCE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_LANGUAGE

REGDB\_UNINSTALL\_LANGUAGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_LOGFILE

---

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_LOGFILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_MAINT\_OPTION

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_MAINT\_OPTION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_MAJOR\_VERSION

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_MAJOR\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_MAJOR\_VERSION\_OLD

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_MAJOR\_VERSION\_OLD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_MINOR\_VERSION

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_MINOR\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_MINOR\_VERSION\_OLD

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_MINOR\_VERSION\_OLD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_MODIFYPATH

REGDB\_UNINSTALL\_MODIFYPATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_NAME

REGDB\_UNINSTALL\_NAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_NOMODIFY

REGDB\_UNINSTALL\_NOMODIFY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_NOREMOVE

REGDB\_UNINSTALL\_NOREMOVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_NOREPAIR

REGDB\_UNINSTALL\_NOREPAIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_PRODUCTGUID

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_PRODUCTGUID is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_PRODUCTID

REGDB\_UNINSTALL\_PRODUCTID is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_PUBLISHER

REGDB\_UNINSTALL\_PUBLISHER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

# REGDB\_UNINSTALL\_README

REGDB\_UNINSTALL\_README is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [RegDBDeleteItem](#)

- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_REGCOMPANY

REGDB\_UNINSTALL\_REGCOMPANY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_REGOWNER

REGDB\_UNINSTALL\_REGOWNER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_STRING

---

**Project** • This information applies to InstallScript projects.

REGDB\_UNINSTALL\_STRING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_SYSTEMCOMPONENT

REGDB\_UNINSTALL\_SYSTEMCOMPONENT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_URLINFOABOUT

REGDB\_UNINSTALL\_URLINFOABOUT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_URLUPDATEINFO

REGDB\_UNINSTALL\_URLUPDATEINFO is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)
- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_UNINSTALL\_VERSION

**Project** ▪ This information applies to InstallScript projects.

REGDB\_UNINSTALL\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBDeleteItem](#)

- [RegDBGetItem](#)
- [RegDBSetItem](#)

## REGDB\_VALUENAME\_APPPATH

REGDB\_VALUENAME\_APPPATH is a predefined constant whose value is the path value name under the application path key, that is, *Path*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_APPPATHDEFAULT

REGDB\_VALUENAME\_APPPATHDEFAULT is a predefined constant whose value is the default value name under the application path key, that is, a null string (""). You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_INSTALL

REGDB\_VALUENAME\_INSTALL is a predefined constant whose value is *Install*. You can use this constant to specify a value when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_INSTALLSUCCESS

REGDB\_VALUENAME\_INSTALLSUCCESS is a predefined constant whose value is *InstallSuccess*. You can use this constant to specify a value when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_SP

REGDB\_VALUENAME\_INSTALL is a predefined constant whose value is *SP*. You can use this constant to specify a value when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_COMMENTS

REGDB\_VALUENAME\_UNINSTALL\_COMMENTS is a predefined constant whose value is the comments value name under the application uninstallation key—that is, *Comments*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_CONTACT

REGDB\_VALUENAME\_UNINSTALL\_CONTACT is a predefined constant whose value is the contact value name under the application uninstallation key—that is, *Contact*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_DISPLAYICON

REGDB\_VALUENAME\_UNINSTALL\_DISPLAYICON is a predefined constant whose value is the display icon value name under the application uninstallation key—that is, *DisplayIcon*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_DISPLAYNAME

REGDB\_VALUENAME\_UNINSTALL\_DISPLAYNAME is a predefined constant whose value is the display name value name under the application uninstallation key—that is, *DisplayName*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_DISPLAYVERSION

REGDB\_VALUENAME\_UNINSTALL\_DISPLAYVERSION is a predefined constant whose value is the display version value name under the application uninstallation key—that is, *DisplayVersion*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_HELPLINK

REGDB\_VALUENAME\_UNINSTALL\_HELPLINK is a predefined constant whose value is the help link value name under the application uninstallation key—that is, *HelpLink*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_HELPTELEPHONE

REGDB\_VALUENAME\_UNINSTALL\_HELPTELEPHONE is a predefined constant whose value is the help telephone value name under the application uninstallation key—that is, *HelpTelephone*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_INSTALLDATE

REGDB\_VALUENAME\_UNINSTALL\_INSTALLDATE is a predefined constant whose value is the installation date value name under the application uninstallation key—that is, *InstallDate*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_INSTALLLOCATION

REGDB\_VALUENAME\_UNINSTALL\_INSTALLLOCATION is a predefined constant whose value is the installation location value name under the application uninstallation key—that is, *InstallLocation*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_INSTALLSOURCE

REGDB\_VALUENAME\_UNINSTALL\_INSTALLSOURCE is a predefined constant whose value is the installation source value name under the application uninstallation key—that is, *InstallSource*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_LANGUAGE

REGDB\_VALUENAME\_UNINSTALL\_LANGUAGE is a predefined constant whose value is the language value name under the application uninstallation key—that is, *Language*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_LOGFILE

REGDB\_VALUENAME\_UNINSTALL\_LOGFILE is a predefined constant whose value is the log file value name under the application uninstallation key—that is, *LogFile*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_LOGMODE

REGDB\_VALUENAME\_UNINSTALL\_LOGMODE is a predefined constant whose value is the log mode value name under the application uninstallation key—that is, *LogMode*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_MAJORVERSION

REGDB\_VALUENAME\_UNINSTALL\_MAJORVERSION is a predefined constant whose value is the major version value name under the application uninstallation key—that is, *VersionMajor*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_MAJORVERSION\_OLD

REGDB\_VALUENAME\_UNINSTALL\_MAJORVERSION\_OLD is a predefined constant whose value is the major version value name under the application uninstallation key—that is, *MajorVersion*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_MINORVERSION

REGDB\_VALUENAME\_UNINSTALL\_MINORVERSION is a predefined constant whose value is the minor version value name under the application uninstallation key—that is, *VersionMinor*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_MINORVERSION\_OLD

REGDB\_VALUENAME\_UNINSTALL\_MINORVERSION\_OLD is a predefined constant whose value is the minor version value name under the application uninstallation key—that is, *MinorVersion*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_MODIFYPATH

REGDB\_VALUENAME\_UNINSTALL\_MODIFYPATH is a predefined constant whose value is the modify path value name under the application uninstallation key—that is, *ModifyPath*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_NOMODIFY

REGDB\_VALUENAME\_UNINSTALL\_NOMODIFY is a predefined constant whose value is the no modify value name under the application uninstallation key—that is, *NoModify*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_NOREMOVE

REGDB\_VALUENAME\_UNINSTALL\_NOREMOVE is a predefined constant whose value is the no remove value name under the application uninstallation key—that is, *NoRemove*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_NOREPAIR

REGDB\_VALUENAME\_UNINSTALL\_NOREPAIR is a predefined constant whose value is the no repair value name under the application uninstallation key—that is, *NoRepair*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_PRODUCTGUID

REGDB\_VALUENAME\_UNINSTALL\_PRODUCTGUID is a predefined constant whose value is the product GUID value name under the application uninstallation key—that is, *ProductGuid*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_PRODUCTID

REGDB\_VALUENAME\_UNINSTALL\_PRODUCTID is a predefined constant whose value is the product ID value name under the application uninstallation key—that is, *ProductId*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_PUBLISHER

REGDB\_VALUENAME\_UNINSTALL\_PUBLISHER is a predefined constant whose value is the publisher value name under the application uninstallation key—that is, *Publisher*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_README

REGDB\_VALUENAME\_UNINSTALL\_README is a predefined constant whose value is the readme value name under the application uninstallation key—that is, *Readme*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_REGCOMPANY

REGDB\_VALUENAME\_UNINSTALL\_REGCOMPANY is a predefined constant whose value is the reg company value name under the application uninstallation key—that is, *RegCompany*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_REGOWNER

REGDB\_VALUENAME\_UNINSTALL\_REGOWNER is a predefined constant whose value is the reg owner value name under the application uninstallation key—that is, *RegOwner*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_SYSTEMCOMPONENT

REGDB\_VALUENAME\_UNINSTALL\_SYSTEMCOMPONENT is a predefined constant whose value is the system component value name under the application uninstallation key—that is, *SystemComponent*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_UNINSTALLSTRING

REGDB\_VALUENAME\_UNINSTALL\_UNINSTALLSTRING is a predefined constant whose value is the uninstallation string value name under the application uninstallation key—that is, *UninstallString*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_URLINFOABOUT

REGDB\_VALUENAME\_UNINSTALL\_URLINFOABOUT is a predefined constant whose value is the URL info about value name under the application uninstallation key—that is, *URLInfoAbout*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_URLUPDATEINFO

REGDB\_VALUENAME\_UNINSTALL\_URLUPDATEINFO is a predefined constant whose value is the URL date info value name under the application uninstallation key—that is, *URLDateInfo*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALL\_VERSION

REGDB\_VALUENAME\_UNINSTALL\_VERSION is a predefined constant whose value is the application version value name under the application uninstallation key—that is, *Version*. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_UNINSTALLKEY

REGDB\_VALUENAME\_UNINSTALLKEY is a predefined constant whose value is defined as UninstallKey. You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_WINCURRVER\_REGORGANIZATION

REGDB\_VALUENAME\_WINCURRVER\_REGORGANIZATION is a predefined constant whose value is the registered organization value name under the Windows (on Windows 95, Windows 95, and Windows Me) or Windows NT (on Windows 95, Windows 95, and Windows Me) current version key, that is, "RegisteredOrganization". You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_VALUENAME\_WINCURRVER\_REGOWNER

REGDB\_VALUENAME\_WINCURRVER\_REGOWNER is a predefined constant whose value is the registered owner value name under the Windows (on Windows 95, Windows 95, and Windows Me) or Windows NT (on Windows 95, Windows 95, and Windows Me) current version key, that is, "RegisteredOwner". You can use this constant to specify a value name when calling a general registry-related function. You cannot change the value of a predefined constant.

## REGDB\_WINCURRVER\_REGORGANIZATION

REGDB\_WINCURRVER\_REGORGANIZATION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBGetItem](#)

## REGDB\_WINCURRVER\_REGOWNER

REGDB\_WINCURRVER\_REGOWNER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegDBGetItem](#)

## REGFONT\_OPTION\_DEFAULT

REGFONT\_OPTION\_DEFAULT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegisterFontResource](#)

## REGFONT\_OPTION\_DONTBROADCASTFONTCHANGEMSG

REGFONT\_OPTION\_DONTBROADCASTFONTCHANGEMSG is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegisterFontResource](#)

## REGFONT\_OPTION\_DONTUPDATEREGISTRY

REGFONT\_OPTION\_DONTUPDATEREGISTRY is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [RegisterFontResource](#)

## REGISTRYFUNCTIONS\_USETEXTSUBS

REGISTRYFUNCTIONS\_USETEXTSUBS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Disable](#)
- [Enable](#)

## REMOTE\_DRIVE

REMOTE\_DRIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetValidDrivesList](#)

## REMOVE

REMOVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceBitmap](#)

## REMOVEABLE\_DRIVE

REMOVEABLE\_DRIVE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetValidDrivesList](#)

## REMOVEALL

---

**Project** • This information applies to InstallScript projects.

REMOVEALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SdWelcomeMaint](#)

## REPAIR

---

**Project** • This information applies to InstallScript projects.

REPAIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SdWelcomeMaint](#)

## REPLACE

REPLACE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ConfigAdd](#)
- [AddFolderIcon](#)
- [FileInsertLine](#)
- [BatchAdd](#)
- [ReplaceFolderIcon](#)

## RESET

RESET is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FindFile](#)

## RESTART

RESTART is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [FileGrep](#)
- [PathFind](#)
- [ConfigFind](#)
- [BatchFind](#)

## ROOT

ROOT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [DeleteDir](#)

## RUN\_MAXIMIZED

RUN\_MAXIMIZED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [AddFolderIcon](#)
- [ReplaceFolderIcon](#)

## RUN\_MINIMIZED

RUN\_MINIMIZED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [QueryProgItem](#)
- [AddFolderIcon](#)
- [ReplaceFolderIcon](#)

## SELECTFOLDER

SELECTFOLDER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SelectFolder](#)

## SELFREGISTER

SELFREGISTER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [VerUpdateFile](#)
- [XCopyFile](#)

## SELFREGISTERBATCH

SELFREGISTERBATCH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Enable`
- `Disable`

## SELFREGISTRATIONPROCESS

SELFREGISTRATIONPROCESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Do`

## SERIAL

SERIAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `GetSystemInfo`

## SERVICE\_ADAPTER

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_ADAPTER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- `SERVICE_IS_PARAMS`

## SERVICE\_ALL\_ACCESS

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_ALL\_ACCESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_AUTO\_START

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_AUTO\_START is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_BOOT\_START

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_BOOT\_START is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_CHANGE\_CONFIG

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_CHANGE\_CONFIG is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_CONTINUE\_PENDING

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_CONTINUE\_PENDING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_STATUS

## SERVICE\_DEMAND\_START

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_DEMAND\_START is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_DISABLED

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_DISABLED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_ENUMERATE\_DEPENDENTS

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_ENUMERATE\_DEPENDENTS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_PARAMS](#)

## SERVICE\_ERROR\_CRITICAL

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_ERROR\_CRITICAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_PARAMS](#)

## SERVICE\_ERROR\_IGNORE

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_ERROR\_IGNORE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_PARAMS](#)

## SERVICE\_ERROR\_NORMAL

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_ERROR\_NORMAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_PARAMS](#)

## SERVICE\_ERROR\_SEVERE

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_ERROR\_SEVERE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_FILE\_SYSTEM\_DRIVER

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_FILE\_SYSTEM\_DRIVER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_FLAG\_DIFX\_32

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript Object

SERVICE\_FLAG\_DIFX\_32 is a predefined constant that is used to represent a value that can be set as a bit flag in the system variable ENABLED\_ISERVICES. You cannot change the value of a predefined constant.

## SERVICE\_FLAG\_DIFX\_AMD64

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript Object

SERVICE\_FLAG\_DIFX\_AMD64 is a predefined constant that is used to represent a value that can be set as a bit flag in the system variable ENABLED\_ISERVICES. You cannot change the value of a predefined constant.

## SERVICE\_FLAG\_DIFX\_IA64

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript Object*

SERVICE\_FLAG\_DIFX\_IA64 is a predefined constant that is used to represent a value that can be set as a bit flag in the system variable [ENABLED\\_ISERVICES](#). You cannot change the value of a predefined constant.

## SERVICE\_FLAG\_ISFONTREG

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript Object*

SERVICE\_FLAG\_ISFONTREG is a predefined constant that is used to represent a value that can be set as a bit flag in the system variable [ENABLED\\_ISERVICES](#). If the expression `ENABLED_ISERVICES & SERVICE_FLAG_ISFONTREG` is equal to a non-zero value, global font registration is currently enabled. You cannot change the value of a predefined constant.

## SERVICE\_INTERACTIVE\_PROCESS

**Project** ▪ This information applies to *InstallScript* projects.

SERVICE\_INTERACTIVE\_PROCESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_PARAMS](#)

## SERVICE\_INTERROGATE

**Project** ▪ This information applies to *InstallScript* projects.

SERVICE\_INTERROGATE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_PARAMS](#)

## SERVICE\_ISFONTREG

SERVICE\_ISFONTREG is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Disable](#)

## SERVICE\_ISUPDATE

---

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## SERVICE\_KERNEL\_DRIVER

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_KERNEL\_DRIVER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_PARAMS](#)

## SERVICE\_PAUSED

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_PAUSED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- [SERVICE\\_IS\\_STATUS](#)

# SERVICE\_PAUSE\_CONTINUE

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_PAUSE\_CONTINUE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- SERVICE\_IS\_PARAMS

# SERVICE\_PAUSE\_PENDING

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_PAUSE\_PENDING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- SERVICE\_IS\_STATUS

# SERVICE\_QUERY\_CONFIG

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_QUERY\_CONFIG is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- SERVICE\_IS\_PARAMS

# SERVICE\_QUERY\_STATUS

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_QUERY\_STATUS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_RECOGNIZER\_DRIVER

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_RECOGNIZER\_DRIVER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_RUNNING

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_RUNNING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_STATUS

## SERVICE\_START

---

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_START is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_START\_PENDING

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_START\_PENDING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_STATUS

## SERVICE\_STOP

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_STOP is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_STOPPED

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_STOPPED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_STATUS

## SERVICE\_STOP\_PENDING

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_STOP\_PENDING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_STATUS

## SERVICE\_SYSTEM\_START

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_SYSTEM\_START is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_USER\_DEFINED\_CONTROL

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_USER\_DEFINED\_CONTROL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

## SERVICE\_WIN32\_OWN\_PROCESS

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_WIN32\_OWN\_PROCESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- SERVICE\_IS\_PARAMS

# SERVICE\_WIN32\_SHARE\_PROCESS

**Project** ▪ This information applies to InstallScript projects.

SERVICE\_WIN32\_SHARE\_PROCESS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

## Used With

- `SERVICE_IS_PARAMS`

# SETUPTYPE

SETUPTYPE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- `SetupType`

# SETUPTYPE\_INFO\_DESCRIPTION

SETUPTYPE\_INFO\_DESCRIPTION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- `FeatureSetupTypeGetData`

# SETUPTYPE\_INFO\_DISPLAYNAME

SETUPTYPE\_INFO\_DISPLAYNAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- `FeatureSetupTypeGetData`

# SETUPTYPE\_STR\_COMPACT

SETUPTYPE\_STR\_COMPACT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `FeatureStandardSetupTypeSet`

## SETUPTYPE\_STR\_COMPLETE

SETUPTYPE\_STR\_COMPLETE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `FeatureStandardSetupTypeSet`

## SETUPTYPE\_STR\_CUSTOM

SETUPTYPE\_STR\_CUSTOM is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `FeatureStandardSetupTypeSet`

## SETUPTYPE\_STR\_TYPICAL

SETUPTYPE\_STR\_TYPICAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `FeatureStandardSetupTypeSet`

## SETUP\_PACKAGE

---

**Project** • This information applies to InstallScript projects.

SETUP\_PACKAGE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- `Is`

## SEVERE

SEVERE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MessageBox](#)
- [SprintfBox](#)

## SHAREDFILE

SHAREDFILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [XCopyFile](#)
- [VerUpdateFile](#)
- [DeinstallStart](#)
- [InstallationInfo](#)
- [System](#)

## SILENTMODE

SILENTMODE is a predefined constant that can be used to test whether or not a setup is running in silent mode. For more information, refer to the InstallShield system variable [MODE](#).

## SKIN\_LOADED

---

**Project** ▪ This information applies to InstallScript projects.

SKIN\_LOADED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Is](#)

## SQL\_BATCH\_INSTALL

SQL\_BATCH\_INSTALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SQLRTGetBatchList](#)

## SQL\_BATCH\_UNINSTALL

SQL\_BATCH\_UNINSTALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SQLRTGetBatchList](#)

## SQL\_BROWSE\_ALIAS

SQL\_BROWSE\_ALIAS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SQLRTGetBrowseOption](#)
- [SQLRTSetBrowseOption](#)

## SQL\_BROWSE\_ALL

SQL\_BROWSE\_ALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SQLRTGetBrowseOption](#)
- [SQLRTSetBrowseOption](#)

## SQL\_BROWSE\_LOCAL

SQL\_BROWSE\_LOCAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SQLRTGetBrowseOption](#)
- [SQLRTSetBrowseOption](#)

## SQL\_BROWSE\_REMOTE

SQL\_BROWSE\_REMOTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SQLRTGetBrowseOption](#)
- [SQLRTSetBrowseOption](#)

## SQL\_ERROR\_GET\_SCHEMA\_VERSION

SQL\_ERROR\_GET\_SCHEMA\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SQLRTGetComponentScriptError](#)
- [SQLRTGetComponentScriptError2](#)

## SQL\_ERROR\_SCRIPT\_COMMAND\_ERROR

SQL\_ERROR\_SCRIPT\_COMMAND\_ERROR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SQLRTGetComponentScriptError](#)
- [SQLRTGetComponentScriptError2](#)

## SQL\_ERROR\_SCRIPT\_CONNECTION\_NOT\_OPEN

SQL\_ERROR\_SCRIPT\_CONNECTION\_NOT\_OPEN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SQLRTGetComponentScriptError](#)
- [SQLRTGetComponentScriptError2](#)

## SQL\_ERROR\_SCRIPT\_UNABLE\_OPEN\_FILE

SQL\_ERROR\_SCRIPT\_UNABLE\_OPEN\_FILE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SQLRTGetComponentScriptError](#)
- [SQLRTGetComponentScriptError2](#)

## SQL\_ERROR\_SET\_SCHEMA\_VERSION

SQL\_ERROR\_SET\_SCHEMA\_VERSION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SQLRTGetComponentScriptError](#)
- [SQLRTGetComponentScriptError2](#)

## SRCINSTALLDIR

**Note** • *SRCTARGETDIR* replaces *SRCINSTALLDIR*.

SRCINSTALLDIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [VarRestore](#)
- [VarSave](#)

## SRCTARGETDIR

**Note** • *SRCTARGETDIR* replaces *SRCINSTALLDIR*.

SRCTARGETDIR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [VarRestore](#)
- [VarSave](#)

## SSP\_PROPERTY\_NO\_NEW\_INSTALL\_HIGHLIGHT

SSP\_PROPERTY\_NO\_NEW\_INSTALL\_HIGHLIGHT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetShortcutProperty](#)

## SSP\_PROPERTY\_NO\_STARTSCREEN\_PIN

SSP\_PROPERTY\_NO\_STARTSCREEN\_PIN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetShortcutProperty](#)

## SSP\_PROPERTY\_PREVENT\_PINNING

SSP\_PROPERTY\_PREVENT\_PINNING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetShortcutProperty](#)

## STANDARD\_RIGHTS\_ALL

STANDARD\_RIGHTS\_ALL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## STANDARD\_RIGHTS\_EXECUTE

STANDARD\_RIGHTS\_EXECUTE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## STANDARD\_RIGHTS\_READ

STANDARD\_RIGHTS\_READ is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## STANDARD\_RIGHTS\_REQUIRED

STANDARD\_RIGHTS\_REQUIRED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

**Used With**

- [SERVICE\\_IS\\_PARAMS](#)
- [SetObjectPermissions](#)

## STANDARD\_RIGHTS\_WRITE

STANDARD\_RIGHTS\_WRITE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

**Used With**

- [SetObjectPermissions](#)

## STATUS

STATUS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [PlaceWindow](#)
- [Enable](#)
- [Disable](#)

## STATUSBAR

STATUSBAR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetColor](#)

## STATUSBBRD

STATUSBBRD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Enable](#)
- [Disable](#)

## STATUSDLG

STATUSDLG is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceWindow](#)
- [Enable](#)
- [Disable](#)

## STATUSEX

STATUSEX is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceWindow](#)
- [Enable](#)
- [Disable](#)

## STATUSOLD

STATUSOLD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceWindow](#)
- [Enable](#)
- [Disable](#)

## STRINGLIST

STRINGLIST is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [ListCreate](#)

## STYLE\_BOLD

STYLE\_BOLD is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetFont](#)
- [SetFont](#)

## STYLE\_ITALIC

STYLE\_ITALIC is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetFont](#)
- [SetFont](#)

## STYLE\_NORMAL

STYLE\_NORMAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetFont](#)
- [SetFont](#)

## STYLE\_SHADOW

STYLE\_SHADOW is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [SetFont](#)

## STYLE\_UNDERLINE

STYLE\_UNDERLINE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetFont](#)
- [SetFont](#)

## SW\_MAXIMIZE

SW\_MAXIMIZE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ShowProgramFolder](#)

## SW\_MINIMIZE

SW\_MINIMIZE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ShowProgramFolder](#)

## SW\_RESTORE

SW\_RESTORE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ShowProgramFolder](#)

## SW\_SHOW

SW\_SHOW is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [ShowProgramFolder](#)

## SYNCHRONIZE

SYNCHRONIZE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

**Used With**

- [SERVICE\\_IS\\_PARAMS](#)
- [SetObjectPermissions](#)

## SYS\_BOOTMACHINE

SYS\_BOOTMACHINE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [System](#)
- [RebootDialog](#)
- [SdFinishReboot](#)

## SYSTEM\_DPI

SYSTEM\_DPI is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetSystemInfo](#)

## SYSTEM\_DPI\_SCALING

SYSTEM\_DPI\_SCALING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetSystemInfo](#)

# TBYTES

TBYTES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [ConvertSizeToUnits](#)
- [StrConvertSizeUnit](#)

# TILED

TILED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [PlaceBitmap](#)

# TIME

TIME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [GetSystemInfo](#)

# TRUE

TRUE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

## Used With

- [AskOptions](#)
- [CtrlSetMultCurSel](#)
- [DialogSetInfo](#)
- [FeatureAddItem](#)
- [FeatureGetData](#)
- [FeatureIsItemSelected](#)
- [FeatureSelectItem](#)
- [FeatureTotalSize](#)

- [LongPathToQuote](#)
- [SdDiskSpace2](#)
- [SelectDir](#)
- [SdShowMsg](#)
- [SQLDatabaseBrowse](#)
- [SQLRTConnect](#)
- [SQLRTConnect2](#)
- [SQLRTConnectDB](#)
- [SQLRTGetDatabases](#)
- [SQLRTGetServers](#)
- [SQLRTGetServers2](#)
- [SQLRTPutConnectionAuthentication](#)
- [SQLRTTestConnection](#)
- [SQLRTTestConnection2](#)
- [SQLServerSelectLogin](#)
- [SQLServerSelectLogin2](#)

## TTFONTFILEINFO\_FONTTITLE

TTFONTFILEINFO\_FONTTITLE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetTrueTypeFontFileInfo](#)

## TYPICAL

TYPICAL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SdSetupType](#)
- [SetupType](#)

## UPDATE\_SERVICE\_INSTALL

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## UPDATESERVICECOMPONENT

**Project** ▪ This information applies to InstallScript projects.

This constant is obsolete. For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## UPPER\_LEFT

UPPER\_LEFT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceBitmap](#)
- [PlaceWindow](#)

## UPPER\_RIGHT

UPPER\_RIGHT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [PlaceBitmap](#)
- [PlaceWindow](#)

## URL

**Project** ▪ This information applies to InstallScript projects.

URL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Is`

## USER\_ADMINISTRATOR

USER\_ADMINISTRATOR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Is`

## USER\_INADMINGROUP

USER\_INADMINGROUP is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Is`

## USER\_POWERUSER

---

**Project** ▪ This information applies to InstallScript projects.

USER\_POWERUSER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Is`

## USE\_LOADED\_SKIN

---

**Project** ▪ This information applies to InstallScript projects.

USE\_LOADED\_SKIN is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `Disable`
- `Enable`

## VALID\_PATH

VALID\_PATH is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Is](#)

## VERSION\_COMPARE\_RESULT\_NEWER

---

**Project** ▪ This information applies to InstallScript projects.

VERSION\_COMPARE\_RESULT\_NEWER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerProductCompareVersions](#)

## VERSION\_COMPARE\_RESULT\_NEWER\_NOT\_SUPPORTED

---

**Project** ▪ This information applies to InstallScript projects.

VERSION\_COMPARE\_RESULT\_NEWER\_NOT\_SUPPORTED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerProductCompareVersions](#)

## VERSION\_COMPARE\_RESULT\_NOT\_INSTALLED

---

**Project** ▪ This information applies to InstallScript projects.

VERSION\_COMPARE\_RESULT\_NOT\_INSTALLED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerProductCompareVersions](#)

## VERSION\_COMPARE\_RESULT\_OLDER

**Project** ▪ This information applies to InstallScript projects.

VERSION\_COMPARE\_RESULT\_OLDER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerProductCompareVersions](#)

## VERSION\_COMPARE\_RESULT\_SAME

**Project** ▪ This information applies to InstallScript projects.

VERSION\_COMPARE\_RESULT\_SAME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerProductCompareVersions](#)

## VERSION\_PREVIOUS\_VERSION\_DELIMITER

**Project** ▪ This information applies to InstallScript projects.

VERSION\_PREVIOUS\_VERSION\_DELIMITER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerProductCompareVersions](#)

## VER\_DLL\_NOT\_FOUND

VER\_DLL\_NOT\_FOUND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerSearchAndUpdateFile](#)

## VER\_UPDATE\_ALWAYS

VER\_UPDATE\_ALWAYS is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerUpdateFile](#)
- [VerSearchAndUpdateFile](#)

## VER\_UPDATE\_COND

VER\_UPDATE\_COND is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [VerSearchAndUpdateFile](#)

## VIDEO

VIDEO is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## VIRTUAL\_MACHINE\_TYPE

VIRTUAL\_MACHINE\_TYPE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## VOLUMELABEL

VOLUMELABEL is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [GetSystemInfo](#)

## WARNING

WARNING is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [MessageBox](#)
- [SprintfBox](#)

## WEB\_BASED\_SETUP

**Project** ▪ This information applies to InstallScript projects.

WEB\_BASED\_SETUP is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Is](#)

## WELCOME

WELCOME is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [Welcome](#)

## WHITE

WHITE is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- [SetTitle](#)

## WILL\_REBOOT

WILL\_REBOOT is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or event handlers. You cannot change the value of a predefined constant.

**Used With**

- [RebootDialog](#)
- [SdFinishReboot](#)

## WINDOWS\_SHARED

WINDOWS\_SHARED is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Is](#)

## WINMAJOR

WINMAJOR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetSystemInfo](#)

## WINMINOR

WINMINOR is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [GetSystemInfo](#)

## WOW64FSREDIRECTION

---

**Project** ▪ *This information applies to InstallScript projects.*

WOW64FSREDIRECTION is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

**Used With**

- [Disable](#)
- [Enable](#)

## WRITE\_DAC

WRITE\_DAC is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- `SERVICE_IS_PARAMS`
- `SetObjectPermissions`

## WRITE\_OWNER

WRITE\_OWNER is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions or assigned to one or more system variables. You cannot change the value of a predefined constant.

### Used With

- `SERVICE_IS_PARAMS`
- `SetObjectPermissions`

## YELLOW

YELLOW is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `SetColor`
- `SetTitle`

## YES

YES is a predefined constant that is used to represent a value that is passed to or returned by one or more built-in functions. You cannot change the value of a predefined constant.

### Used With

- `AskYesNo`
- `SdLicense`
- `SdConfirmNewDir`
- `SdConfirmRegistration`

# \_MAX\_PATH

**Project** ▪ *This information applies to InstallScript projects.*

MAX\_PATH is a predefined constant that is used to represent the maximum length of a path variable that is passed to a Windows API function. The following sample code lines illustrate possible uses of \_MAX\_PATH:

```
string szPath[_MAX_PATH]; /* variable declaration */  
...  
Kernel32.GetTempPathA( _MAX_PATH, szPath ); /* Windows API function call */
```

# Predefined Script Variables

This section includes a list of predefined script variables that are reserved during script compilation.

- `__FILE__`
- `__LINE__`
- `BASICMSI`
- `INSTALLSCRIPTMSI`
- `INSTALLSCRIPTMSIEUI`
- `ISUS_PRODUCT_CODE`
- `SERVICE_IS_PARAMS`
- `SERVICE_IS_STATUS`
- `SUITE_HOSTED`

## `__FILE__`

During script compilation this reserved identifier is replaced by a string that contains the fully qualified name of the source file in which `__FILE__` resides. `__FILE__` can be specified anywhere in a script where a string constant is allowed, but it is most useful when used with `__LINE__` for simple debugging. For example, by constructing a statement like the one below and copying it to strategic locations in your source files during testing, you can easily associate specific parts of your setup with specific sections of your script as you observe your setup run.

```

    sprintfBox (INFORMATION, "", "File: %s\nLine:%ld",
               __FILE__, __LINE__);

```

Note that the path will be the location from which the file was compiled, not the location from which the setup is being run. If necessary, the `ParsePath` function can be called with `__FILE__` in the second parameter to extract parts of the fully qualified file name. The code fragment below extracts the file name and displays it.

```

    ParsePath (svReturnString, __FILE__, FILENAME);
    MessageBox (svReturnString, INFORMATION);

```

For more complete and powerful debugging, use the InstallScript Debugger by clicking Debug on the Build menu in InstallShield. For more information, see the InstallScript Debugger Help.

## `__LINE__`

During setup compilation, this reserved identifier is replaced by the number of the source file line in which `__LINE__` resides. Note that `__LINE__` can be specified anywhere in a script where a number constant is allowed, but it is most useful when used with `__FILE__` for simple debugging. For example, by constructing a statement like the one below and copying it to strategic locations in your source files during testing, you can easily associate specific parts of your setup with specific sections of your script as you observe your setup run.

```

    sprintfBox (INFORMATION, "", "File: %s\nLine:%ld", __FILE__, __LINE__);

```

For more complete and powerful debugging, use the InstallScript Debugger by clicking Debug on the Build menu in InstallShield. For more information, see the InstallScript Debugger Help.

## BASICMSI

The BASICMSI script variable is defined for Basic MSI projects, but it is undefined and evaluates as zero in InstallScript MSI projects and in InstallScript projects.

**Note** ▪ BASICMSI is not a preprocessor switch; therefore, you can use this script variable to create script code that will work differently in different project types without being recompiled.

You can use BASICMSI to write a single script that produces different behavior in the different project types by including code such as the following in your script:

```
if( BASICMSI ) then
    //Code for Basic MSI projects
else
    //Code for InstallScript MSI or InstallScript projects
endif;
```

## INSTALLSCRIPTMSI

INSTALLSCRIPTMSI is defined in InstallScript MSI and Basic MSI projects, but it is undefined and evaluates as zero in InstallScript projects.

**Note** ▪ INSTALLSCRIPTMSI is not a preprocessor switch; therefore, you can use this script variable to create script code that will work differently in the two project types without being recompiled.

You can use INSTALLSCRIPTMSI to write a single script that produces different behavior in the different project types by including code such as the following in your script:

```
if( INSTALLSCRIPTMSI ) then
    //Code for InstallScript MSI and Basic MSI projects...
else
    //Code for InstallScript projects...
endif;
```

## INSTALLSCRIPTMSIEEUI

The INSTALLSCRIPTMSIEEUI variable is set to enable an installation to determine at run time whether the InstallScript engine is used as the embedded user interface (UI) handler for an InstallScript MSI installation. This implementation is also known as the new style of InstallScript UI.

If the InstallScript engine is used as the embedded user interface handler for an InstallScript MSI installation, INSTALLSCRIPTMSIEEUI is set to TRUE. If it is not an embedded user interface handler, this variable is set to FALSE.

**Tip** ▪ For information on using the InstallScript engine as an embedded user interface handler for an InstallScript MSI installation, see *Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations*.

You can use `INSTALLSCRIPTMSIEUI` to write a single script that produces different behavior for the different user interface styles by including code such as the following in your script:

```
if( INSTALLSCRIPTMSIEUI ) then
    //Code for new-style InstallScript MSI installations
    //(InstallScript engine as an embedded UI handler)...
else
    //Code for traditional-style InstallScript MSI installations
    (InstallScript engine as an external UI handler)...
endif;
```

## ISUS\_PRODUCT\_CODE

The `ISUS_PRODUCT_CODE` variable is a read-write script variable which is set to `PRODUCT_GUID` during initialization. Like `PRODUCT_GUID`, this variable is not linked to a text-sub. Therefore, if customized, this script variable must be customized each time the setup is run, even during maintenance mode.

## SERVICE\_IS\_PARAMS

**Project** ▪ This information applies to InstallScript projects.

The `SERVICE_IS_PARAMS` variable is initialized automatically during installation initialization by a call to [ServiceInitParams](#).

**Note** ▪ Certain InstallScript service functions internally call the Windows API functions `OpenSCManager`, `CreateService`, or `ChangeServiceConfig`. The following members of the structured variable `SERVICE_IS_PARAMS` specify the corresponding arguments for these Windows API functions:

- `SERVICE_IS_PARAMS.lpMachineName`
- `SERVICE_IS_PARAMS.lpDatabaseName`
- `SERVICE_IS_PARAMS.dwDesiredAccess`
- `SERVICE_IS_PARAMS.dwServiceType`
- `SERVICE_IS_PARAMS.dwStartType`
- `SERVICE_IS_PARAMS.dwErrorControl`
- `SERVICE_IS_PARAMS.lpLoadOrderGroup`
- `SERVICE_IS_PARAMS.lpdwTagId`
- `SERVICE_IS_PARAMS.lpDependencies`
- `SERVICE_IS_PARAMS.lpServiceStartName`
- `SERVICE_IS_PARAMS.lpPassword`

The following members of `SERVICE_IS_PARAMS` control how the installation behaves when waiting for a service to reach a desired state. See the descriptions for each member for additional information.

- `SERVICE_IS_PARAMS.nWaitHintMin`
- `SERVICE_IS_PARAMS.nWaitHintMax`
- `SERVICE_IS_PARAMS.nStartServiceWaitCount`

- *SERVICE\_IS\_PARAMS.nStopServiceWaitCount*

The SERVICE\_IS\_PARAMS script variable has the following members:

**Table 1 • SERVICE\_IS\_PARAMS Parameters**

| Member                | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dwServiceType</b>  | <p>This member can be set to these predefined constants:</p> <ul style="list-style-type: none"> <li>● SERVICE_WIN32_OWN_PROCESS</li> <li>● SERVICE_WIN32_SHARE_PROCESS</li> <li>● SERVICE_KERNEL_DRIVER</li> <li>● SERVICE_FILE_SYSTEM_DRIVER</li> <li>● SERVICE_ADAPTER</li> <li>● SERVICE_RECOGNIZER_DRIVER</li> <li>● SERVICE_INTERACTIVE_PROCESS</li> </ul>                                                                         |
| <b>dwStartType</b>    | <p>This member can be set to these predefined constants:</p> <ul style="list-style-type: none"> <li>● SERVICE_BOOT_START</li> <li>● SERVICE_SYSTEM_START</li> <li>● SERVICE_AUTO_START</li> <li>● SERVICE_DEMAND_START</li> <li>● SERVICE_DISABLED</li> </ul>                                                                                                                                                                           |
| <b>dwErrorControl</b> | <p>This member can be set to these predefined constants:</p> <ul style="list-style-type: none"> <li>● SERVICE_ERROR_IGNORE</li> <li>● SERVICE_ERROR_NORMAL</li> <li>● SERVICE_ERROR_SEVERE</li> <li>● SERVICE_ERROR_CRITICAL</li> </ul>                                                                                                                                                                                                 |
| <b>nWaitHintMin</b>   | <p>Specifies the minimum dwWaitHint wait time (in milliseconds). If a service specifies a dwWaitHint smaller than nWaitHintMin, nWaitHintMin is used instead as the wait time. This applies to both starting and stopping services.</p> <p>The default value of this member variable is 1000 (1 second), and is set by calling ServiceInitParams. See the MSDN documentation for more information on how a service sets dwWaitHint.</p> |

**Table 1** ■ SERVICE\_IS\_PARMS Parameters (cont.)

| Member                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nWaitHintMax</b>           | <p>Specifies the maximum dwWaitHint wait time (in milliseconds). If a service specifies a dwWaitHint longer than nWaitHintMax, nWaitHintMax is used instead as the wait time. This applies to both starting and stopping services.</p> <p>The default value of this member variable is 10000 (10 seconds), and is set by calling ServiceInitParams. See the MDSN documentation for more information on how a service sets dwWaitHint.</p>                                                                                                                                                                                                                                                                              |
| <b>nStartServiceWaitCount</b> | <p>Specifies the service start timeout in seconds. This value can be set to a specific value to force the installation to stop waiting after the specified interval regardless of whether the service has reached the desired state.</p> <div>  <p><b>Important</b> ■ Unlike nWaitHintMax, if a service specifies a long dwWaitHint, the installation does not interrupt this wait regardless of the value of this parameter. Therefore, it is recommended that this value not be changed from the default value of INFINITE set by ServiceInitParams. Instead, update nWaitHintMax to prevent an undesired wait interval.</p> </div> |
| <b>nStopServiceWaitCount</b>  | <p>Specifies the service stop timeout in seconds. This value can be set to a specific value to force the setup to stop waiting after the specified interval regardless of whether the service has reached the desired state.</p> <div>  <p><b>Important</b> ■ Unlike nWaitHintMax, if a service specifies a long dwWaitHint, the installation does not interrupt this wait regardless of the value of this parameter. Therefore, it is recommended that this value not be changed from the default value of INFINITE set by ServiceInitParams. Instead, update nWaitHintMax to prevent an undesired wait interval.</p> </div>       |

## Additional Information

For more information about the Windows API functions OpenSCManager, CreateService, or ChangeServiceConfig, consult the Windows API documentation.

# SERVICE\_IS\_STATUS

**Project** ■ This information applies to InstallScript projects.

When you call **ServiceGetServiceState**, this structured variable returns identification information about the service. This system variable is of type `SERVICE_IS_STATUS`; it has the following members:

**Table 2** • `SERVICE_IS_STATUS` Parameters

| Member                 | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dwServiceType</b>   | <p>The type of service. This member can be one of the following values.</p> <ul style="list-style-type: none"> <li>● <b>SERVICE_FILE_SYSTEM_DRIVER</b>—The service is a file system driver.</li> <li>● <b>SERVICE_KERNEL_DRIVER</b>—The service is a device driver.</li> <li>● <b>SERVICE_WIN32_OWN_PROCESS</b>—The service runs in its own process.</li> <li>● <b>SERVICE_WIN32_SHARE_PROCESS</b>—The service shares a process with other services.</li> </ul> <p>If the service type is either <code>SERVICE_WIN32_OWN_PROCESS</code> or <code>SERVICE_WIN32_SHARE_PROCESS</code>, the following type may also be specified.</p> <ul style="list-style-type: none"> <li>● <b>SERVICE_INTERACTIVE_PROCESS</b>—The service can interact with the desktop.</li> </ul> |
| <b>dwCurrentState</b>  | <p>The current state of the service. This member can be one of the following values.</p> <ul style="list-style-type: none"> <li>● <b>SERVICE_CONTINUE_PENDING</b>—The service continue is pending.</li> <li>● <b>SERVICE_PAUSE_PENDING</b>—The service pause is pending.</li> <li>● <b>SERVICE_PAUSED</b>—The service is paused.</li> <li>● <b>SERVICE_RUNNING</b>—The service is running.</li> <li>● <b>SERVICE_START_PENDING</b>—The service is starting.</li> <li>● <b>SERVICE_STOP_PENDING</b>—The service is stopping.</li> <li>● <b>SERVICE_STOPPED</b>—The service is not running.</li> </ul>                                                                                                                                                                 |
| <b>dwWin32ExitCode</b> | <p>A Win32 error code that the service uses to report an error that occurs when it is starting or stopping. To return an error code specific to the service, the service must set this value to <code>ERROR_SERVICE_SPECIFIC_ERROR</code> to indicate that the <code>dwServiceSpecificExitCode</code> member contains the error code. The service should set this value to <code>NO_ERROR</code> when it is running and on normal termination.</p>                                                                                                                                                                                                                                                                                                                   |

**Table 2** • SERVICE\_IS\_STATUS Parameters (cont.)

| Member                           | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dwServiceSpecificExitCode</b> | A service-specific error code that the service returns when an error occurs while the service is starting or stopping. This value is ignored unless the dwWin32ExitCode member is set to ERROR_SERVICE_SPECIFIC_ERROR.                                                                                                                                                                                                                                                                                                                                |
| <b>dwCheckPoint</b>              | A value that the service increments periodically to report its progress during a lengthy start, stop, pause, or continue operation. For example, the service should increment this value as it completes each step of its initialization when it is starting up. The user interface program that invoked the operation on the service uses this value to track the progress of the service during a lengthy operation. This value is not valid and should be zero when the service does not have a start, stop, pause, or continue operation pending. |
| <b>dwWaitHint</b>                | An estimate of the amount of time, in milliseconds, that the service expects a pending start, stop, pause, or continue operation to take before the service makes its next call to the Windows API function SetServiceStatus with either an incremented dwCheckPoint value or a change in dwCurrentState. If the amount of time specified by dwWaitHint passes, and dwCheckPoint has not been incremented, or dwCurrentState has not changed, the service control manager or service control program can assume that an error has occurred.           |
| <b>dwControlsAccepted</b>        | The control codes that the service will accept and process in its handler function. A user interface process can control a service by specifying a control command in the Windows API function ControlService. By default, all services accept the SERVICE_CONTROL_INTERROGATE value. Table 3 lists the possible control codes for this member.                                                                                                                                                                                                       |

## dwControlAccepted Control Codes

This table lists the possible control codes for dwControlAccept script variable.

**Table 3** • dwControlsAccepted Control Codes

| Control Code                        | Description                                                                                                                                                                                                                                                                                                              |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SERVICE_ACCEPT_NETBINDCHANGE</b> | <p>The service is a network component that can accept changes in its binding without being stopped and restarted.</p> <p>This control code allows the service to receive SERVICE_CONTROL_NETBINDADD, SERVICE_CONTROL_NETBINDREMOVE, SERVICE_CONTROL_NETBINDENABLE, and SERVICE_CONTROL_NETBINDDISABLE notifications.</p> |

**Table 3** ▪ dwControlsAccepted Control Codes (cont.)

| Control Code                         | Description                                                                                                                                                                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SERVICE_ACCEPT_PARAMCHANGE</b>    | <p>The service can reread its startup parameters without being stopped and restarted.</p> <p>This control code allows the service to receive SERVICE_CONTROL_PARAMCHANGE notifications.</p>                                                                              |
| <b>SERVICE_ACCEPT_PAUSE_CONTINUE</b> | <p>The service can be paused and continued.</p> <p>This control code allows the service to receive SERVICE_CONTROL_PAUSE and SERVICE_CONTROL_CONTINUE notifications.</p>                                                                                                 |
| <b>SERVICE_ACCEPT_SHUTDOWN</b>       | <p>The service is notified when system shutdown occurs.</p> <p>This control code allows the service to receive SERVICE_CONTROL_SHUTDOWN notifications. Note that the Windows API function ControlService cannot send this notification; only the system can send it.</p> |
| <b>SERVICE_ACCEPT_STOP</b>           | <p>The service can be stopped.</p> <p>This control code allows the service to receive SERVICE_CONTROL_STOP notifications.</p>                                                                                                                                            |

The dwControlAccept value can also contain the following extended control codes, which are supported only by service handler functions that are used with the Windows API function **RegisterServiceCtrlHandlerEx**.

**Table 4** ▪ Extended Control Codes for dwControlAccept

| Control Code                                | Description                                                                                                                                                                          |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SERVICE_ACCEPT_HARDWAREPROFILECHANGE</b> | <p>The service is notified when the computer's hardware profile has changed. This enables the system to send SERVICE_CONTROL_HARDWAREPROFILECHANGE notifications to the service.</p> |
| <b>SERVICE_ACCEPT_POWEREVENT</b>            | <p>The service is notified when the computer's power status has changed. This enables the system to send SERVICE_CONTROL_POWEREVENT notifications to the service.</p>                |
| <b>SERVICE_ACCEPT_SESSIONCHANGE</b>         | <p>Whistler: The service is notified when the computer's session status has changed. This enables the system to send SERVICE_CONTROL_SESSIONCHANGE notifications to the service.</p> |

# SUITE\_HOSTED

**Project** ▪ *This information applies to InstallScript projects.*

Use the SUITE\_HOSTED variable to determine whether the InstallScript installation is running as an InstallScript package in an Advanced UI or Suite/Advanced UI installation.

If the InstallScript installation is running as an InstallScript package in an Advanced UI or Suite/Advanced UI installation, SUITE\_HOSTED is set to a non-zero value. If SUITE\_HOSTED is set to zero, the InstallScript installation is not running as an InstallScript package in an Advanced UI or Suite/Advanced UI installation. For example:

```
if SUITE_HOSTED then
    // Code for an InstallScript installation that is run
    // as an InstallScript package in an Suite/Advanced UI
    // or Advanced UI installation
else
    // Code for an InstallScript installation that is run
    // standalone, not as an InstallScript package in an
    // a Suite/Advanced UI or Advanced UI installation
endif;
```

# Data Types and Predefined Structures

## Data Types

InstallScript supports the following data types. Note that some data types can be entered in either lowercase or uppercase letters:

**Table 1** • Data Types

| Data Type                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>binary</b><br><b>BINARY</b> | <p>Indicates binary data (specified in a string variable) to be passed to or retrieved from an external DLL function. Unlike the STRING or WSTRING data types, when the BINARY data type is specified, the InstallScript engine does not attempt to interpret the data as a string or perform any type of data conversion or validation; thus, this data type is used when passing binary data that may or may not consist of valid string characters.</p> <p>Note that this data type can be used only in a prototype of an external DLL function. If this data type is used for a variable instance or as a parameter for a non-DLL InstallScript function, compile error C8116 error occurs.</p> <p>If a standard InstallScript string is passed through the BINARY data type, the characters in the string are passed as ASCII characters. Therefore, the binary type is similar to the STRING data type, not the WSTRING data type, for valid string characters.</p> |
| <b>BOOL</b>                    | <p>Boolean data: either TRUE (1) or FALSE (0). Variables of this type should not be used to store any other values. Like C++, InstallScript evaluates non-zero values as TRUE; only the value of zero is evaluated as FALSE. Normally, the value of one is used to indicate TRUE.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>char</b><br><b>CHAR</b>     | <p>Character data: a single 8-bit signed character. When a literal character appears in a script, it must be enclosed within single or double quotation marks. Note that you can assign a numeric ASCII value to a character value. To display a char variable as a character, use the <a href="#">Format Specifiers</a> “%c” with the function <a href="#">SprintfBox</a>. To display the numeric value of a char variable use the specifier “%d”.</p> <p>InstallScript character variable types are signed; therefore extended ASCII characters will be interpreted as negative numbers when interpreted numerically. To avoid this problem, assign the value to a number variable; then AND (&amp;) the number variable with the value 255 before interpreting the number.</p>                                                                                                                                                                                         |
| <b>HWND</b>                    | <p>Handle to a window. The HWND variable type also can be used to store any other type of handle valid in Windows. HWND variables are normally initialized using the <a href="#">CmdGetHwndDlg</a> or <a href="#">GetWindowHandle</a> functions. Internally, HWND variables are equivalent to the data type NUMBER.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 1** • Data Types (cont.)

| Data Type                        | Description                                                                                                                                                                                                                                                                                                                               |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>int</b><br><b>INT</b>         | Equivalent to the number type; provided for convenience.                                                                                                                                                                                                                                                                                  |
| <b>LIST</b>                      | Pointer to an InstallScript list. LIST variables are always initialized and uninitialized using the <a href="#">ListCreate</a> and <a href="#">ListDestroy</a> functions. Internally, LIST variables are equivalent to the data type NUMBER.                                                                                              |
| <b>long</b><br><b>LONG</b>       | Equivalent to the NUMBER type; provided for convenience.                                                                                                                                                                                                                                                                                  |
| <b>LPSTR</b>                     | Equivalent to the POINTER type; provided for convenience.<br>For more information, see <a href="#">Pointers</a> .                                                                                                                                                                                                                         |
| <b>LPWSTR</b>                    | Equivalent to the WPOINTER type; provided for convenience.<br>For more information, see <a href="#">Pointers</a> .                                                                                                                                                                                                                        |
| <b>number</b><br><b>NUMBER</b>   | Signed four-byte integer. Number is the recommended data type for storing numeric data. The data type is similar to the LONG variable type of other programming languages. It can hold any value between -2,147,483,648 and +2,147,483,647. Note that all numeric data types in InstallScript are equivalent to the NUMBER variable type. |
| <b>object</b><br><b>OBJECT</b>   | A reference to a COM object. The reference is returned by the <a href="#">CreateObject</a> function and assigned to the object variable using the <a href="#">set</a> keyword.                                                                                                                                                            |
| <b>pointer</b><br><b>POINTER</b> | A pointer to data. In the case of a pointer to a string variable, the data pointed to is an ANSI string. Pointer variables are normally initialized by using the address-of (&) operator to assign the address of a variable to the pointer variable.<br>For more information, see <a href="#">Pointers</a> .                             |
| <b>short</b><br><b>SHORT</b>     | Equivalent to the NUMBER type; provided for convenience.                                                                                                                                                                                                                                                                                  |

**Table 1** • Data Types (cont.)

| Data Type                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>string</b><br><b>STRING</b>   | <p>An array of Unicode characters (two bytes per character). String variables, which are similar to arrays of characters in the C++ language, are NULL terminated. However, InstallShield does not support multiple NULL-terminated strings in the same string variable. String variables can be declared with an explicit size of up to 65,535 characters. Strings variables that are declared without an explicit size are automatically sized by InstallShield. Note that string concatenation in a setup script is performed by using the concatenation operator, which is a plus sign (+). Strings to be concatenated are positioned as operands on either side of the operator, as shown in the statement below, which appends the value of szLastName to the value of szFirstName and assigns the resulting string to szFullName:</p> <pre>szFullName = szFirstName + szLastName;</pre> <p>To display a string variable, use the <a href="#">SprintfBox</a> function with the format specifier “%s”, or use the <a href="#">MessageBox</a> function.</p>  <p><b>Note</b> • You can declare string variables as <i>STRING</i> in InstallScript code; string variables that are declared this way in InstallScript code are stored as Unicode strings in string tables. However, if you want to store Unicode strings in structures that are passed outside of the InstallScript code—for example, to a DLL function—you may need to use the <i>WSTRING</i> type when declaring the strings as structure members in your InstallScript code. For more information, see <a href="#">Data Structures</a>.</p> |
| <b>variant</b><br><b>VARIANT</b> | <p>Any kind of data: character, string, numeric, object reference, and so on. It is recommended that you use the other data types whenever possible; the VARIANT data type is necessary only when declaring a script-defined function that takes an array as an argument, for example:</p> <pre>prototype number AverageValue( variant );  function OnBegin( )     number nAverage , nArray(10); begin     /* Assign values to array elements here. */      /* Pass the array to the function. */     nAverage = AverageValue( nArray ); end;</pre> <p>Note that the VARIANT data type cannot be defined within a data structure.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 1** • Data Types (cont.)

| Data Type                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>void</b><br><b>VOID</b>         | <p>Void is not a true data type, in the sense that a variable cannot be declared as type void. Void is only used in function prototypes to indicate that the function does not return a value, as in the following:</p> <pre> prototype void Subroutine(int);  function void Subroutine(int); begin     // perform operations, but     // do not return a value end;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>wpointer</b><br><b>WPOINTER</b> | <p>A pointer to string data. The POINTER type should be used in all cases except when a pointer to Unicode string data is needed. Pointer variables are normally initialized by using the address-of (&amp;) operator to assign the address of a variable to the pointer variable.</p> <p>For more information, see <a href="#">Pointers</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>wstring</b><br><b>WSTRING</b>   | <p>Same as STRING except that, unlike STRING, it can be used when declaring DLL function calls in which a wide-character string argument or Unicode string argument is expected. For example:</p> <pre> prototype long Kernel32.GetWindowsDirectoryW(BYREF wstring, int);</pre> <p>You can pass a string variable in a WSTRING argument; for example:</p> <pre> wstring svWinDir; ... GetWindowsDirectoryW(svWinDir, 1024);</pre> <div data-bbox="631 1236 669 1281" data-label="Image"></div> <p><b>Note</b> • You can declare string variables as <i>STRING</i> in <i>InstallScript</i> code; string variables that are declared this way in <i>InstallScript</i> code are stored as Unicode strings in string tables. However, if you want to store Unicode strings in structures that are passed outside of the <i>InstallScript</i> code—for example, to a DLL function—you may need to use the <i>WSTRING</i> type when declaring the strings as structure members in your <i>InstallScript</i> code. For more information, see <a href="#">Data Structures</a>.</p> |

**Note** • *InstallScript* does not provide unsigned or floating-point data types.

## Predefined Structures

InstallScript supports the following predefined structures:

**Table 2** • Predefined Structures

| Predefined Structure       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>_FONTFILEINFO</b>       | <p>This is a data structure that is passed to the <a href="#">OnInstalledFontFile</a> and <a href="#">OnUninstallingFontFile</a> event handlers. It has the following members:</p> <ul style="list-style-type: none"> <li>● <b>string szFileName[_MAX_PATH]</b>—The complete path to the font file being installed on the system</li> <li>● <b>string szFaceName[_MAX_PATH]</b>—The face name of the font being installed (if you specify the name for the font file in InstallShield)</li> </ul> <p>Note that the information in the structure is passed to the event handler so that the event handler can use the information. Thereafter, the values of the structure are used by the installation. Therefore, changing the structure members does not have any effect on the installation.</p>                                                                                                                                                                                     |
| <b>_LAAW_PARAMETERS</b>    | For a list of this data structure's members and their purposes and permitted values, see <a href="#">LAAW_PARAMETERS</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>_SERVICE_IS_PARAMS</b>  | For a list of this data structure's members and their purposes and permitted values, see <a href="#">SERVICE_IS_PARAMS</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>_SERVICE_IS_STATUS</b>  | For a list of this data structure's members and their purposes and permitted values, see <a href="#">SERVICE_IS_STATUS</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ISURL_COMPONENTS</b>    | <p>This is a data structure that contains the constituent parts of a URL. This structure is similar to the Windows API structure URL_COMPONENTS. For an example of the use of this structure, see <a href="#">ParseUrl</a>. This structure has the following members:</p> <ul style="list-style-type: none"> <li>● <b>szScheme</b>—String value that contains the scheme name.</li> <li>● <b>nInternetScheme</b>—Numeric value that indicates the Internet protocol scheme; equals 3 for HTTP and 4 for HTTPS.</li> <li>● <b>szUserName</b>—String value that contains the user name.</li> <li>● <b>szPassword</b>—String value that contains the password.</li> <li>● <b>szHostName</b>—String value that contains the host name.</li> <li>● <b>nInternetPort</b>—Port number.</li> <li>● <b>szUrlPath</b>—String value that contains the URL path.</li> <li>● <b>szExtraInfo</b>—String value that contains the extra information (for example, ?something or #something).</li> </ul> |
| <b>PROCESS_INFORMATION</b> | For a list of this data structure's members and their purposes and permitted values, see <a href="#">LAAW_PROCESS_INFORMATION</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 2** • Predefined Structures (cont.)

|----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>STARTUPINFO</b>   | For a list of this data structure's members and their purposes and permitted values, see <a href="#">LAAW_STARTUPINFO</a> . |

## Arrays

You can declare and use any InstallScript data type as an array. To declare a variable as an array, append an open parenthesis and a close parenthesis, with an array size optionally between the parentheses, to the variable name in the declaration. For example, the following declares a variable called `nArray` to be an array containing 10 `NUMBER` elements:

```
NUMBER nArray(10);
```

If you do not declare an array size, for example,

```
NUMBER nArray( );
```

the array size defaults to zero. You can resize arrays in the script by using the `Resize` operator. You can get the size of an array by using the `SizeOf` operator.

Use the following syntax to assign values to array elements:

### Syntax

```
<array variable name>(<array index>) = <value>;
```

For example:

```
nArray(0) = 1; /* Array indexing begins with zero. */
nArray(5) = 17;
```

When declaring a script-defined function that takes an array as an argument, do not use an array as the parameter data type; for example:

```
prototype NUMBER AverageValue( NUMBER( ) ); /* This will not compile. */
```

Instead, use the `VARIANT` data type; for example:

```
prototype NUMBER AverageValue( VARIANT );

function OnBegin( )
    NUMBER nAverage, nArray(10);
begin
    /* Assign values to array elements here. */

    /* Pass the array to the function. */
    nAverage = AverageValue( nArray );
end;
```

## Constant Data

A constant is a named data item with a defined value. InstallShield supports two types of constants:

- Predefined constants, such as TRUE and RESET, are part of InstallScript. These constants, which are used as function parameters and return values for built-in functions, cannot be redefined in the script. Attempting to redefine a predefined constant results in a compiler error.
- User-defined constants are declared by the programmer as needed for individual scripts. Although a user-defined constant can be redefined after the initial declaration, it is generally not considered good programming practice to do so.

User-defined constants are declared with a `#define` preprocessor statement. (InstallScript does not support the `const` keyword for declaring variable constants as the C++ language does.) String constants must be enclosed within quotation marks; numeric constants are defined without quotation marks and contain only numeric characters. Once declared, a string constant can be used anywhere that a string literal can be used. Likewise, number constants can be used anywhere that a numeric literal can be used.

In the following example, a string constant and a numeric constant are declared:

```
#define COMPANY_NAME "Example_Company"
#define MAXCOUNT    1000
```

A constant name must follow the rules for InstallScript identifiers. By convention, constant identifiers are created with all uppercase characters. InstallScript's predefined constants follow that convention.

## Data Structures

A data structure is a named data item that consists of logically related variables, called members. In many programming languages, data structures are called records, and the variables within records are called fields. In InstallScript, data structures are similar in form and function to structures in C. They can include members of different data types, and those members within the data structure can be referenced directly by using the [member operator \(.\)](#).

### Defining a Data Structure

To define a data structure, use the keyword `typedef` and follow it with the name of the data structure. Fields in the structure must be defined within a `begin...end` block, as shown in the example below, which defines a structure called `EMPLOYEE`. The data structure `EMPLOYEE` includes three variables: a string variable for an employee's name, a string variable for an employee's department, and a number variable for an employee's phone extension.

```
typedef EMPLOYEE
begin
    STRING szName[50];
    STRING szDepartment[50];
    NUMBER nExtension;
end;
```

When you define a data structure, you are actually defining a new data type. To use a data structure within a program, you must first declare a variable of that type. To do that, use the name of the defined data structure as the data type and follow it with an identifier, as shown in the example below, which creates a variable of type `EMPLOYEE`.

```
EMPLOYEE structEmployee;
```

To reference members of the structure variable, use the member operator ( `.` ). In the example below, literal values are assigned to each member of `structEmployee`.

```
structEmployee.szName = "I. S. Coder";
structEmployee.szDepartment = "Development";
structEmployee.nExtension = 555;
```

## Restrictions

The following restrictions apply to structures:

- You cannot assign the contents of one structure to another structure with the assignment operator, as in `newstruct = struct1`. Instead, you must copy the structure one element at a time.
- You must specify the size of all STRING declarations in a structure—the autosizing functionality in `InstallScript` does not work in `typedef` statements.
- You cannot declare a structure within a function.
- You cannot use the BYREF operator with a structure, nor can you pass a structure member in a parameter that was declared with the BYREF operator. To modify a member of a user-defined structure in a user-defined function, pass a pointer to the structure and then use the [Structure Pointer Operator \(->\)](#) to access the data within the function.
- Referencing a pointer before the address of a data structure has been assigned to the pointer results in a run-time error.

## Unicode Support for Structures

Structures in `InstallScript` can contain any basic data type, including strings and pointers, or other structures. If a structure needs to contain a Unicode string and the structure is passed to an external DLL, the `InstallScript` engine can distinguish between string member types in a structure, and then size the structure and calculate member offsets correctly. String members that need to be stored and passed as Unicode can be declared with the `WSTRING` type.

Note that if a Unicode string is declared with the `STRING` type and the string is used in a structure, the `InstallScript` engine treats the string as ANSI when passing it to an external DLL. As a result, the size of the structure and member offsets in the structure could be wrong, causing the DLL to incorrectly read or write data related to the structure.

Pointer members in structures can be declared as `WPOINTER`. This enables you to store pointers to Unicode strings in a structure.

## Examples

Like C, `InstallScript` allows you to nest or embed data structures. For example, suppose you wanted to create a structure that could be used to define the upper-left and lower-right coordinates of a rectangle. Each coordinate consists of two values: an x value and a y value. You could define a structure that consists of four members: the x and y positions of the upper-left corner and the x and y positions of the lower-right corner.

However, since each x and y pair is a logical unit, you might first define a structure called `POINT` that has two members defining a vertical and horizontal position. Then you could define a structure called `RECT` that includes two members of type `POINT`, one to define the upper left coordinate, another to define the lower right coordinate. These two structures are shown below:

```
// Define a point structure.
typedef POINT
begin
    SHORT nX;
```

```

        SHORT nY;
    end;

    // Use nested point structures to define a rectangle structure.
    typedef RECT
    begin
        POINT UpperLeft;
        POINT LowerRight;
    end;

```

When a structure is to be referenced by a pointer to that structure, you must use the structure pointer operator ( - > ) to address members of the structure. In the example below, a variable of type RECT is declared, a pointer to the structure is declared, and then the address of the RECT variable is assigned to the pointer. Finally, the structure pointer operator is used to initialize each member to 0.

```

RECT Rectangle;
RECT POINTER pRect;

pRect = &Rectangle;
pRect->UpperLeft.nX = 0;
pRect->UpperLeft.nY = 0;
pRect->LowerRight.nX = 0;
pRect->LowerRight.nY = 0;

```

The following script presents a more complete demonstration of structure pointers, nested structures, and structure pointer dereferencing with the structure pointer operator.

```

// Use a structure to define a point.
typedef POINT
begin
    SHORT nX;
    SHORT nY;
end;

// Use nested structures to define a rectangle.
typedef RECT
begin
    POINT UpperLeft;
    POINT LowerRight;
end;

// Declare a rectangle structure variable.
RECT Rectangle;

// Define a pointer to a RECT structure.
RECT POINTER pRect;

// Declare a function to display structure contents.
prototype ShiftRectBy2(RECT POINTER);

. . .

// Get a pointer to the Rectangle structure.
pRect = &Rectangle;

// Define the points that define the rectangle.
pRect->UpperLeft.nX = 100;

```

```

pRect->UpperLeft.nY = 400;
pRect->LowerRight.nX = 200;
pRect->LowerRight.nY = 100;

// Display point x and y values before calling ShiftRectBy2.
sprintfBox (INFORMATION,
    "BEFORE calling ShiftRectBy2",
    "pRect->UpperLeft.nX = %d\n" +
    "pRect->UpperLeft.nY = %d\n" +
    "pRect->LowerRight.nX = %d\n" +
    "pRect->LowerRight.nY = %d\n",
    pRect->UpperLeft.nX,
    pRect->UpperLeft.nY,
    pRect->LowerRight.nX,
    pRect->LowerRight.nY
);

// Shift the rectangle 2 up and 2 to the right.
ShiftRectBy2(pRect);

// Display point x and y values after calling ShiftRectBy2.
sprintfBox (INFORMATION,
    "AFTER calling ShiftRectBy2",
    "pRect->UpperLeft.nX = %d\n" +
    "pRect->UpperLeft.nY = %d\n" +
    "pRect->LowerRight.nX = %d\n" +
    "pRect->LowerRight.nY = %d\n",
    pRect->UpperLeft.nX,
    pRect->UpperLeft.nY,
    pRect->LowerRight.nX,
    pRect->LowerRight.nY
);

// Define the rectangle shifting function.
function ShiftRectBy2(pR)
begin
    pR->UpperLeft.nX = pR->UpperLeft.nX + 2;
    pR->UpperLeft.nY = pR->UpperLeft.nY + 2;
    pR->LowerRight.nX = pR->LowerRight.nX + 2;
    pR->LowerRight.nY = pR->LowerRight.nY + 2;
end;

```

## Language IDs

InstallShield provides language constants for all languages supported by Windows. However, most of these constants are not supported for the designation of language-specific components and language filtering.

InstallScript constants can be used in the following contexts.

## Parameter for FeatureFilterLanguage

InstallScript language constants are used as the second parameter to the function `FeatureFilterLanguage`. In this context, the language constant specifies which files to filter or unfilter. Only supported language constants, which are listed in the supported language table should be used for this purpose. Using an unsupported language constant for component filtering has no effect since components designated for an unsupported language are filtered (not included) during the media build and so cannot be installed.

## Return Value for GetSystemInfo

A language constant serves as the value returned in `nvResult` by function `GetSystemInfo` when it is called with the constant `LANGUAGE` in the `nltem` parameter. In this context, any of the language constants that are listed in `ISRTDefs.h` can be returned because Windows supports all the language constants.

---

**Note** ▪ If your installation includes language filtering based on these return values, you must use a switch statement to convert constants returned by this function into one of the constants supported for language filtering.

## Language Constant Reference

For a complete list of language constants that are supported by InstallShield, as well as their numeric equivalents, refer to the file `ISRTDefs.h`, which is located in the `Script\Include` folder within the InstallShield Program Files folder.

For a list of supported languages and the appropriate InstallScript constants, see [Language Support for InstallScript](#).

---

**Note** ▪ The language that the setup is using to display prompts and messages is stored in the system variable `SELECTED_LANGUAGE`.

When the language selection dialog is used by a multilanguage installation to allow the end user to select the installation language during setup initialization, the language dialog will display the Windows equivalent names. Because these names are generated by Windows, they will be localized to the version of Windows under which the installation is being run.

# Pointers

A pointer is a variable that contains the address of another variable. To declare a pointer, use the keyword `POINTER` or `WPOINTER` followed by a variable name, as shown in the following two sample lines of code:

```
POINTER pPointerName;
WPOINTER pwPointerName;
```

To declare a pointer that will be used to access the members of a data structure, precede the keyword `POINTER` or `WPOINTER` with the structure type:

```
typedef RECT
begin
    SHORT sX;
    SHORT sY;
```

```

end;

RECT Rectangle;

RECT POINTER pRect;

```

Use the address operator (&) to assign the address of a variable to a pointer variable:

```

pPointerName = &MyStructure;
pNum = &nvNumber;
pString = &svString;

```

When you are defining a function that takes a pointer to a structure as a parameter, use the structure name with `POINTER` or `WPOINTER` in the function prototype, as shown below. Note that any function prototype that specifies a pointer to a structure as one of its parameters must be declared after the structure declaration.

```

typedef RECT
begin
    SHORT sX;
    SHORT sY;
end;

RECT Rectangle;
RECT POINTER pRect;

prototype SizeRectangle(RECT POINTER);

. . .

pRect = &Rectangle;
SizeRectangle(pRect);

. . .

function SizeRectangle(pRectangle)
begin
    pRectangle->sX = 10;
    pRectangle->sY = 5;
end;

```

## Passing Pointers to Strings to Functions that Are Implemented Outside InstallScript Code

The InstallScript compiler lets you pass pointers to Unicode or ANSI strings to functions that are implemented outside script. For example, if you want to call a DLL function that accepts pointers to strings in its parameters, the DLL function prototype would look something like the following in C or C++:

```
void __stdcall MyDllFunction(LPCSTR pszString);
```

In InstallScript, the function could be prototyped as follows:

```
prototype DLL.MyDllFunction(POINTER);
```

You can use the address-of operator (&) to call the function and pass a pointer to a string:

```
DLL.MyDllFunction(&myString);
```

When the script engine makes this function call, the data in string **myString** is passed through a pointer value to **MyDllFunction**. **MyDllFunction** receives a pointer to an ANSI representation of the string that is contained in **myString**.

The pointer type **WPOINTER** (or optionally **wpointer** or **LPWSTR**) lets you pass pointers to Unicode strings to functions outside of script. For example, if the DLL uses Unicode strings, you could change its prototype in C or C++ to the following:

```
void __stdcall MyDllFunction(LPCWSTR pszString);
```

In **InstallScript**, the only change that is required to pass a Unicode string pointer to a DLL that uses Unicode strings is the prototype, which would contain the **WPOINTER** type, as follows:

```
prototype DLL.MyDllFunction(WPOINTER);
```

When the DLL function is called in the running script, the engine passes a pointer to a Unicode copy of the string that is stored in **myString** instead of an ANSI version.

## Using **STRING** and **WSTRING** Instead of Pointers

In most cases, you do not need to use pointers to pass strings to external DLL functions. The **STRING** and **WSTRING** types may be used in place of **POINTER** or **WPOINTER**. If a DLL function expects an ANSI string, you can use the **STRING** type; if a DLL function expects a Unicode string, you can use the **WSTRING** type. Using **BYREF** and **BYVAL** will allow for passing a string that either can be modified by the external DLL function or not.

Thus, if you use the following prototype for the function, an ANSI string could be passed by value or by references (modifying the prototype to **BYREF** as needed):

```
prototype DLL.MyDllFunction(byval string);
```

Changing the parameter type to **BYVAL WSTRING** allows a Unicode version of the string to be passed instead of the ANSI version.

# Variable Data

A variable is a named data item whose value can change during program execution.

## Variable Declaration

### Format

A variable must be declared in the following format:

```
data_type  VariableName1[, VariableName2 [,...]];
```

### Rules

Variable declaration must follow these rules:

- A variable name can have a maximum of 32 characters.
- When more than one variable name is specified in a single declaration, the names must be separated by commas.
- Each variable declaration must be terminated with a semicolon.

**Caution** ▪ The names of InstallScript variables and functions are case sensitive. For example, `svItemCounter` is not equivalent to `svITEMCOUNTER`.

## Variable Declaration Example

In the following example, seven variables are declared. Note that the last declaration creates three numeric variables.

```
BOOL bValidEntry;

LONG lPopulation;

//String explicitly sized
STRING szUserName[128];

//String autosized
STRING szMessage;

NUMBER nFileSize, nDirSize, nDiskSpace;
```

## Declaring String Variables

You can declare a string variable with or without an explicit size. String variables that are not declared with an explicit size are then sized automatically during a setup to accommodate the values assigned to them. Autosizing is recommended for all string variables except those that will be passed to an external (DLL or Windows API) function—in these cases, the string's size *must* be declared explicitly. The maximum size of a string is 65534 characters.

# Global vs. Local Variables

Variables may be either global or local:

- A variable is global if it is declared outside of the main program block and not within a function. Global variables are visible and available to all statements in a setup script that follow its declaration.
- A variable is local if it is declared between the function declaration and the keyword *begin* within that function. Local variables are visible and available only within the function where they are declared.

---

**Project** ▪ *InstallScript events are not used in Basic MSI and merge module projects; therefore, all InstallScript code for these project types must be written in InstallScript custom actions. Global variables do not share state between these custom action invocations.*

---

**Note** ▪ *InstallScript system variables are global and therefore are visible to the main program and to all functions in a script.*

In the following example, the variable `nVisibleEverywhere` can be referenced by any statement in the script. The variable `nVisibleOnlyToFunctions` may be referenced only by the functions. The variable `nVisibleOnlyToSecondFunction` cannot be referenced by the main program or by `FirstFunction`. The variable `szString` is local to `FirstFunction`.

```

prototype FirstFunction();
prototype SecondFunction();

NUMBER nVisibleEverywhere;

. . .

nVisibleEverywhere = 10;

FirstFunction();
SecondFunction();

. . .

NUMBER nVisibleOnlyToFunctions;

function FirstFunction()
    STRING szString;
begin
    szString = "Local to FirstFunction";
    nVisibleOnlyToFunctions = 20;
end;

    NUMBER nVisibleOnlyToSecondFunction;

function SecondFunction()
begin
    nVisibleOnlyToSecondFunction = 30;
end;
```

Although identifiers in a script must be unique, it is valid for a local variable to have a name identical to that of a global variable, or for one function to declare a local variable that has the same name as a local variable declared in another function. These exceptions are allowed because InstallShield qualifies local variable names based on the function with which they are associated. In the example below, the global variable `szVal` is not affected by the action of `AFunction`, which has a local variable of the same name; the function `MessageBox` displays the string “YES,” which was the value assigned to the global variable `szVal`.

```

    STRING szVal;

    prototype AFunction();

    . . .

    szVal = "YES";
    AFunction();
    MessageBox(szVal, INFORMATION);

    . . .

function AFunction()
    STRING szVal;
begin
    szVal = "NO";
end;
```

Parameter names in function definitions are considered to be local variables. If a global variable is passed to a function whose parameter has the same name as the global variable, the value of that global variable will not be changed (unless the parameter was specified with the `BYREF` operator in the function prototype). In the following example, `AFunction` has no effect on the global variable `szVal`; the script displays the string “YES”.

```

    STRING szVal;
    prototype AFunction(STRING);

    . . .

    szVal = "YES";
    AFunction(szVal);
    MessageBox(szVal, INFORMATION);

    . . .

function AFunction(szVal)
begin
    szVal = "NO";
end;
```

## String Variables

For information about string variables, refer to the following topics:

- [String Indexing](#)
- [String Size and Autosize](#)

## String Indexing

A string variable is an array of Unicode characters with a null terminator. You can reference individual characters within a string by specifying the string name followed by an index value within square brackets. Note that the first character in a string is in position 0.

In the example below, the function `BlankLeadingZeros` uses the string indexing technique to replace leading zeros in the string representation of a number with blank characters.

```

        prototype BlankLeadingZeros(BYREF STRING);

function BlankLeadingZeros(szString)
    INT iVal, iLength;
begin
    iVal = 0;
    iLength = StrLength (szString);

    while (szString[iVal] = "0") && (iVal <= iLength)
        szString[iVal] = " ";
        iVal++;
    endwhile;
end;
```

## String Size and Autosize

### InstallShield Autosizing

When you declare a string variable without a size specification, InstallShield automatically sizes a string buffer for that variable. The allocation for the buffer occurs when you first assign a string to the variable. If later, you assign a longer string to that variable, InstallShield increases the memory allocation to accommodate the longer string—up to the amount of available memory. However, if you later assign a shorter string to an autosized variable, InstallShield does not decrease the memory allocation.

**Caution** - InstallShield's autosizing feature does not work in typedef statements; you must specify the size of all `STRING` declarations in a structure.

### Specifying a String Size

When specifying a string size, you must declare one character position for the null terminator. For example, if you want your string to hold up to 128 characters, you must declare it with a length of 129 to allow room for the null terminator. For this reason, the minimum size of a string is 2.

When you are using a string that you have declared with a size, you must be aware of how that string might be used with other strings. For example, consider the following function call:

```

        STRING szQuestion[20], szDefault[20], svResult[50];

begin
    szQuestion = "Enter company name";
    szDefault  = "My Software Company";
    AskText (szQuestion, szDefault, svResult);
```

The size of the string `svResult` should be greater than or equal to the size of the string `szDefault`. If not, then `szDefault`, if accepted, will not fit into the `svResult` variable returned by the function. The easiest way to avoid conflicts is to let InstallShield autosize all strings (except those in a typedef statement).

---

**Caution** ▪ *An autosized string variable that is passed by reference to a function is not autosized within the called function. If the function attempts to assign a value whose length is greater than the current size of that parameter, run-time error 401 occurs.*

## System Variables

System variables are predefined script variables that contain information such as the source path, the target path, the Windows folder, and the Windows system folder. The installation automatically initializes these system variables when the installation process begins, and it is not necessary to declare these variables in your script.

---

**Project** ▪ *Many Windows Installer directory properties—such as `INSTALLDIR`, `AppDataFolder`, and `TempFolder`—are available directly as variables in your `InstallScript` code for Basic MSI and `InstallScript` MSI projects.*

### System Variables and Text Substitutions

Some of the system variables have corresponding text substitutions. The installation internally uses text substitution to set the values of certain system variables as shown in the following tables. You can use these text substitutions in your script in the same way that you use text substitutions that you have defined.

## Writable System Variables and Text Substitutions

**Table 1** • Writable System Variables and Text Substitutions

| Script Variable                      | Corresponding Text Substitution | Comments                                                                                                                                                                                                                                                    |
|--------------------------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ALLUSERS</b>                      | <PERUSER_INSTALL>               |                                                                                                                                                                                                                                                             |
| <b>DISK1TARGET</b>                   | <DISK1TARGET>                   |                                                                                                                                                                                                                                                             |
| <b>IFX_COMPANY_NAME</b>              | <IFX_COMPANY_NAME>              | <p>If this text substitution is defined in an object script, it applies to only that object, not to the main installation or any other objects in the installation.</p> <p>If it is defined in the main installation, it does not apply to any objects.</p> |
| <b>IFX_INSTALLED_DISPLAY_VERSION</b> | <IFX_INSTALLED_DISPLAY_VERSION> | <p>If this text substitution is defined in an object script, it applies to only that object, not to the main installation or any other objects in the installation.</p> <p>If it is defined in the main installation, it does not apply to any objects.</p> |
| <b>IFX_INSTALLED_VERSION</b>         | <IFX_INSTALLED_VERSION>         | <p>If this text substitution is defined in an object script, it applies to only that object, not to the main installation or any other objects in the installation.</p> <p>If it is defined in the main installation, it does not apply to any objects.</p> |
| <b>IFX_MULTI_INSTANCE_SUFFIX</b>     | <IFX_MULTI_INSTANCE_SUFFIX>     |                                                                                                                                                                                                                                                             |
| <b>IFX_PRODUCT_DISPLAY_NAME</b>      | <IFX_PRODUCT_DISPLAY_NAME>      | <p>If this text substitution is defined in an object script, it applies to only that object, not to the main installation or any other objects in the installation.</p> <p>If it is defined in the main installation, it does not apply to any objects.</p> |

**Table 1** • Writable System Variables and Text Substitutions (cont.)

| Script Variable                    | Corresponding Text Substitution   | Comments                                                                                                                                                                                                                                                    |
|------------------------------------|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IFX_PRODUCT_DISPLAY_VERSION</b> | <IFX_PRODUCT_DISPLAY_VERSION<br>> | <p>If this text substitution is defined in an object script, it applies to only that object, not to the main installation or any other objects in the installation.</p> <p>If it is defined in the main installation, it does not apply to any objects.</p> |
| <b>IFX_PRODUCT_KEY</b>             | <IFX_PRODUCT_KEY>                 | <p>If this text substitution is defined in an object script, it applies to only that object, not to the main installation or any other objects in the installation.</p> <p>If it is defined in the main installation, it does not apply to any objects.</p> |
| <b>IFX_PRODUCT_NAME</b>            | <IFX_PRODUCT_NAME>                | <p>If this text substitution is defined in an object script, it applies to only that object, not to the main installation or any other objects in the installation.</p> <p>If it is defined in the main installation, it does not apply to any objects.</p> |

## ADDREMOVE

**Project** ▪ This information applies to InstallScript projects.

The ADDREMOVE system variable is set equal to a non-zero value if the setup is run from Add or Remove Programs in the Control Panel and is set equal to FALSE otherwise. This system variable is read-only; if you attempt to assign a value to it, a compiler error results.

## ADDREMOVE\_COMBINEDBUTTON

**Project** ▪ This information applies to InstallScript projects.

This system variable's value is used by the MaintenanceStart function to specify the existence of and data in the application uninstallation registry key's ModifyPath and UninstallString values, so as to specify whether the application's Add or Remove Programs entry displays separate Change and Remove buttons or a combined Change/Remove button. For more information on this variable, see [MaintenanceStart](#).

This system variable is initialized to FALSE.

## ADDREMOVE\_HIDECHANGEOPTION

**Project** ▪ This information applies to InstallScript projects.

This system variable's value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's ModifyPath, NoModify, and UninstallString values. The NoModify registry value specifies whether a Change button is displayed for the application in Add or Remove Programs in the Control Panel. The ModifyPath and UninstallString registry values specify the behaviors of the Change and Remove buttons.

This system variable is initialized based on the value that you specify in the Disable Change Button setting in the General Information view.

## ADDREMOVE\_HIDEREMOVEOPTION

**Project** ▪ This information applies to InstallScript projects.

This system variable's value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's ModifyPath, NoRemove, and UninstallString values. The NoRemove registry value specifies whether a Remove button is displayed for the application in Add or Remove Programs in the Control Panel. The ModifyPath and UninstallString registry values specify the behaviors of the Change and Remove buttons.

This system variable is initialized based on the value that you specify in the Disable Remove Button setting in the General Information view.

## ADDREMOVE\_STRING\_REMOVEONLY

**Project** ▪ This information applies to InstallScript projects.

This system variable's value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's UninstallString value, which specifies the behavior of the Remove button (if any) in the application's Add or Remove Programs entry. For more information on this variable, see [MaintenanceStart](#).

This system variable is initialized to the string value "-removeonly".

## ADDREMOVE\_SYSTEMCOMPONENT

**Project** ▪ This information applies to InstallScript projects.

This system variable's value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's SystemComponent value, which specifies whether an entry is displayed for the application in Add or Remove Programs in the Control Panel.

This system variable is initialized to FALSE, meaning that an entry is displayed.

## ALLUSERS

The ALLUSERS system variable is the key to installations that allow installing the application to the current user or all users on the target system. The value of ALLUSERS determines the following:

- The root key that is used by registry functions that are called after RegDBSetDefaultRoot(HKEY\_USER\_SELECTABLE) is called
- The root key under which the application uninstallation key is created
- The location of registry entries that are specified in a registry set's HKEY\_USER\_SELECTABLE root key
- The value of the **DISK1TARGET** system variable (which specifies the path to the folder in which copies of certain installation files are placed to enable maintenance installations and uninstallation)
- The default value of the **TARGETDIR** system variable that is set by the default OnFirstUIBefore code
- Whether a shortcut that is defined in InstallShield with its Type property set to Automatic appears in the list of personal shortcuts or common shortcuts when the shortcut is created
- The default option selection in the **SdCustomerInformation** and **SdCustomerInformationEx** dialogs

ALLUSERS has no effect on the registration of COM DLL files.

The following sections explain how the value of ALLUSERS is determined and set in different project types.

### InstallScript Installations

If an installation is running as a first-time installation, the InstallScript engine determines during initialization the most appropriate value for the ALLUSERS variable and initializes it to that value:

- If the user does not have administrator privileges, ALLUSERS is set to 0. This results in a per-user installation.
- Otherwise, ALLUSERS is set to 1. This results in a per-machine installation by default.

If an installation is running in maintenance mode, the InstallScript engine determines the value of the ALLUSERS variable based on whether the initial installation was installed as per-user or per-machine (based on the location of where the uninstallation information was installed).

For an example of an InstallScript installation that allows installing the application to the current user or all users on the target system, see the sample project in the ALLUSERS Sample Project folder. This folder is a subfolder in the Samples folder of your InstallShield Program Files folder. The default location is:

C:\Program Files\InstallShield\2022\Samples\InstallScript\ALLUSERS Sample Project

## InstallScript Custom Actions in Basic MSI and InstallScript MSI Installations

### Getting the Value of the ALLUSERS Variable

The ALLUSERS InstallScript variable is determined by querying the Windows Installer property ALLUSERS:

**Table 3** • Getting the Value of the ALLUSERS InstallScript Variable

| Windows Installer Property | InstallScript Variable                                                | Notes                                                                                                   |
|----------------------------|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| ""                         | 0                                                                     | Any per-user or per-machine dependent script code in the custom action results in per-user behavior.    |
| 1                          | 1                                                                     | Any per-user or per-machine dependent script code in the custom action results in per-machine behavior. |
| Any other value            | The InstallScript engine attempts to determine the appropriate value. |                                                                                                         |

If the Windows Installer property ALLUSERS cannot be determined because the InstallScript engine determines that a deferred custom action is running, an unexpected property value is returned, or **MSiGetProperty** returns an error value. Therefore, the InstallScript engine attempts to determine the best value for the variable.

Note that the InstallScript engine uses **MsiGetMode** with the MSIRUNMODE\_SCHEDULED, MSIRUNMODE\_ROLLBACK, and MSIRUNMODE\_COMMIT flags to determine if a deferred custom action is running. If **MsiGetMode** returns true for any of the above values, the custom action is assumed to be deferred and the InstallScript mechanism is used.

Note that if a Basic MSI installation does not have a value for ALLUSERS in the Property table, any InstallScript custom action that runs before the installation displays an ALLUSERS dialog (such as the CustomerInformation dialog, which sets the ALLUSERS Windows Installer property) has the ALLUSERS InstallScript variable set to 0. Therefore, the InstallScript custom action exhibits per-user behavior. Thus, it is recommended that all Basic MSI installations have a default value for ALLUSERS in the Property table.

### Setting the Value of the ALLUSERS Variable

When the ALLUSERS InstallScript variable is set in script, the InstallScript engine first determines whether the platform and privilege level allow the ALLUSERS InstallScript variable to be changed. (In scenarios where the end user is not an administrator or power user, ALLUSERS cannot be changed.)

If the ALLUSERS InstallScript variable can be changed, the InstallScript engine attempts to update the ALLUSERS Windows Installer property appropriately as follows:

**Table 4** • Setting the Value of the ALLUSERS InstallScript Variable

| InstallScript Variable | Windows Installer Property |
|------------------------|----------------------------|
| 1                      | 1                          |

**Table 4** • Setting the Value of the ALLUSERS InstallScript Variable (cont.)

| InstallScript Variable | Windows Installer Property |
|------------------------|----------------------------|
| 0                      | ""                         |

Note that the InstallScript engine sets the ALLUSERS InstallScript variable even if the Windows Installer property cannot be set. This could result in synchronization problems between the Windows Installer property and the InstallScript variable. Therefore, if you change the ALLUSERS InstallScript variable in a custom action, it is recommended that you set the Windows Installer property manually as well to ensure that the property can be changed successfully.

The following table shows the behavior for various scenarios on Windows Vista with User Account Control (UAC) enabled.

**Table 5** • ALLUSERS Value on Windows Vista with UAC Enabled

| Type of Custom Action                                                                         | Manifest          | ALLUSERS Value in Property Table | Windows Installer Property | Resulting InstallScript Variable | Notes                                                                                             |
|-----------------------------------------------------------------------------------------------|-------------------|----------------------------------|----------------------------|----------------------------------|---------------------------------------------------------------------------------------------------|
| <b>Immediate</b>                                                                              | Highest available | 2                                | 1                          | 1                                |                                                                                                   |
| <b>Immediate</b>                                                                              | Invoker           | 2                                | ""                         | 0                                | The InstallScript variable cannot be changed. Per-machine InstallScript actions are not possible. |
| <b>Immediate</b>                                                                              | Highest available | 1                                | 1                          | 1                                |                                                                                                   |
| <b>Immediate</b>                                                                              | Invoker           | 1                                | 1                          | 1                                | The InstallScript variable cannot be changed. Per-machine InstallScript actions fail.             |
| <b>Immediate, before CustomerInformation dialog (or end user selects to install per user)</b> | Invoker           | ""                               | ""                         | 0                                | The InstallScript variable cannot be changed. Per-machine InstallScript actions are not possible. |
| <b>Immediate, after CustomerInformation dialog</b>                                            | Highest available | ""                               | 1                          | 1                                |                                                                                                   |

**Table 5** • ALLUSERS Value on Windows Vista with UAC Enabled (cont.)

| Immediate             | Administrator   | 1                                | 1                          | 1                                |                                                                                                                                             |
| Immediate             | Limited         | 1                                | 1                          | 1                                | The InstallScript variable cannot be changed. The installation fails during UI sequence, and per-machine InstallScript custom actions fail. |

**Table 6** • ALLUSERS Value on Systems Earlier than Windows Vista and on Windows Vista with UAC Disabled (cont.)

| Type of Custom Action                                                                         | User Privileges | ALLUSERS Value in Property Table | Windows Installer Property | Resulting InstallScript Variable | Notes                                                                                                |
|-----------------------------------------------------------------------------------------------|-----------------|----------------------------------|----------------------------|----------------------------------|------------------------------------------------------------------------------------------------------|
| <b>Immediate, before CustomerInformation dialog (or end user selects to install per user)</b> | Administrator   | ""                               | ""                         | 0                                | The InstallScript variable cannot be changed. Per-machine InstallScript actions are not possible.    |
| <b>Immediate, after CustomerInformation dialog</b>                                            | Administrator   | ""                               | 1                          | 1                                |                                                                                                      |
| <b>Deferred</b>                                                                               | Administrator   | Any                              | Cannot be determined       | 1                                | InstallScript method for determining ALLUSERS is used.                                               |
| <b>Deferred</b>                                                                               | Limited         | Any                              | Cannot be determined       | 0                                | The InstallScript variable cannot be changed. InstallScript method for determining ALLUSERS is used. |
| <b>Any on Windows 9x</b>                                                                      | Not applicable  | Any                              | Any                        | 1                                | The InstallScript variable cannot be changed. InstallScript method for determining ALLUSERS is used. |

If the resulting InstallScript variable is 0, InstallScript custom actions are used in a per-user context. If the resulting InstallScript variable is 1, InstallScript custom actions are used in a per-machine context.

## Event-Driven InstallScript Code in InstallScript MSI Installations

InstallScript MSI installations work similarly to InstallScript installations except that when the ALLUSERS InstallScript variable is changed, the installation attempts to update the Windows Installer property ALLUSERS as described for InstallScript custom actions.

During InstallScript MSI installations, the Windows Installer property ALLUSERS is not queried to determine the appropriate value of the ALLUSERS InstallScript variable; the InstallScript engine always attempts to determine the value, as described for InstallScript installations.

## How an InstallScript Installation Works by Default Depending on ALLUSERS

**Project** ▪ This information applies to InstallScript projects.

The following table provides information on how an installation is installed based on the ALLUSERS system variable.

**Table 7** ▪ ALLUSERS

|                                                       | Admin & Power User                                           | User and Guest                                         |
|-------------------------------------------------------|--------------------------------------------------------------|--------------------------------------------------------|
| <b>Default setting of ALLUSERS</b>                    | True                                                         | False                                                  |
| <b>Automatic setting will check ALLUSERS property</b> | Per machine                                                  | Per user                                               |
| <b>HKEY_USER_SELECTABLE_AUTO</b>                      | HKEY_LOCAL_MACHINE                                           | HKEY_CURRENT_USER                                      |
| <b>Registry Set Data</b>                              | HKEY_LOCAL_MACHINE                                           | HKEY_CURRENT_USER                                      |
| <b>DISK1TARGET</b>                                    | Program Files\InstallShield<br>Installation Information\GUID | My Docs\InstallShield Installation<br>Information\GUID |
| <b>Uninstall Registry Key</b>                         | HKEY_LOCAL_MACHINE\...\Uninstall\GUID                        | HKEY_CURRENT_USER\...\Uninstall\GUID                   |
| <b>TARGETDIR</b>                                      | Program Files\Company<br>Name\Product Name                   | My Docs\Company Name\Product<br>Name                   |
| <b>Engine Installation</b>                            | Program Files\Common Files                                   | My Docs\...                                            |
| <b>Register COM Information (.dll, .ocx, .exe)</b>    | Supported                                                    | Not supported                                          |

**Note** ▪ My Docs refers to a destination location to which the user has rights. This value depends on the operating system.

## ADMINUSER

**Project** ▪ This information applies to the following project types:

- Basic MSI projects with InstallScript custom actions
- InstallScript MSI projects with InstallScript custom actions

*This information does not apply to InstallScript projects or to event-driven InstallScript code in InstallScript MSI projects.*

The ADMINUSER system variable is set to the value of the Windows Installer property AdminUser.

## BATCH\_INSTALL

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI—if the InstallScript user interface (UI) style is the traditional style (which uses the InstallScript engine as an external UI handler)

*This information does not apply to InstallScript MSI projects in which the InstallScript UI style is the new style (which uses the InstallScript engine as an embedded UI handler). To learn more, see [Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations](#).*

The BATCH\_INSTALL system variable is set to a non-zero value to indicate that one or more operations need to be performed after the target system restarts. BATCH\_INSTALL can be set to a non-zero value for any of the following reasons:

- The installation determines that a file cannot be installed because the file already exists on the target system and it is locked.
- BATCH\_INSTALL is set to non-zero manually through script. Note that this can occur in some objects if the object determines that an embedded installation needs a reboot to complete.
- LAAW\_OPTION\_SET\_BATCH\_INSTALL is used when calling **LaunchApplication**, and the function determines that the launched installation needs a reboot to complete.
- The installation attempted to update a Windows service (through **ServiceAddService** and the related functions), but it could not stop the existing service.
- The DIFx integration indicated that a reboot is needed, due to the installation of a DIFx driver.

If BATCH\_INSTALL is set to FALSE, no locked files were found and the installation process can end normally.

For more information, see [Understanding When an Installation or Uninstallation Restarts the Target System](#).

## CMDLINE

The CMDLINE variable varies, depending on the project type.

### CMDLINE in InstallScript Projects

In InstallScript projects, Setup.exe accepts all user-defined command-line arguments and assigns them to the system string variable CMDLINE at run time.

**Note** ▪ CMDLINE stores only user-defined command-line arguments. InstallShield command-line arguments (predefined arguments) are not copied to CMDLINE.

## CMDLINE in InstallScript Installations That Are Included in Advanced UI and Suite/Advanced UI Projects as InstallScript Packages

Data can be passed to an InstallScript package through the package's Command Line and Silent Command Line settings in the Advanced UI or Suite/Advanced UI project that contains the InstallScript package. The data can then be parsed from the CMDLINE variable in the Advanced UI or Suite/Advanced UI script events. For more information, see [OnSuiteShowUI](#).

## CMDLINE in InstallScript MSI Projects

In InstallScript MSI projects, any command-line data that are passed to Setup.exe with the /z switch are stored in the system string variable CMDLINE. For example, if the user runs the following command line, CMDLINE is set to the string **My custom data**.

```
Setup.exe /z"My custom data"
```

## CMDLINE in Basic MSI Projects

In Basic MSI projects, you can pass public properties through Setup.exe to Msiexec.exe using the /v command-line argument.

# COMMONFILES

The COMMONFILES system variable contains the fully qualified name of the folder that is defined by Windows and that stores files shared by applications that are installed on the system. In English Windows, that folder is named Common Files, and it is located in the Program Files folder. (In other language versions of Windows, the common files folder name is localized appropriately by default.) The common files folder is the recommended default location for files and folders that are shared by applications.

On 64-bit Windows systems, this folder stores common files for 32-bit applications; common files for 64-bit applications should be installed to the COMMONFILES64 folder.

---

**Project** ▪ During setup initialization in InstallScript installations, the value of the COMMONFILES variable is obtained by calling the Windows API function **SHGetSpecialFolderPath** with the **CSIDL\_COMMON\_FILES** parameter.

In Basic MSI and InstallScript MSI installations, the value of the COMMONFILES variable is initialized based on the Windows Installer property **CommonFilesFolder**. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding COMMONFILES variable is empty in deferred, commit, and rollback custom actions. To learn more, see [Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions](#).

# COMMONFILES64

The COMMONFILES64 system variable contains the fully qualified name of the folder that is defined by Windows and that stores files shared by 64-bit applications. In English Windows, that folder is named Common Files, and it is located in the PROGRAMFILES64 folder. (In other language versions of Windows, the common files folder name is localized appropriately by default.) The common files folder is the recommended default location for files and folders that are shared by applications.

**Project** ▪ During setup initialization in InstallScript installations, the value of the `COMMONFILES64` variable is obtained by calling the Windows API function `SHGetSpecialFolderPath` with the `CSIDL_COMMON_FILES` parameter from a 64-bit executable file.

In Basic MSI and InstallScript MSI installations, the value of the `COMMONFILES64` variable is initialized based on the Windows Installer property `CommonFiles64Folder`. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding `COMMONFILES64` variable is empty in deferred, commit, and rollback custom actions. To learn more, see [Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions](#).

## DISK1SETUPEXENAME

`DISK1SETUPEXENAME` is a read-only system variable that contains the file name and file name extension—but not the path—of the setup launcher, the installation's executable file. This now used internally and always returns `Setup.exe`.

Refer `SETUPEXENAME` to get the actual executing setup exe name.

**Project** ▪ `DISK1SETUPEXENAME` is intended for use in InstallScript projects only. Using this variable with other project types may result in different behavior or scenarios where the variable is not set as expected.

## SETUPEXENAME

`SETUPEXENAME` is a read-only system variable that contains the executing setup exe name.

**Project** ▪ `SETUPEXENAME` is intended for use in InstallScript projects only. Using this variable with other project types may result in different behavior or scenarios where the variable is not set as expected.

## DISK1TARGET

This system variable contains the path to the folder in which copies of certain of the installation's files (such as the compiled script file) are placed to enable maintenance installations and uninstallation.

## ENABLED\_ISERVICES

**Project** ▪ This information applies to InstallScript projects.

This system variable contains a set of bit flags indicating which InstallShield services are currently enabled. For example, if the expression `ENABLED_ISERVICES & SERVICE_FLAG_ISFONTREG` is equal to a non-zero value, global font registration is currently enabled.

## ENGINECOMMONDIR

**Project** ▪ This information applies to InstallScript projects.

The ENGINECOMMONDIR system variable stores the fully qualified path to the folder that contains the run-time files that are used by all 6.x, 7.x, and 9.x InstallScript (not InstallScript MSI) setups running on the system.

The value of this system variable is shared among object scripts and between object scripts and the main setup script. This system variable is read-only; if you attempt to assign a value to it, a compiler error results.

## ENGINEDIR

**Project** ▪ This information applies to InstallScript projects.

The ENGEDIR system variable stores the fully qualified path to the folder that contains the run-time files specific to the version of the engine being used by the setup, i.e., 7.00, 7.01, or 9.00, but not by InstallShield Professional 6.x setups.

The value of this system variable is shared among object scripts and between object scripts and the main setup script. This system variable is read-only; if you attempt to assign a value to it, a compiler error results.

## ERRORFILENAME

This system variable stores the name of the file that was involved in an error. For example, if an error occurs while copying a specific file with a built-in function, InstallShield sets ERRORFILENAME to the name of the file that caused the error. Not all file-operation functions use ERRORFILENAME.

## FOLDER\_APPDATA

The FOLDER\_APPDATA system variable stores the fully qualified path to the folder that is defined by the operating system and that serves as a common repository for application-specific data.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

**Project** ▪ During setup initialization in InstallScript installations, the value of the FOLDER\_APPDATA variable is obtained by calling the Windows API function **SHGetSpecialFolderPath** with the CSIDL\_APPDATA value for LPITEMIDLIST.

In Basic MSI and InstallScript MSI installations, the value of the FOLDER\_APPDATA variable is initialized based on the Windows Installer property AppDataFolder or LocalAppDataFolder. Note that deferred, commit, and rollback custom actions do not have access to these properties. Therefore, the corresponding FOLDER\_APPDATA variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## FOLDER\_APPLICATIONS

The FOLDER\_APPLICATIONS system variable stores the fully qualified path to the root folder for application folders. The value of this system variable is equal to the value of the system variable **PROGRAMFILES** when the value of the system variable **ALLUSERS** is non-zero; when **ALLUSERS** is FALSE, the value of this system variable is equal to the value of the system variable **FOLDER\_APPDATA**.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

## FOLDER\_APPLICATIONS64

The FOLDER\_APPLICATIONS64 system variable stores the fully qualified path to the root folder for application folders on a 64-bit system. The value of this system variable is equal to the value of the system variable **PROGRAMFILES64** when the value of the system variable **ALLUSERS** is non-zero; when **ALLUSERS** is FALSE, the value of this system variable is equal to the value of the system variable **FOLDER\_APPDATA**.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

## FOLDER\_COMMON\_APPDATA

The FOLDER\_COMMON\_APPDATA system variable stores the fully qualified path to the folder that is defined by the operating system and that serves as a common repository for application-specific data.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

---

**Project** - During setup initialization in InstallScript installations, the value of the FOLDER\_COMMON\_APPDATA variable is obtained by calling the Windows API function **SHGetSpecialFolderPath** with the **CSIDL\_COMMON\_APPDATA** value for **LPITEMIDLIST**.

In Basic MSI and InstallScript MSI installations, the value of the FOLDER\_COMMON\_APPDATA variable is initialized based on the Windows Installer property **CommonAppDataFolder**. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding FOLDER\_COMMON\_APPDATA variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## FOLDER\_DESKTOP

The FOLDER\_DESKTOP system variable stores the fully qualified path to the Desktop folder, which holds the program folders and items that are displayed on the end user's desktop.

To ensure that groups and folders are created at the proper location, the location to which FOLDER\_DESKTOP points changes when the default group or folder type is changed from Common to Personal or from Personal to Common when the system variable **ALLUSERS** is changed.

## FOLDER\_DOTNET\_10

The FOLDER\_DOTNET\_10 system variable stores the fully qualified path of the folder where the Microsoft .NET Framework 1.0 redistributable files are located:

```
<WINDIR>\Microsoft.NET\Framework\v1.0.3705\
```

This system variable is read-only. If you attempt to assign a value to it, a compiler error results.

## FOLDER\_DOTNET\_11

The FOLDER\_DOTNET\_11 system variable stores the fully qualified path of the folder where the Microsoft .NET Framework 1.1 redistributable files are located:

```
<WINDIR>\Microsoft.NET\Framework\v1.1.4322\
```

This system variable is read-only. If you attempt to assign a value to it, a compiler error results.

## FOLDER\_DOTNET\_20

The FOLDER\_DOTNET\_20 system variable stores the fully qualified path of the folder where the Microsoft .NET Framework 2.0 redistributable files are located:

```
<WINDIR>\Microsoft.NET\Framework\v2.0.50727\
```

This system variable is read-only. If you attempt to assign a value to it, a compiler error results.

## FOLDER\_DOTNET\_30

The FOLDER\_DOTNET\_30 system variable stores the fully qualified path of the folder where the Microsoft .NET Framework 3.0 redistributable files are located:

```
<WINDIR>\Microsoft.NET\Framework\v3.0
```

This system variable is read-only. If you attempt to assign a value to it, a compiler error results.

## FOLDER\_DOTNET\_35

The FOLDER\_DOTNET\_35 system variable stores the fully qualified path of the folder where the Microsoft .NET Framework 3.5 redistributable files are located:

```
<WINDIR>\Microsoft.NET\Framework\v3.5
```

This system variable is read-only. If you attempt to assign a value to it, a compiler error results.

## FOLDER\_DOTNET\_40

The FOLDER\_DOTNET\_40 system variable stores the fully qualified path of the folder where the Microsoft .NET Framework 4.0 redistributable files are located:

```
<WINDIR>\Microsoft.NET\Framework\v4.0.30319
```

This system variable is read-only. If you attempt to assign a value to it, a compiler error results.

## FOLDER\_FONTS

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript Object*

The FOLDER\_FONTS system variable stores the fully qualified path of the Windows font folder.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

## FOLDER\_LOCAL\_APPDATA

The FOLDER\_LOCAL\_APPDATA system variable stores the fully qualified path to the folder that is defined by the operating system and that serves as a common repository for application-specific data. Common values are C:\Users\<User>\Application Data on Windows Vista and later and C:\Documents and Settings\<User>\Application Data on earlier systems.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

**Project** • During setup initialization in InstallScript installations, the value of the FOLDER\_LOCAL\_APPDATA variable is obtained by calling the Windows API function **SHGetSpecialFolderPath** with the CSIDL\_LOCAL\_APPDATA value for LPITEMIDLIST.

In Basic MSI and InstallScript MSI installations, the value of the FOLDER\_LOCAL\_APPDATA variable is initialized based on the Windows Installer property LocalAppDataFolder. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding FOLDER\_LOCAL\_APPDATA variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## FOLDER\_PERSONAL

**Project** • This information applies to InstallScript projects.

The FOLDER\_PERSONAL system variable stores the fully qualified path to the folder that is defined by the operating system and that serves as a common repository for application-specific data. Common values are C:\Users\<User>\Application Data on Windows Vista and later and C:\Documents and Settings\<User>\Application Data on earlier systems.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

**Project** ▪ During setup initialization in InstallScript installations, the value of the `FOLDER_PERSONAL` variable is obtained by calling the Windows API function `SHGetSpecialFolderPath` with the `CSIDL_PERSONAL` value for `LPITEMIDLIST`.

In Basic MSI and InstallScript MSI installations, the value of the `FOLDER_PERSONAL` variable is initialized based on the Windows Installer property `PersonalFolder`. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding `FOLDER_PERSONAL` variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## FOLDER\_PROGRAMS

The `FOLDER_PROGRAMS` system variable stores the fully qualified path to the Start Menu\Programs folder, which is displayed when you select Programs from the Start Menu.

To ensure that groups and folders are created at the proper location, the location to which `FOLDER_PROGRAMS` points changes when the default group or folder type is changed from Common to Personal or from Personal to Common when the system variable `ALLUSERS` is changed.

## FOLDER\_STARTMENU

The `FOLDER_STARTMENU` system variable stores the fully qualified path to the Start Menu folder, which is displayed when you click the Windows Start button.

To ensure that groups and folders are created at the proper location, the location to which `FOLDER_STARTMENU` points changes when the default group or folder type is changed from Common to Personal or from Personal to Common when the system variable `ALLUSERS` is changed.

## FOLDER\_STARTUP

The `FOLDER_STARTUP` system variable stores the fully qualified path to the Startup folder, which contains the program folders and items that are launched when Windows starts.

To ensure that groups and folders are created at the proper location, the location to which `FOLDER_STARTUP` points changes when the default group or folder type is changed from Common to Personal or from Personal to Common when the system variable `ALLUSERS` is changed.

## FOLDER\_TEMP

**Project** ▪ This information applies to InstallScript projects.

The `FOLDER_TEMP` system variable stores the fully qualified path of the folder designated for temporary files. This folder is used by Windows and most applications on the system and is not created or deleted by the installation. (The folder whose path is stored in the system variable `SUPPORTDIR` is created by the installation to store installation-specific files and is deleted after the installation completes.)

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

**Project** ▪ During setup initialization in InstallScript installations, the value of the `FOLDER_TEMP` variable is obtained by calling the Windows API function `GetTempPath`.

In Basic MSI and InstallScript MSI installations, the value of the `FOLDER_TEMP` variable is initialized based on the Windows Installer property `TempFolder`. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding `FOLDER_TEMP` variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## HKEYCURRENTROOTKEY

The value of this system variable is the root key that is used by the general registry-related functions. The system variable's possible values are the following:

- `HKEY_CLASSES_ROOT`
- `HKEY_CURRENT_USER`
- `HKEY_LOCAL_MACHINE`
- `HKEY_USERS`
- `HKEY_CURRENT_CONFIG`
- `HKEY_DYN_DATA`

You can set the default root key by setting `HKEYCURRENTROOTKEY` equal to one of the preceding predefined constants, the predefined constant `HKEY_USER_SELECTABLE`, or the system variable `HKEY_USER_SELECTABLE_AUTO`.

Unlike `RegDBGetDefaultRoot`, the value of `HKEYCURRENTROOTKEY` is never `HKEY_USER_SELECTABLE`. If you most recently set the default root key by using `HKEY_USER_SELECTABLE`, the value of `HKEYCURRENTROOTKEY` is `HKEY_LOCAL_MACHINE` if the `ALLUSERS` system variable is non-zero or `HKEY_CURRENT_USER` if `ALLUSERS` is `FALSE`.

## HKEY\_USER\_SELECTABLE\_AUTO

The value of this system variable is `HKEY_LOCAL_MACHINE` if the `ALLUSERS` system variable is non-zero or `HKEY_CURRENT_USER` if `ALLUSERS` is `FALSE`.

## IFX\_COMPANY\_NAME

**Project** ▪ This information applies to InstallScript projects.

This system variable is automatically initialized to the value of the string entry COMPANY\_NAME, if that entry exists; if that entry does not exist, IFX\_COMPANY\_NAME is initialized to the company name that you specified in the Project Settings property sheet's Application page.

## IFX\_DISK1INSTALLED

**Project** ▪ This information applies to InstallScript projects.

This system variable is set equal to zero at the beginning of a setup and is reset to a non-zero value if the setup installs or reinstalls the feature with the files needed for maintenance setups and uninstallation. (Note that this feature is automatically placed in your .cab files by the media builder and is not displayed in the IDE.)

## IFX\_INITIALIZED

**Project** ▪ This information applies to InstallScript projects.

This system variable is set equal to a non-zero value if the setup is event based and is set equal to FALSE if the setup is procedural (that is, has a program...endprogram block).

## IFX\_INSTALLED\_DISPLAY\_VERSION

**Project** ▪ This information applies to InstallScript projects.

The IFX\_INSTALLED\_DISPLAY\_VERSION system variable replaces the placeholder %VI in Sd dialog static text fields and string passed to the **SdSubstituteProductInfo** function. This system variable is automatically initialized to the value of the system variable IFX\_INSTALLED\_VERSION; if you assign a new value to IFX\_INSTALLED\_VERSION the value of IFX\_INSTALLED\_DISPLAY\_VERSION does not automatically change.

## IFX\_INSTALLED\_VERSION

**Project** ▪ This information applies to InstallScript projects.

This system variable is automatically initialized to the string equivalent of the data in the Version value of the application uninstallation registry key if that data is a packed DWORD; if the key or value does not exist or the data is not a packed DWORD, IFX\_INSTALLED\_VERSION is initialized to a null string ("").

## IFX\_KEYPATH\_PRODUCT\_INFO

This system variable specifies the registry location of the application information key that is created by [CreateInstallationInfo](#) and whose values are read by [RegDBGetAppInfo](#) and modified by [RegDBSetAppInfo](#). This system variable is initialized to a value of:

Software\<IFX\_COMPANY\_NAME>\<IFX\_PRODUCT\_NAME>\<IFX\_PRODUCT\_VERSION>\.

## IFX\_MULTI\_INSTANCE\_SUFFIX

**Project** ▪ This information applies to InstallScript projects.

The IFX\_MULTI\_INSTANCE\_SUFFIX system variable is set in the default code for the [OnFirstUIBefore](#) event handler function. IFX\_MULTI\_INSTANCE\_SUFFIX is used in that handler function to construct a unique target folder name for a multi-instance installation. It is also used in the [OnCustomizeUninstInfo](#) handler function to construct a unique uninstallation display name for a multi-instance installation.

## IFX\_PRODUCT\_COMMENTS

**Project** ▪ This information applies to InstallScript projects.

If this system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's Comments value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the value that you specify in ARP Comments setting in the General Information view.

## IFX\_PRODUCT\_DISPLAY\_NAME

This system variable replaces the placeholder %P in Sd dialog static text fields and string passed to the **SdSubstituteProductInfo** function. This system variable is automatically initialized to the value of the system variable IFX\_PRODUCT\_NAME; if you assign a new value to IFX\_PRODUCT\_NAME the value of IFX\_PRODUCT\_DISPLAY\_NAME does not automatically change.

**Note** ▪ The system variable IFX\_SETUP\_TITLE specifies the text in the title bar of all built-in dialogs.

## IFX\_PRODUCT\_DISPLAY\_VERSION

**Project** ▪ This information applies to InstallScript projects.

This system variable replaces the placeholder %VS in Sd dialog static text fields and string passed to the **SdSubstituteProductInfo** function. This system variable is automatically initialized to the value of the system variable IFX\_PRODUCT\_VERSION; if you assign a new value to IFX\_PRODUCT\_VERSION the value of IFX\_PRODUCT\_DISPLAY\_VERSION does not automatically change.

## IFX\_PRODUCT\_ICON

**Project** ▪ This information applies to InstallScript projects.

If this system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's DisplayIcon value. This registry value specifies the icon that is displayed for the application in Add or Remove Programs in the Control Panel.

This system variable is initialized to the value that you specify for the Display Icon setting in the Add or Remove Programs area of the General Information view.

## IFX\_PRODUCT\_KEY

**Project** ▪ This information applies to InstallScript projects.

This system variable is automatically initialized to the value of the string entry PRODUCT\_KEY, if that entry exists; if that entry does not exist, IFX\_PRODUCT\_KEY is initialized to the executable file name that you specified in the Project Settings property sheet's Application page.

## IFX\_PRODUCT\_NAME

**Project** ▪ This information applies to InstallScript projects.

This system variable is automatically initialized to the value of the string entry PRODUCT\_NAME, if that entry exists; if that entry does not exist, IFX\_PRODUCT\_NAME is initialized to the product name that you specified in the Project Settings property sheet's Application page.

## IFX\_PRODUCT\_README

**Project** ▪ This information applies to InstallScript projects.

If this system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's Readme value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the value that you specify in the Read Me setting in the General Information view.

## IFX\_PRODUCT\_REGISTEREDCOMPANY

If the `IFX_PRODUCT_REGISTEREDCOMPANY` system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's `RegCompany` value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the data in the registry value `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows key\CurrentVersion\RegisteredOrganization`, where `Windows key` is `Windows NT` if the target operating system is Windows XP or later, or `Windows` for other Windows operating systems. This system variable's value is modified by end-user input in the Company Name edit box of the [SdRegisterUser](#), [SdRegisterUserEx](#), [SdCustomerInformation](#), and [SdCustomerInformationEx](#) dialogs.

---

**Project** • In an `InstallScript` MSI installation, if the value of `IFX_PRODUCT_REGISTEREDCOMPANY` is set, the Windows Installer property **COMPANYNAME** is automatically updated.

## IFX\_PRODUCT\_REGISTEREDOWNER

If the `IFX_PRODUCT_REGISTEREDOWNER` system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's `RegOwner` value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the data in the registry value `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows key\CurrentVersion\RegisteredOwner`, where `Windows key` is `Windows NT` if the target operating system is Windows XP or later, or `Windows` for other Windows operating systems. This system variable's value is modified by end-user input in the User Name edit box of the [SdRegisterUser](#), [SdRegisterUserEx](#), [SdCustomerInformation](#), and [SdCustomerInformationEx](#) dialogs.

---

**Project** • In an `InstallScript` MSI installation, if the value of `IFX_PRODUCT_REGISTEREDOWNER` is set, the Windows Installer property **USERNAME** is automatically updated.

## IFX\_PRODUCT\_REGISTEREDSERIALNUM

If the `IFX_PRODUCT_REGISTEREDSERIALNUM` system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's `ProductId` value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable's value is modified by end-user input in the Serial Number edit box of the [SdCustomerInformation](#), and [SdCustomerInformationEx](#) dialogs.

## IFX\_PRODUCT\_SUPPORT\_CONTACT

---

**Project** • This information applies to `InstallScript` projects.

If this system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's Contact value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the value that you specify in the Support Contact setting in the General Information view.

## IFX\_PRODUCT\_SUPPORT\_PHONE

---

**Project** ▪ This information applies to InstallScript projects.

If this system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's HelpTelephone value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the value that you specify in the Support Phone Number setting in the General Information view.

## IFX\_PRODUCT\_SUPPORT\_URL

---

**Project** ▪ This information applies to InstallScript projects.

If this system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's HelpLink value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the value that you specify in the Support URL setting in the General Information view.

## IFX\_PRODUCT\_UPDATE\_URL

---

**Project** ▪ This information applies to InstallScript projects.

If this system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the [application uninstallation registry key's](#) URLUpdateInfo value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the value that you specify in the Product Update URL setting in the General information view.

## IFX\_PRODUCT\_URL

---

**Project** ▪ This information applies to InstallScript projects.

If this system variable's value is not a null string (""), its value is used by the [MaintenanceStart](#) function to specify the data in the application uninstallation registry key's URLInfoAbout value. This registry value provides information about the application to Add or Remove Programs in the Control Panel.

This system variable is initialized to the value that you specify in the Publisher/Product URL setting in the General Information view.

## IFX\_PRODUCT\_VERSION

---

**Project** • This information applies to InstallScript projects.

This system variable is automatically initialized to the value of the string entry PRODUCT\_VERSION, if that entry exists; if that entry does not exist, IFX\_PRODUCT\_VERSION is initialized to the product version that you specified in the Project Settings property sheet's Application page.

## IFX\_SETUP\_TITLE

This system variable specifies the text in the title bar of all built-in dialogs (except dialogs generated directly by Windows API function calls) and all message boxes generated by the MessageBox function. This system variable is automatically initialized to the value of the string entry TITLE\_CAPTIONBAR, if that entry exists; if that entry does not exist, IFX\_SETUP\_TITLE is initialized with the following internal code:

```
Sprintf( IFX_SETUP_TITLE, SdLoadString( IDS_IFX_FORMAT_SETUP_TITLE ), IFX_PRODUCT_DISPLAY_NAME );
```

Changing the value of IFX\_SETUP\_TITLE automatically resets the title of all dialogs displayed by the setup.

## IFX\_SUPPORTED\_VERSIONS

---

**Project** • This information applies to InstallScript projects.

This system variable is automatically initialized to a pipe(|)-delimited list of the versions of your product to which the update can be applied, which you specified in the media property sheet's Update page or the Media Wizard's Update panel.

## INFOFILENAME

When you use [BatchFileSave](#) to save a batch file or [ConfigFileSave](#) to save a Config.sys file, you can specify that InstallShield create a backup of the file as it existed before you updated it. InstallShield assigns the name of that backup file to the system variable INFOFILENAME. If you want to alert the user to the existence of the backup file, use the function MessageBox to display the value of INFOFILENAME.

## INSTALLDIR

**Project** ▪ This information applies to the following project types:

- Basic MSI
- InstallScript MSI

In an InstallScript project, use **TARGETDIR**.

During setup initialization, the installation assigns to the system variable **INSTALLDIR** the fully qualified path to a target folder on the hard drive. The **INSTALLDIR** path is resolved based on the destination that is specified in the **INSTALLDIR** setting in the General Information view. By default, the **INSTALLDIR** path is resolved based on the [ProgramFilesFolder]ISYourCompanyDir\ISYourProductDir entries in the Directory table of your .msi package.

## INSTANCE\_GUID

**Project** ▪ This information applies to InstallScript projects.

This system variable contains a globally unique identifier (GUID) for the installation, which is used as the name of the application uninstallation registry key. This variable's value is set at run time to equal **PRODUCT\_GUID** except in a multi-instance installation.

The value of this system variable is shared among object scripts and between object scripts and the main installation script. You cannot assign a new value to this system variable.

## ISDIFXAPPID

This predefined global system variable determines the application to associate when installing or uninstalling device drivers. **ISDIFXAPPID** is set to **PRODUCT\_GUID** by default during initialization and can be changed as desired to specify an alternate application ID.

**Note** ▪ See the *DIFxAPI* documentation for the *INSTALLERINFO* structure for more information regarding specifying application association.

## ISMSI\_HANDLE

This system variable is set to the handle of the currently running .msi database, and can be used in event-handler functions as an argument to Windows Installer API functions that require a handle to the currently running database.

For example, to retrieve the value of the **USERNAME** property in the **OnBegin** event handler, you can use code similar to the following:

```
function OnBegin( )
    STRING svUsername[256];
    NUMBER nBuffer;
```

```
begin
  nBuffer = 256;
  MsiGetProperty(ISMSI_HANDLE, "USERNAME", svUsername, nBuffer);
  MessageBox("USERNAME = " + svUsername, INFORMATION);
end;
```

---

**Project** • *ISMSI\_HANDLE is not supported in Basic MSI projects, and is not supported in InstallScript custom actions.*

## IS\_NULLSTR\_PTR

You can use the IS\_NULLSTR\_PTR variable to pass a null pointer to an external DLL function or Windows API through a parameter that has been prototyped as an InstallScript string. This functionality works for byval string, byref string, wstring, and binary data types.

This functionality does not apply to byref number parameters. If you want to specify a NULL pointer for byref number parameters, you must prototype the parameter as a pointer data type and pass the address of the number variable or NULL, as needed.

IS\_NULLSTR\_PTR is a global string variable instance with the value of <IS\_NULLSTR\_PTR>. A statement that assigns a new value to this variable compiles; however, the assignment does not have any effect. The variable's value remains <IS\_NULLSTR\_PTR>.

If you pass this variable to a non-DLL function, the function receives the string <IS\_NULLSTR\_PTR>.

If you pass a string that has the value <IS\_NULLSTR\_PTR> to an external DLL function, the result is the same as if you used IS\_NULLSTR\_PTR.

### Using the IS\_NULLSTR\_PTR Variable to Pass a Null Pointer to a Windows API

The Windows function **WritePrivateProfileString** lets you flush the INI file buffer on Windows 9x by specifying NULL for the first three parameters. However, since this function is prototyped as follows, there does not appear to be any way to accomplish this:

```
prototype number   KERNEL32.WritePrivateProfileString (byval string, byval string, byval string, byval
string);
```

Using the pointer data type allows NULL to be specified, but it causes problems when trying to specify a valid string.

If you want the InstallScript engine to pass a null pointer to the function, you can use the following code:

```
KERNEL32.WritePrivateProfileString (IS_NULLSTR_PTR, IS_NULLSTR_PTR, IS_NULLSTR_PTR, szFile);
```

### Using the IS\_NULLSTR\_PTR Variable to Pass a Null Pointer to an External DLL Function

You can use IS\_NULLSTR\_PTR with any external DLL function that expects a string. In this case, the DLL function receives a NULL pointer.

## ISRES

During setup initialization, the installation decompresses `_isres.dll` from your setup and copies it to a temporary folder on the target system, giving it a unique name so that it does not interfere with other InstallShield installations. The fully qualified name of this file, which contains setup resources, is assigned to the system variable ISRES.

## ISUSER

During setup initialization, the installation decompresses `_isuser.dll`, if present, from your setup and copies it to the temporary folder SUPPORTDIR on the target system, giving the file a unique name so that it does not interfere with other InstallShield installations. The fully qualified name of this file, which contains user-defined setup resources, is assigned to the system variable ISUSER.

## ISVERSION

When the setup script starts running, the installation gets the version of Setup.exe that is running and assigns it to the system variable ISVERSION. The version number also appears in the Setup program's About box.

## LAAW\_PARAMETERS

If you call **LaunchApplication** without `LAAW_OPTION_USE_SHELLEXECUTE` or you call **LaunchAppAndWait** or **LaunchApp**, these functions internally call the Windows API function **CreateProcess**. The `LAAW_PARAMETERS` structured variable specifies certain arguments for **CreateProcess**, and whether to display a text window while the launched application is running. For information on **CreateProcess**, consult the Windows API documentation.

The `LAAW_PARAMETERS` system variable is initialized automatically during setup initialization by a call to [LaunchAppAndWaitInitStartupInfo](#).

**Table 8 • LAAW\_PARAMETERS**

| Member                    | Description                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bCallbackEndedWait</b> | Indicates that <b>WaitForApplication</b> ended the wait because the callback function returned <code>LAAW_CALLBACK_RETURN_END_WAIT</code> .                                                                                                                                                                                                 |
| <b>bInheritHandles</b>    | Sets the corresponding argument to <b>CreateProcess</b> .                                                                                                                                                                                                                                                                                   |
| <b>dwCreationFlags</b>    | Sets the corresponding argument to <b>CreateProcess</b> .                                                                                                                                                                                                                                                                                   |
| <b>lpCurrentDirectory</b> | Sets the corresponding argument to <b>CreateProcess</b> . This member is set to the <code>szDirectory</code> parameter of <b>LaunchApplication</b> or <b>LaunchAndAppAndWait</b> .<br><br>Note that setting the value of <code>lpCurrentDirectory</code> manually has no effect on <b>LaunchApplication</b> or <b>LaunchAndAppAndWait</b> . |
| <b>lpEnvironment</b>      | Sets the corresponding argument to <b>CreateProcess</b> .                                                                                                                                                                                                                                                                                   |

Table 8 • LAAW\_PARAMETERS (cont.)

| Member                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>lpProcessAttributes</b>   | Sets the corresponding argument to <b>CreateProcess</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>lpThreadAttributes</b>    | Sets the corresponding argument to <b>CreateProcess</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>nCallbackInterval</b>     | This member defines the callback interval in milliseconds. It is set to 1000 (1 second) by default when you call the <b>LaunchApplicationInit</b> or <b>LaunchAppAndWaitInitStartupInfo</b> functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>nLaunchResult</b>         | If the application cannot be launched, the <b>nLaunchResult</b> member contains the result of calling <b>GetLastError</b> after the <b>CreateProcess</b> call. If <b>LaunchApp</b> , <b>LaunchAppAndWait</b> , or <b>LaunchApplication</b> is successful and the <b>LAAW_OPTION_WAIT</b> option was specified, the <b>nLaunchResult</b> member contains the return code of the launched application.                                                                                                                                                                                                                                                    |
| <b>nTimeout</b>              | Indicates the timeout value used internally by <b>LaunchApplication</b> or <b>LaunchAndAppAndWait</b> when <b>WaitForApplication</b> is called. The default value is INFINITE. You can customize this value to set a wait timeout for <b>LaunchApplication</b> or <b>LaunchAndAppAndWait</b> .                                                                                                                                                                                                                                                                                                                                                          |
| <b>nTimeoutCheckInterval</b> | Indicates the interval for how often the installation checks whether the timeout interval has elapsed while waiting for an application through <b>WaitForApplication</b> (or through <b>LaunchApplication</b> or <b>LaunchAndAppAndWait</b> , which may call <b>WaitForApplication</b> internally). This value is not used if <b>nTimeout</b> is set to INFINITE and <b>LAAW_USE_CALLBACK</b> is not specified. If <b>LAAW_USE_CALLBACK</b> is specified, the timeout/callback check interval is the lower of the two values for <b>LAAW_PARAMETERS.nTimeoutCheckInterval</b> and <b>LAAW_PARAMETERS.nCallbackInterval</b> . The default value is 1000. |
| <b>nWaitForInputIdleMax</b>  | Indicates the maximum amount of time (in milliseconds) to wait for the application to complete its initialization through the Windows API <b>WaitForInputIdle</b> . The default value for this structure member is 2000. You can set it to 0 to indicate that the installation should not wait for the application to initialize before beginning the wait for the application to complete.<br><br>Since <b>LaunchApplication</b> and <b>LaunchAndAppAndWait</b> wait for the application to initialize only if <b>LAAW_OPTION_WAIT</b> is specified, this value is only used if <b>LAAW_OPTION_WAIT</b> is specified.                                  |
| <b>nWaitResult</b>           | Indicates additional information about the last wait that occurred as a result of calling <b>WaitForApplication</b> . For more information, see <a href="#">WaitForApplication</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

Table 8 • LAAW\_PARAMETERS (cont.)

| Member                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szCommandLineResult</b> | Contains the resulting command line used as the <code>lpCommandLine</code> parameter in the internal call to <b>CreateProcess</b> . This member is populated when <b>LaunchApplication</b> or <b>LaunchAndAppAndWait</b> is called, so setting its value directly before or after this function is called has no effect. Also, this member is set to null ("" ) when you call the <b>LaunchApplicationInit</b> or <b>LaunchAppAndWaitInitStartupInfo</b> functions.                                                                                                  |
| <b>szStatusText</b>        |  <p><b>Project</b> ▪ The <code>szStatusText</code> member is not available for use in <i>InstallScript</i> actions that are called in <i>Suite/Advanced UI</i> installations.</p> <p>If this member is set to anything other than a null string ("" ), the installation displays its contents in a text window (by calling <code>SdShowMsg</code>) while the launched application is running. Note that <code>szStatusText</code> cannot contain more than 4 kilobytes of data.</p> |

## LAAW\_PROCESS\_INFORMATION

When you call **LaunchApplication**, **LaunchAndAppAndWait**, or **LaunchApp**, this structured variable returns identification information about the launched process. The `PROCESS_INFORMATION` system variable has the following members:

Table 9 • LAAW\_PROCESS\_INFORMATION

| Member             | Description                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hProcess</b>    | A handle to the newly created process. The handle is used to specify the process in all functions that perform operations on the process object.                      |
| <b>hThread</b>     | A handle to the primary thread of the newly created process. The handle is used to specify the thread in all functions that perform operations on the thread object.  |
| <b>dwProcessId</b> | A global process identifier that can be used to identify a process. The value is valid from the time the process is created until the time the process is terminated. |
| <b>dwThreadId</b>  | A global thread identifiers that can be used to identify a thread. The value is valid from the time the thread is created until the time the thread is terminated.    |

## LAAW\_SHELLEXECUTEINFO

The LAAW\_SHELLEXECUTEINFO script variable is an instance of a SHELLEXECUTEINFO structure used by the **LaunchApplication** function when the **ShellExecuteEx** function is called. You can customize the members of this structure to affect how using **LaunchApplication** with the LAAW\_OPTION\_USE\_SHELLEXECUTE parameter works.

### SHELLEXECUTEINFO Structure

```
typedef SHELLEXECUTEINFO
begin
    int      cbSize;
    int      fMask;
    HWND     hwnd;
    pointer  lpVerb;
    pointer  lpFile;
    pointer  lpParameters;
    pointer  lpDirectory;
    int      nShow;
    HWND     hInstApp;
    pointer  lpIDLlist;
    pointer  lpClass;
    HWND     hkeyClass;
    int      dwHotKey;
    HWND     hIconMonitor;
    HWND     hProcess;
end;
```

## LAAW\_SHELLEXECUTEVERB

The LAAW\_SHELLEXECUTEVERB script variable is a string that indicates the verb used by **LaunchApplication** when calling **ShellExecuteEx**. The default value is **open**. The lpVerb member of LAAW\_SHELLEXECUTEINFO points to this string by default.

**Tip** ▪ If you are using LAAW\_OPTION\_USE\_SHELLEXECUTE on systems running Windows Vista or later and you want to launch the application using the full administrator account (similar to right-clicking the executable file to be run and clicking Run as Administrator), set LAAW\_SHELLEXECUTEVERB to **runas** before using **LaunchApplication** in your script:

```
LAAW_SHELLEXECUTEVERB = "runas";
```

*This ensures that the application is always run with full administrator privileges regardless of whether the application to be launched has an application manifest with relevant settings. Note that this may trigger a User Account Control (UAC) prompt for consent or credentials.*

*On systems running operating systems earlier than Windows Vista, if `runas` is used, a Run As dialog box is displayed. The behavior is similar to right-clicking the executable file to be run and clicking Run As. This dialog box enables the end user to select the user account that should be used to run the application.*

## LAAW\_STARTUPINFO

When you call **LaunchApplication**, **LaunchAndAppAndWait**, or **LaunchApp**, the LAAW\_STARTUPINFO structured variable specifies main window properties if a new window is created for the launched process. This system variable is initialized automatically during installation initialization by a call to **LaunchAppAndWaitInitStartupInfo**.

The STARTUPINFO system variable has the following members:

**Table 10** • LAAW\_STARTUPINFO

| Member            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cb</b>         | Specifies the size, in bytes, of the structure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>lpReserved</b> | Reserved. Set this member to NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>lpDesktop</b>  | Pointer to a null-terminated string that specifies either the name of the desktop only or the name of both the desktop and window station for this process. A backslash in the string pointed to by <code>lpDesktop</code> indicates that the string includes both desktop and window station names. If <code>lpDesktop</code> is NULL, the new process inherits the desktop and window station of its parent process. If <code>lpDesktop</code> is an empty string, the process does not inherit the desktop and window station of its parent process; instead, the system determines if a new desktop and window station need to be created. If the impersonated user already has a desktop, the system will use the existing desktop. |
| <b>lpTitle</b>    | For console processes, this is the title displayed in the title bar if a new console window is created. If NULL, the name of the executable file is used as the window title instead. This parameter must be NULL for GUI or console processes that do not create a new console window.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>dwX</b>        | Ignored unless <code>dwFlags</code> specifies <code>STARTF_USEPOSITION</code> . Specifies the x offset, in pixels, of the upper left corner of a window if a new window is created. The offset is from the upper left corner of the screen. For GUI processes, the specified position is used the first time the new process calls the Windows API function <b>CreateWindow</b> to create an overlapped window if the x parameter of <b>CreateWindow</b> is <code>CW_USEDEFAULT</code> .                                                                                                                                                                                                                                                 |
| <b>dwY</b>        | Ignored unless <code>dwFlags</code> specifies <code>STARTF_USEPOSITION</code> . Specifies the y offset, in pixels, of the upper left corner of a window if a new window is created. The offset is from the upper left corner of the screen. For GUI processes, the specified position is used the first time the new process calls the Windows API function <b>CreateWindow</b> to create an overlapped window if the y parameter of <b>CreateWindow</b> is <code>CW_USEDEFAULT</code> .                                                                                                                                                                                                                                                 |

**Table 10** ▪ LAAW\_STARTUPINFO (cont.)

| Member                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dwXSize</b>         | Ignored unless dwFlags specifies STARTF_USESIZE. Specifies the width, in pixels, of the window if a new window is created. For GUI processes, this is used only the first time the new process calls the Windows API function <b>CreateWindow</b> to create an overlapped window if the nWidth parameter of <b>CreateWindow</b> is CW_USEDEFAULT.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>dwYSize</b>         | Ignored unless dwFlags specifies STARTF_USESIZE. Specifies the height, in pixels, of the window if a new window is created. For GUI processes, this is used only the first time the new process calls <b>CreateWindow</b> to create an overlapped window if the nHeight parameter of <b>CreateWindow</b> is CW_USEDEFAULT.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>dwXCountChars</b>   | Ignored unless dwFlags specifies STARTF_USECOUNTCHARS. For console processes, if a new console window is created, dwXCountChars specifies the screen buffer width in character columns. This value is ignored in a GUI process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>dwYCountChars</b>   | Ignored unless dwFlags specifies STARTF_USECOUNTCHARS. For console processes, if a new console window is created, dwYCountChars specifies the screen buffer height in character rows. This value is ignored in a GUI process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>dwFillAttribute</b> | <p>Ignored unless dwFlags specifies STARTF_USEFILLATTRIBUTE. Specifies the initial text and background colors if a new console window is created in a console application. These values are ignored in GUI applications. This value can be any combination of the following values: FOREGROUND_BLUE, FOREGROUND_GREEN, FOREGROUND_RED, FOREGROUND_INTENSITY, BACKGROUND_BLUE, BACKGROUND_GREEN, BACKGROUND_RED, and BACKGROUND_INTENSITY. For information on using these Windows constants, which are not defined in ISRTWindows.h, see Using Windows Constants in a Script. For example, the following combination of values produces red text on a white background:</p> <p>FOREGROUND_RED  BACKGROUND_RED  BACKGROUND_GREEN  BACKGROUND_BLUE</p> |

Table 10 • LAAW\_STARTUPINFO (cont.)

| Member             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dwFlags</b>     | <p>This is a bit field that determines whether certain STARTUPINFO members are used when the process creates a window. Any combination of the following values can be specified:</p> <ul style="list-style-type: none"> <li>● <b>STARTF_FORCEONFEEDBACK</b>—Indicates that the cursor is in feedback mode for two seconds after <b>LaunchApplication</b> or <b>LaunchAndAppAndWait</b> is called. If during those two seconds the process makes the first GUI call, the system gives five more seconds to the process. If during those five seconds the process shows a window, the system gives five more seconds to the process to finish drawing the window.</li> </ul> <p>The system turns the feedback cursor off after the first call to the Windows API function <b>GetMessage</b>, regardless of whether the process is drawing.</p> <ul style="list-style-type: none"> <li>● <b>STARTF_FORCEOFFFEEDBACK</b>—Indicates that the feedback cursor is forced off while the process is starting. The normal cursor is displayed.</li> <li>● <b>STARTF_RUNFULLSCREEN</b>—Indicates that the process should be run in full-screen mode, rather than in windowed mode.</li> </ul> <p>This flag is only valid for console applications running on an x86 computer.</p> <ul style="list-style-type: none"> <li>● <b>STARTF_USECOUNTCHARS</b>—If this value is not specified, the dwXCountChars and dwYCountChars members are ignored.</li> <li>● <b>STARTF_USEFILLATTRIBUTE</b>—If this value is not specified, the dwFillAttribute member is ignored.</li> <li>● <b>STARTF_USEPOSITION</b>—If this value is not specified, the dwX and dwY members are ignored.</li> <li>● <b>STARTF_USESHOWWINDOW</b>—If this value is not specified, the wShowWindow member is ignored.</li> <li>● <b>STARTF_USESIZE</b>—If this value is not specified, the dwXSize and dwYSize members are ignored.</li> <li>● <b>STARTF_USESTDHANDLES</b>—Sets the standard input, standard output, and standard error handles for the process to the handles specified in the hStdInput, hStdOutput, and hStdError members of the STARTUPINFO structure.</li> </ul> <p>LAAW_PARAMETERS.bInheritHandles must be set to TRUE for this to work properly.</p> <p>If this value is not specified, the hStdInput, hStdOutput, and hStdError members of the STARTUPINFO structure are ignored.</p> |
| <b>wShowWindow</b> | <p>Ignored unless dwFlags specifies STARTF_USESHOWWINDOW. The wShowWindow member can be any of the SW_ constants defined in Winuser.h. For GUI processes, wShowWindow specifies the default value the first time the Windows API function <b>ShowWindow</b> is called. The nCmdShow parameter of <b>ShowWindow</b> is ignored. In subsequent calls to <b>ShowWindow</b>, the wShowWindow member is used if the nCmdShow parameter of <b>ShowWindow</b> is set to SW_SHOWDEFAULT.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>cbReserved2</b> | Reserved; must be zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 10** ▪ LAAW\_STARTUPINFO (cont.)

| Member             | Description                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>lpReserved2</b> | Reserved; must be NULL.                                                                                                                                                        |
| <b>hStdInput</b>   | Ignored unless dwFlags specifies STARTF_USESTDHANDLES. Specifies a handle that will be used as the standard input handle to the process if STARTF_USESTDHANDLES is specified.  |
| <b>hStdOutput</b>  | Ignored unless dwFlags specifies STARTF_USESTDHANDLES. Specifies a handle that will be used as the standard output handle to the process if STARTF_USESTDHANDLES is specified. |
| <b>hStdError</b>   | Ignored unless dwFlags specifies STARTF_USESTDHANDLES. Specifies a handle that will be used as the standard error handle to the process if STARTF_USESTDHANDLES is specified.  |

## Example

To specify that the launched application should be displayed at coordinates (0,0), before calling **LaunchAppAndWait**, you would customize the structure as follows:

```
LAAW_STARTUPINFO.dwFlags = LAAW_STARTUPINFO.dwFlags | STARTF_USEPOSITION;
LAAW_STARTUPINFO.dwX = 0;
LAAW_STARTUPINFO.dwY = 0;
```

## MAINTENANCE

This system variable is set to TRUE if your installation program is running in maintenance mode, or set to FALSE for a first-time installation.

## MAINT\_OPTION

**Project** ▪ This information applies to InstallScript projects.

The MAINT\_OPTION system variable is set to one of the following values, corresponding to the maintenance option that you set for the Maintenance Experience setting in the General Information view:

- MAINT\_OPTION\_STANDARD
- MAINT\_OPTION\_MULTI\_INSTANCE
- MAINT\_OPTION\_NONE

## MEDIA

This system variable stores the name of the current file media library or script-created feature set. During setup initialization, MEDIA is assigned the value of 'DATA', which corresponds to the DATAx.cab file that was created by the media build. If you change the value of this system variable to refer to a script-created component set, you must change the value back to 'DATA' before calling [FeatureMoveData](#).

## MODE

The system variable MODE holds one of the following constant values (note that the value cannot be changed at run time):

**Table 11** • MODE

| Constant          | Meaning                                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SILENTMODE</b> | Indicates that Setup.exe is running in silent mode. (That is, the user ran Setup.exe with the /s argument.)                                                                                                      |
| <b>NORMALMODE</b> | Indicates Setup.exe is running in normal mode.                                                                                                                                                                   |
| <b>RECORDMODE</b> | Indicates Setup.exe is automatically generating a silent setup file (.iss file), which is a record of the setup input, by default in the Windows folder. (That is, when you run Setup.exe with the /r argument.) |

You can use the system variable MODE in if statements to control the flow of your script based on mode, as shown below:

```
if (MODE = SILENTMODE) then
    // Perform silent setup actions and events.
else
    // Perform normal setup actions and events.
endif;
```

**Note** • For a Basic MSI project, you can find if the user is running the installation in silent mode with the Windows Installer condition “UILevel=2”.

## MSI\_TARGETDIR

MSI\_TARGETDIR represents the destination of an administrative installation (when a user runs Setup.exe with the /a argument) for an InstallScript MSI project.

For a Basic MSI project, the TARGETDIR *property* (not the InstallScript variable) contains the destination of an administrative installation.

## MULTI\_INSTANCE\_COUNT

**Project** ▪ This information applies to InstallScript projects.

This system variable is set equal to the number of instances of the currently running multi-instance setup that are already installed on the target system. You cannot assign a new value to this system variable.

## PACKAGE\_LOCATION

**Project** ▪ The `PACKAGE_LOCATION` system variable applies to InstallScript projects only.

This system variable contains the fully qualified file name of the installation's self-extracting executable file if the installation is running from a self-extracting executable file that was created from within InstallShield, or a null string ("" ) value otherwise.

## PRODUCT\_GUID

This read-only system variable contains the GUID for the setup, which is initialized to the value of the project's ProductCode property. By default, `PRODUCT_GUID` is used as part of the `UNINSTALLKEY` variable and also as part of the `DISK1TARGET` and `SUPPORTDIR` directories.

## PRODUCT\_INSTALLED

**Project** ▪ This information applies to InstallScript projects.

This system variable is set to a non-zero value if a valid log file exists for the installation. If the installation is running with the standard maintenance option, this variable is equal to the `MAINTENANCE` system variable.

## PROGRAMFILES

The `PROGRAMFILES` system variable contains the fully qualified name of the folder defined by Windows to store applications. In English Windows, that folder is named Program Files, and it is located off the root of the drive on which Windows is installed. (In other language versions of Windows, the folder name is localized appropriately by default.) The program files folders is the recommended default location for application folders.

On 64-bit Windows systems, this folder is for 32-bit applications only and has the name Program Files (x86) by default; 64-bit applications should be installed to the `PROGRAMFILES64` folder.

**Tip** ▪ If your company distributes more than one application, you may prefer to create a company folder inside the program files folder and then create application folders within the company folder.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

**Project** ▪ During setup initialization in InstallScript installations, the value of the `PROGRAMFILES` variable is obtained by calling the Windows API function **SHGetSpecialFolderPath** with the `CSIDL_PROGRAM_FILES` parameter.

In Basic MSI and InstallScript MSI installations, the value of the `PROGRAMFILES` variable is initialized based on the Windows Installer property `ProgramFilesFolder`. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding `PROGRAMFILES` variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## PROGRAMFILES64

The `PROGRAMFILES64` system variable contains the fully qualified name of the folder defined by Windows to store 64-bit applications on a 64-bit system. (Note that 32-bit applications are stored under the `PROGRAMFILES` folder.) In English Windows, that folder is named Program Files, and it is located off the root of the drive on which Windows is installed. (In other language versions of Windows, the folder name is localized appropriately by default.) The program files folders are the recommended default locations for application folders.

**Tip** ▪ If your company distributes more than one application, you may prefer to create a company folder inside the program files folder and then create application folders within the company folder.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

**Project** ▪ During setup initialization in InstallScript installations, the value of the `PROGRAMFILES64` variable is obtained by calling the Windows API function **SHGetSpecialFolderPath** with the `CSIDL_PROGRAM_FILES` parameter from a 64-bit executable file.

In Basic MSI and InstallScript MSI installations, the value of the `PROGRAMFILES64` variable is initialized based on the Windows Installer property `ProgramFiles64Folder`. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding `PROGRAMFILES64` variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## REGDB\_OPTIONS

The REGDB\_OPTIONS system variable enables you to set various options for the general registry functions. The following table describes the options that you can specify:

**Table 12** • REGDB\_OPTIONS

| Option                                           | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>REGDB_OPTION_DISABLETEXTSUBS</b>              | Disables text substitutions in strings that are passed to registry functions. Use this option when working with registry function strings that contain opening angle brackets (<) and closing angle brackets (>) but that should not be interpreted as text substitutions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>REGDB_OPTION_NO_DELETE_OLD_MAJMIN_VERSION</b> | <p>Prevents the <b>MaintenanceStart</b> function from deleting the legacy values of the following constants:</p> <ul style="list-style-type: none"> <li>• <b>REGDB_VALUENAME_UNINSTALL_MAJORVERSION</b> (the major version value name under the application uninstallation key), whose value was MajorVersion for installations that were created with InstallShield 2009 and earlier</li> <li>• <b>REGDB_VALUENAME_UNINSTALL_MINORVERSION</b> (the minor version value name under the application uninstallation key), whose value was MinorVersion for installations that were created with InstallShield 2009 and earlier</li> </ul> <p>For more information, see the “Changes to the Major and Minor Version Registry Entries for the Uninstall Key of InstallScript Installations” section in Upgrading Projects from InstallShield 2009 or Earlier.</p> |
| <b>REGDB_OPTION_WOW64_64KEY</b>                  | <p>Specifies that all future general registry operations affect the 64-bit parts of the registry instead of the 32-bit parts of the registry (on a 64-bit system). Setting this option on a 32-bit system has no effect.</p> <p>For more information about installing to 64-bit registry locations, see Targeting 64-Bit Operating Systems with InstallScript Installations.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>REGDB_OPTION_USE_DEFAULT_OPTIONS</b>          | Resets (clears) all previously set options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

To add options, combine one or more options using bitwise OR (|) operator as shown:

```
REGDB_OPTIONS = REGDB_OPTIONS | REGDB_OPTION_WOW64_64KEY
```

To remove options, specify the option to remove using the bitwise AND (&) operator and the bitwise NOT (~) operator as shown:

```
REGDB_OPTIONS = REGDB_OPTIONS & ~REGDB_OPTION_WOW64_64KEY
```

**Note** ▪ When you enable the `REGDB_OPTION_WOW64_64KEY` option, this affects where registry entries from registry sets are created. For example, if this option is enabled when you call the `CreateRegistrySet` function, the registry set is created in the 64-bit part of the registry. If you enable this option for the specific 64-bit registry sets you want to install, it is recommended that you then disable the option so other registry entries or sets are not incorrectly created in the 64-bit part of the registry. For more information about installing to 64-bit registry locations, see *Targeting 64-Bit Operating Systems with InstallScript Installations*.

The InstallScript engine currently does not support installing Add or Remove Programs information for a product in the 64-bit part of the registry; therefore, the `REGDB_OPTION_WOW64_64KEY` option is not supported for the specific registry functions such as `CreateInstallationInfo`, `MaintenanceStart`, `RegDBGetItem`, `RegDBSetItem`, `RegDBGetAppInfo`, `RegDBSetAppInfo`, and `RegGetUninstCmdLine`.

## REINSTALLMODE

This system variable is non-zero if one of the reinstall functions has been called in an InstallScript installation—that is, if `FeatureReinstall`, `FeatureUpdate`, or `FeaturePatch` have been called in the current instance of the installation.

**Project** ▪ In an InstallScript MSI installation, this system variable is non-zero if the `FeatureReinstall` function is called. `FeatureUpdate` and `FeaturePatch` are not defined in an InstallScript MSI installation and should not be called.

## REMOVEALLMODE

**Project** ▪ This information applies to InstallScript projects.

This system variable is non-zero if the application is being completely uninstalled—that is, if `FeatureRemoveAll`, `FeatureRemoveAllInMedia`, or `FeatureRemoveAllInMediaAndLog` have been called in the current instance of the setup—and FALSE otherwise. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

**Note** ▪ To execute script code only when the application is being completely uninstalled, enclose the code in the following if-then statement:

```
if REMOVEALLMODE!=0 then
    /* this code is executed only during uninstallation */
endif;
```

To perform specific uninstallation actions when a particular component is uninstalled, override the component's `<ComponentName>_Uninstalling` event and perform the actions in this event.

## REMOVEONLY

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The REMOVEONLY system variable is set equal to a non-zero value if Setup.exe is run with the -removeonly option, and is set equal to FALSE otherwise. The default code for the OnMaintUIBefore event handler function conditionally displays the SdWelcomeMaint dialog, depending on the value of REMOVEONLY.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results.

## SELECTED\_LANGUAGE

**Project** ▪ The following project types support SELECTED\_LANGUAGE:

- *InstallScript*
- *InstallScript MSI*

The numeric system variable SELECTED\_LANGUAGE contains the ID of the language that the installation is using to display prompts and messages.

This system variable has a corresponding <SELECTED\_LANGUAGE> text substitution, which contains the value of SELECTED\_LANGUAGE formatted as a four-digit hexadecimal value (including the 0x prefix). For example, if SELECTED\_LANGUAGE is ISLANG\_ENGLISH\_UNITEDSTATES, the value of the text substitution is 0x0409.

## SHARED SUPPORTDIR

**Project** ▪ InstallScript projects support SHARED SUPPORTDIR.

The read-only variable SHARED SUPPORTDIR identifies the directory that contains all of the support files that are shared among an InstallScript installation and all of the InstallScript objects in that installation.

This system variable has a corresponding <SHARED SUPPORTDIR> text substitution.

## SHELL\_OBJECT\_FOLDER

**Project** ▪ The following project types support SHELL\_OBJECT\_FOLDER:

- *InstallScript*
- *InstallScript MSI*

The SHELL\_OBJECT\_FOLDER system variable is used to specify the name of a shell object folder—typically a Start Menu folder—at run time through script.

You can specify `SHELL_OBJECT_FOLDER` (for InstallScript or InstallScript MSI projects) or `<SHELL_OBJECT_FOLDER>` (for InstallScript projects) in the Display Name setting for a folder in the Shortcuts view. Then you can define the display name for the folder at run time by setting the `SHELL_OBJECT_FOLDER` variable in your script before the shortcut is created. The shortcut is typically created during file transfer.

**Project** - For InstallScript projects, you can specify either `<SHELL_OBJECT_FOLDER>` or `SHELL_OBJECT_FOLDER` in the Display Name setting. In both cases, text substitution is used. However, including the angle brackets—`<SHELL_OBJECT_FOLDER>`—is recommended.

For InstallScript MSI projects, you must specify `SHELL_OBJECT_FOLDER` (without the angle brackets).

To use this functionality in an InstallScript MSI installation, any letters that are specified for the Key Name setting of the folder in the Shortcuts view must be all uppercase (for example, `NEWFOLDER1`).

If the installation is not in maintenance mode, `SHELL_OBJECT_FOLDER` is initialized to the same value as `IFX_PRODUCT_NAME` during initialization of the InstallScript engine. Note that these variables are not synchronized once initialized; therefore, if you change one and want the other to change, you must change both manually. These types of manual changes are logged, and the changes are read from the log on subsequent maintenance operations. Therefore, a shortcut that uses the `SHELL_OBJECT_FOLDER` variable for its display name can be removed during uninstallation.

## SHOW\_PASSWORD\_DIALOG

**Project** - This information applies to InstallScript projects.

The `SHOW_PASSWORD_DIALOG` system variable is `TRUE` if the "Show Password dialog box during setup initialization" check box was checked in the Media Wizard's General Options panel or the media property sheet's General page, or `FALSE` otherwise.

## SRCDIR

This system variable contains the fully qualified path to the source folder that contains the Windows Installer package.

`SRCDIR` is initialized to the value of the Windows Installer property `SourceDir` when the sequence begins, and it cannot be assigned a new value in an InstallScript custom action.

## SRCDISK

This system variable contains the name of the drive with the source disk. During setup initialization, InstallShield assigns to `SRCDISK` the name of the drive that holds the disk containing the setup script file, `Setup.inx`. For example, if you start `Setup.exe` from a floppy disk in the A drive, then if that disk contains the file `Setup.inx`, InstallShield assigns the value `"A:"` to `SRCDISK`. Note that InstallShield includes the colon (:) with the drive letter.

**Note** ▪ If you intend to reference the root folder of the drive specified by this variable, you must append a backslash to it (specified as two backslashes). For example, if the value of `SRCDISK` is `A:`, the following statement refers to the root folder of that drive: `SRCDISK + "\\`".

## SUPPORTDIR

During setup initialization, the installation locates a folder on the target system into which it can copy temporary files and files that were compressed into your installation. The installation sets the value of `SUPPORTDIR` to the fully qualified path for that folder.

In addition, files that you add to the Language Independent (or language-specific) file list in the Support Files/ Billboards view of InstallShield are decompressed into `SUPPORTDIR` when the installation initializes, and they are deleted when the installation is complete.

To access a particular support file in an InstallScript project, use the `SUPPORTDIR` variable directly and then append the file name to the `SUPPORTDIR` value to obtain the complete path of the file. Following is an example of InstallScript event code:

```
prototype STRING GetSupportFilePathIS(STRING);
function STRING GetSupportFilePathIS(szSupportFile)
begin
    return SUPPORTDIR ^ szSupportFile;
end;
```

**Note** ▪ The value of the InstallScript variable `SUPPORTDIR` is not shared among InstallScript Object scripts or between InstallScript Object scripts and the main installation script.

**Project** ▪ Note that the value of the InstallScript system variable `SUPPORTDIR` is not the same as the value of the Windows Installer property `SUPPORTDIR`.

*In event-driven InstallScript, the `SUPPORTDIR` system variable points to the folder that contains support files.*

*In Basic MSI or InstallScript MSI projects, each InstallScript custom action initializes its own engine. Each engine does not know where the primary `SUPPORTDIR` is, and each engine does not extract its own private copy of the support files. For instructions on locating the extracted support files from a custom action, see [Placing Files in the .msi Database and Extracting Them During Run Time](#).*

## SYSINFO

During setup initialization, the installation sets the members of the `SYSINFO` structure variable to identify the operating platform of the target computer. By inspecting the values assigned to members of this variable, your script can determine information such as the following:

- The operating system
- The major and minor version number of the operating system
- The subversion of the operating system

- The version of Internet Explorer
- The latest service pack that is installed
- If the end user has administrator rights under Windows NT
- If the end user is a power user
- If the system is 64-bit
- If the system is a virtual machine
- The language IDs of the system language, user language, and operating system language

The following table shows the meaning of each SYSINFO member:

**Table 13** • SYSINFO Members

| Member                           | Meaning                                                                                                                                                         |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SYSINFO.bIntel</b>            | If TRUE, the processor is Intel.                                                                                                                                |
| <b>SYSINFO.bIsVirtualMachine</b> | If TRUE, a virtual machine is detected.<br><br>For more information, see <a href="#">Detecting Whether the Installation Is Being Run on a Virtual Machine</a> . |
| <b>SYSINFO.bIsWow64</b>          | If the installation is running on a 64-bit platform, this value is non-zero.                                                                                    |
| <b>SYSINFO.bShellExplorer</b>    | If TRUE, the shell is Explorer.                                                                                                                                 |
| <b>SYSINFO.bWinServer2003R2</b>  | If this member is TRUE, the operating system is Windows Server 2003 R2.                                                                                         |

| <b>SYSINFO.WINNT.bWinNT</b>                                         | If this member is TRUE, the operating system is Windows NT (includes Windows XP).                                                                                                                                                                                                                                                                                      |
| <b>SYSINFO.WINNT.bWinVista_Server2008 (SYSINFO.WINNT.bWinVista)</b> | <p>If either SYSINFO.WINNT.bWinVista_Server2008 or SYSINFO.WINNT.bWinVista is TRUE, the operating system is Windows Vista or Windows Server 2008.</p> <p>To distinguish between Windows Server 2008 and Windows Vista, check whether SYSINFO.nOSProductType is equal to VER_NT_WORKSTATION; for Windows Vista, this is TRUE; for Windows Server 2008, it is FALSE.</p> |
| <b>SYSINFO.WINNT.bWinXP</b>                                         | If this member is TRUE, the operating system is Windows XP.                                                                                                                                                                                                                                                                                                            |
| <b>SYSINFO.WINNT.bWinServer2003</b>                                 | If this member is TRUE, the operating system is Windows Server 2003 or Windows Server 2003 R2.                                                                                                                                                                                                                                                                         |
| <b>SYSINFO.WINNT.nServicePack</b>                                   | <p>The number of the installed service pack.</p> <p>The installation obtains this information by calling the Windows API <b>GetVersionEx</b> and reading the nServicePackMajor value.</p>                                                                                                                                                                              |
| <b>SYSINFO.WINNT.bWinServer2019</b>                                 | Returns TRUE in Windows Server 2019 else FALSE.                                                                                                                                                                                                                                                                                                                        |
| <b>SYSINFO.nOSBuildNo</b>                                           | Stores the operating system build number                                                                                                                                                                                                                                                                                                                               |
| <b>SYSINFO.nISOSL</b>                                               | Returns ISOSL_WIN10_SERVER2019 in Windows Server 2019.                                                                                                                                                                                                                                                                                                                 |

## Example

The following code fragment displays a message box if the operating system on the target system is Windows XP.

```
if (SYSINFO.WINNT.bWinXP) then
    MessageBox("Installing on Windows XP", INFORMATION);
```

```
endif;
```

## SYSPROCESSORINFO

During setup initialization, the installation sets the members of this structure variable to identify information about the processor of the target computer. By inspecting the values assigned to members of this variable, your script can determine information such as the number of processors on the system and the type of processor.

The following table shows the meaning of each SYSPROCESSORINFO member:

**Note** ▪ Each of these members corresponds to a member in the Windows *SYSINFO* structure. These are populated during initialization by calling the Windows API *GetSystemInfo* or *GetNativeSystemInfo* functions on 64-bit Windows systems. Consult the documentation on this structure in the MSDN Library. Also, as documented by Microsoft, using *nProcessorType* is not recommended. Use *nProcessorLevel* and *nProcessorArchitecture* instead.

**Table 14** ▪ SYSPROCESSORINFO

| Member                                         | Meaning                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SYSPROCESSORINFO.nProcessorArchitecture</b> | <p>Indicates the processor architecture. Possible values are the following:</p> <p><b>PROCESSOR_ARCHITECTURE_INTEL</b></p> <p><b>PROCESSOR_ARCHITECTURE_IA64</b></p> <p><b>PROCESSOR_ARCHITECTURE_AMD64</b></p> <p><b>PROCESSOR_ARCHITECTURE_UNKNOWN</b></p>                                                                                        |
|                                                | <p><b>Note</b> ▪ <i>InstallScript</i> includes constants for the most common values for this structure member. However, in unusual cases, this structure member could contain other values defined by Windows. Consult the Windows documentation on the corresponding <i>SYSINFO</i> member for more information on possible additional values.</p> |
| <b>SYSPROCESSORINFO.nNumberOfProcessors</b>    | Indicates the number of processors on the system.                                                                                                                                                                                                                                                                                                   |

Table 14 ■ SYSPROCESSORINFO (cont.)

| Member                                     | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SYSPROCESSORINFO.nProcessorType</b>     | <p>Indicates the processor type. Possible values are the following:</p> <p><b>PROCESSOR_INTEL_386</b></p> <p><b>PROCESSOR_INTEL_486</b></p> <p><b>PROCESSOR_INTEL_PENTIUM</b></p> <p><b>PROCESSOR_INTEL_IA64</b></p> <p><b>PROCESSOR_AMD_X8664</b></p> <p></p> <p><b>Note</b> ■ <i>InstallScript includes constants for the most common values for this structure member. However, in unusual cases, this structure member could contain other values defined by Windows. Consult the Windows documentation on the corresponding SYSINFO member for more information on possible additional values.</i></p> |
| <b>SYSPROCESSORINFO.nProcessorLevel</b>    | <p>Indicates the system's architecture-dependent processor level. This is often defined by the vendor and should be used for display purposes. See the Windows documentation on the SYSINFO structure for further information on the meaning of these members.</p>                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYSPROCESSORINFO.nProcessorRevision</b> | <p>Indicates the system's architecture-dependent processor revision. See the Windows documentation on the SYSINFO structure for further information on the meaning of these members.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## TARGETDIR

During setup initialization, the installation assigns to the system variable TARGETDIR the fully qualified path to a target folder on the hard disk. This folder will be the one containing the file Win.ini, usually the Windows folder. Some InstallScript functions use this variable when performing file operations. You must set this variable to the folder you want to target before calling these functions. The default code for the OnFirstUIBefore event handler function assigns a value to TARGETDIR.

The value of this system variable is shared among object scripts and between object scripts and the main setup script. The value you assign to this system variable in any script is the value it has in the subsequently executed code in any script (until its value is explicitly reset).

## TARGETDISK

During setup initialization, the installation assigns the name of the target disk drive to the system variable TARGETDISK. This drive will be the one containing the file Win.ini, usually the C: drive. Note that InstallShield includes the colon (:) with the drive letter.

**Note** ▪ If you intend to reference the root folder of the drive specified by this variable, you must append a backslash to it (specified as two backslashes). For example, if the value of `TARGETDISK` is `C:`, the following statement refers to the root folder of that drive: `TARGETDISK + "\\`.

## UNINST

**Project** ▪ The following project types support `UNINST`:

- `InstallScript`
- `InstallScript MSI`

The `UNINST` system variable is provided for compatibility with earlier versions of InstallShield software. It contains the command line that launches the copy of `Setup.exe` that was placed on the target system to perform uninstallation. The default value is:

```
<UNINSTALL_STRING> -uninst
```

If you use this command line, the installation runs the `OnUninstall` event when the installation is launched. For more details, review the `/uninst` command-line parameter information for `Setup.exe`.

This command line is placed in the appropriate registry value by the `DeinstallStart` function, which is provided for compatibility with previous versions of InstallShield software.

The value of this system variable is shared among object scripts and between object scripts and the main setup script.

You can append your own custom command line switches to `UNINST` for processing by your script's uninstallation code. If you do so, and you change the value of the system variable `DISK1TARGET`, be sure to change `DISK1TARGET` before appending to `UNINST`; `UNINST` incorporates `DISK1TARGET` and is automatically changed when you change `DISK1TARGET`.

## UNINSTALLKEY

**Project** ▪ This information applies to the following project types:

- `InstallScript`
- `InstallScript MSI`

*Note that project-specific differences are provided where applicable.*

The `UNINSTALLKEY` system variable contains the name of the registry key that is used to store your uninstallation information. The registry key is placed under `SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall`.

In an `InstallScript` installation, this key is placed under `HKEY_USER_SELECTABLE_AUTO`, which is controlled by the value of the `ALLUSERS` script variable. In an `InstallScript MSI` installation, this key is placed under `HKEY_LOCAL_MACHINE` if the installation is being run by an administrator; otherwise, it is placed under `HKEY_CURRENT_USER`.

In an InstallScript installation, the default value is **INSTANCE\_GUID**. In an InstallScript MSI installation, the default value of UNINSTALLKEY is **InstallShield\_{ProductCode}**.

To specify a different uninstallation key, assign a new value to UNINSTALLKEY in your script, as in the following example:

```
UNINSTALLKEY = "Sample App";
```

Note that to avoid conflicts with other installed applications, be sure to use a value that is unique to your application.

If the UNINSTALLKEY variable has been changed from the default value, the installation automatically creates an additional registry key for the product:

- **For InstallScript installations**—REGDB\_KEYPATH\_ISUNINSTINFO ^ INSTANCE\_GUID
- **For InstallScript MSI installations**—REGDB\_KEYPATH\_ISUNINSTINFO ^ [ProductGuid]

This key contains a single string value with the name **UninstallKey** (REGDB\_VALUENAME\_UNINSTALLKEY); the value data contains the name of the product's uninstall key as determined by the UNINSTALLKEY variable. This value can be used to allow other products to find and use the uninstall information for the product without the product's custom uninstall key.

## UNINSTALL\_DISPLAYNAME

This system variable contains the displayed name of your product in Add or Remove Programs. This value is typically the product name you specified in the General Information view.

To specify a different uninstallation display name, assign a new value to UNINSTALL\_DISPLAYNAME in your script before data transfer, as in the following:

```
UNINSTALL_DISPLAYNAME = "Sample App";
```

**Project** • UNINSTALL\_DISPLAYNAME is used only in InstallScript and InstallScript MSI installation projects. Basic MSI projects use the value of the ProductName property as the product's display name in Add or Remove Programs.

## UNINSTALL\_STRING

**Project** • The following project types support UNINSTALL\_STRING:

- InstallScript
- InstallScript MSI

The UNINSTALL\_STRING system variable contains the command line that launches the setup launcher, the installation's executable file, which was placed on the target system to perform uninstallation. The default value is:

```
<DISK1TARGET>\<DISK1SETUPEXENAME> -runfromtemp -l<SELECTED_LANGUAGE>
```

The setup launcher automatically writes the UNINSTALL\_STRING command line to the registry, unless you have hidden the Remove button (via the Disable Remove Button property) in Add or Remove Programs.

You can append your own custom command line switches to UNINSTALL\_STRING for processing by your script's uninstallation code.

## UPDATERMODE

The UPDATERMODE system variable applies to InstallScript projects only.

This system variable is set by the [OnSetUpdateMode](#) event handler function and is used by the OnShowUI event handler to call the appropriate UI event handlers.

## WINDIR

The WINDIR system variable contains the fully qualified name of the folder that contains the main operating environment, for example C:\Windows.

This system variable is read-only; if you attempt to assign a value to it, a compiler error results. The value of this system variable is shared among object scripts and between object scripts and the main setup script.

**Project** ▪ During setup initialization in InstallScript installations, the value of the WINDIR variable is obtained by calling the Windows API function **GetWindowsDirectory**.

In Basic MSI and InstallScript MSI installations, the value of the WINDIR variable is initialized based on the Windows Installer property WindowsFolder. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding WINDIR variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## WINDISK

The WINDISK system variable contains the ID of the disk drive that contains the main operating environment. This drive is the one that contains the Windows program—usually drive C. Note that the InstallScript engine includes the colon (:) with the drive letter.

**Note** ▪ If you intend to reference the root folder of the drive specified by this variable, you must append a backslash to it (specified as two backslashes). For example, if the value of WINDISK is C:, the following statement refers to the root folder of that drive: WINDISK + "\\\".

**Project** ▪ During setup initialization in InstallScript installations, the value of the WINDIR variable is obtained by calling the Windows API function **SHGetSpecialFolderPath** with the CSIDL\_WINDOWS parameter.

In Basic MSI and InstallScript MSI installations, the value of the WINDIR variable is obtained by calling the InstallScript function **GetDisk** with WINDIR; if that fails, this variable is initialized based on the Windows Installer

property `WindowsVolume`. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding `WINDIR` variable is empty in deferred, commit, and rollback custom actions. To learn more, see [Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions](#).

## WINSYSDIR

The `WINSYSDIR` system variable contains the name of the System32 folder. This folder is used to store application extensions (DLLs), device drivers, and other Windows system files, depending on the version of Windows.

On 64-bit Windows systems, this variable points to the folder that stores Windows system files that are used by 32-bit applications. This folder is named `SysWOW64`. There is a different Windows system folder for system files to be used by 64-bit applications; the system variable `WINSYSDIR64` provides access to this folder.

**Project** - During setup initialization in InstallScript installations on 32-bit systems, the value of the `WINSYSDIR` variable is obtained by calling the Windows API `GetSystemFolder`. During setup initialization in InstallScript installations on 64-bit systems, the value of the `WINSYSDIR` variable is obtained by calling the Windows API `GetSystemWow64Directory` from a 64-bit executable file.

In Basic MSI and InstallScript MSI installations on 32-bit systems, the value of the `WINSYSDIR` variable is initialized based on the Windows Installer property `SystemFolder`. On 64-bit systems, the value is initialized based on the Windows Installer property `System64Folder`. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding `WINSYSDIR` variable is empty in deferred, commit, and rollback custom actions. To learn more, see [Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions](#).

## WINSYSDIR64

The `WINSYSDIR64` system variable contains the name of the 64-bit System32 folder. This folder is used to store application extensions (DLLs), device drivers, and other Windows system files, depending on the version of Windows.

Although the `WINSYSDIR64` variable is set to the 64-bit System32 folder, 64-bit Windows includes functionality to automatically redirect 32-bit applications (such as the InstallScript engine) to the 32-bit `SysWOW64` folder. Therefore, if you are using InstallScript code to read or write to `WINSYSDIR64`, you may need to first disable file system redirection using the constant `WOW64FSREDIRECTION` with the functions `Disable` and `Enable`. Otherwise, reading from and writing to `WINSYSDIR64` are incorrectly redirected to the 32-bit `SysWOW64` folder. Since some Windows functionality that could be used by the installation requires that redirection be enabled to work, Windows documentation recommends that you disable redirection only for as long as necessary. It is recommended that you then enable file system redirection as soon as you have completed reading from or writing to `WINSYSDIR64`.

The example code below shows how to disable and enable redirection before and after transferring a file to the `WINSYSDIR64` through script:

```
Disable (WOW64FSREDIRECTION);
XCopyFile (SUPPORTDIR ^ "MyFile.dll", WINSYSDIR64, COMP_NORMAL);
Enable (WOW64FSREDIRECTION);
```

**Project** ▪ InstallScript projects have support for installing files to the 64-bit System32 folder without requiring any script modifications with WOW64FSREDIRECTION. If you have files that need to be installed to this location, you can add the files and registry data to a component, and select Yes for that component's 64-Bit Component setting. At run time, the installation automatically disables file system redirection for the System32 files. To learn more, see *Targeting 64-Bit Operating Systems with InstallScript Installations*.

During setup initialization in InstallScript installations on 64-bit systems, the value of the WINSYSDIR64 variable is obtained by calling the Windows API **GetSystemFolder** from a 64-bit executable file.

In Basic MSI and InstallScript MSI installations on 64-bit systems, the value of the WINSYSDIR64 variable is initialized based on the Windows Installer property System64Folder. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding WINSYSDIR variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

## WINSYSDISK

The WINSYSDISK system variable contains the name of the disk drive that contains the Windows system folder—usually the C: drive. This folder is used to store application extensions (DLLs), device drivers, and other Windows system files, depending on the version of Windows. Note that the InstallScript engine includes the colon (:) with the drive letter. For information about the Windows system folder, see the documentation for the InstallScript system variable **WINSYSDIR**.

**Note** ▪ If you intend to reference the root folder of the drive specified by this variable, you must append a backslash to it (specified as two backslashes). For example, if the value of WINSYSDISK is C:, the following statement refers to the root folder of that drive: WINSYSDISK + "\\".

**Project** ▪ During setup initialization in InstallScript installations, the value of the WINSYSDIR variable is obtained by calling the Windows API **GetSystemFolder**.

In Basic MSI and InstallScript MSI installations, the value of the WINSYSDIR variable is obtained by calling the InstallScript function **GetDisk** with WINSYSDIR; if that fails, this variable is initialized based on the Windows Installer property WindowsVolume. Note that deferred, commit, and rollback custom actions do not have access to this property. Therefore, the corresponding WINSYSDIR variable is empty in deferred, commit, and rollback custom actions. To learn more, see *Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions*.

# Preprocessor Directives

Preprocessor directives are instructions to the InstallScript compiler that are executed as the script is compiled. Preprocessor directives can instruct the compiler to include other source files in the compilation, to define constants, to include or exclude statements based on compile-time conditions, and to display a user-defined error message. Although InstallScript directives are similar to directives in the C language, they are not exactly alike.

Preprocessor directives begin with a pound sign (#) and can be inserted anywhere in a script. Each directive must appear on a line by itself and must *not* be terminated with a semicolon.

## Using Preprocessor Directives

Use the following guidelines when using preprocessor directives in your script. A preprocessor directive meets the following conditions:

- It does not end with a semicolon.
- It cannot line wrap.
- It must be less than 250 characters in length.

**Note** - The expressions used in conditional directives can include constants that have been defined with the **#define** directive. They cannot include variables.

## Using Boolean Operators with Preprocessor Directives

The following Boolean operators are supported in #if, #ifdef, #ifndef, and #elif statements:

- Logical OR ( || )
- Logical AND ( && )
- Relational ( =, !=, >, >=, <, <= )

## InstallScript-Supported Preprocessor Directives

InstallScript supports the following preprocessor directives:

**Table 1** - Preprocessor Directives

| Preprocessor Directive | Description                                                       |
|------------------------|-------------------------------------------------------------------|
| <b>#define</b>         | Creates a symbolic constant.                                      |
| <b>#elif</b>           | Combines #else and #if into one statement.                        |
| <b>#else</b>           | Indicates alternatives if the test fails.                         |
| <b>#endif</b>          | Ends a preprocessor conditional directive (#if, #ifdef, #ifndef). |
| <b>#error</b>          | Displays a user-defined error message.                            |

**Table 1** • Preprocessor Directives

| Preprocessor Directive | Description                                                    |
|------------------------|----------------------------------------------------------------|
| <b>#if</b>             | Compiles if the conditional statement is true.                 |
| <b>#ifdef</b>          | Compiles if a numeric constant is defined.                     |
| <b>#ifndef</b>         | Compiles if a numeric constant is not defined.                 |
| <b>#include</b>        | Includes the contents of another file.                         |
| <b>#undef</b>          | Undefines a constant that was defined previously with #define. |
| <b>#warning</b>        | Display a compiler warning and a user-defined error message.   |

## #define

Use #define to define a number or string constant. When you define a constant and assign it a value, InstallShield replaces the constant with that value wherever it appears. For example, the following #define statement sets the value of MAX\_SIZE to 145:

```
#define MAX_SIZE 145
```

The following example declares a string constant with the #define directive:

```
#define STR_MESSAGE "This is a message."
```

Once you have defined STR\_MESSAGE, you can use it anywhere in the script. A string message you want displayed in SprintfBox or MessageBox cannot be longer than 255 characters. If you want to display more than 255 characters, split your string into two or more parts before displaying it. The 255-character limit includes spaces, escape sequences, and other special characters.

**Note** • Another way to define constants is in the Preprocessor Defines field on the Compile tab of the Setup Settings dialog box. If you add or change a preprocessor define in the Setup Settings dialog box, you must recompile your setup before the changes will take effect.

## Restrictions

There are a few restrictions regarding the #define directive:

- InstallShield supports the use of #define to define only macros that involve the simple lexical substitution of a number or a string. You cannot define macros with expressions using multiple terms or operators.
- Constants you declare with a #define statement cannot begin with numbers.
- Many InstallShield functions use predefined constants. If you try to define one of the predefined constants, the InstallShield Script Compiler generates an error message.
- InstallShield assigns a value of zero (0) to an undefined constant.

## #elif

The `#elif` compile-time statement is similar in function to the `elseif` run-time statement. It combines the `#if` and `#else` statements, allowing you to specify another condition. For example:

```
#if (A = 1)
    // compile if A equals 1
    . . .
#elif (A = 2)
    // compile if A equals 2
    . . .
#elif (B = 3)
    // compile if B equals 3
    . . .
#else
    // if none of the #elif conditions are true, compile
    // the following portion
    . . .
#endif
```

---

**Note** ▪ When using `#elif`, end the section with only one `#endif`.

## #error

Use the `#error` directive to abort compilation and display a user-defined error message. The message to display must be entered immediately after `#error` and be separated from the directive by at least one space.

In the example below, the constant `PRODUCTID` must equal 1 or 2. If the value of `PRODUCTID` is not within that range, the constant `PRODUCTNAME` is not defined and a user-defined error message is displayed.

```
#define PRODUCTID 1

#if (PRODUCTID = 1)
    #define PRODUCTNAME "Lite"
#elif (PRODUCTID = 2)
    #define PRODUCTNAME "Professional"
#endif

#ifdef PRODUCTNAME
    #error PRODUCTID out of range.
#endif
```

## #if. . .#else. . .#endif

Use the `#if` statement to select which lines to compile. You can switch various sections of the installation on and off, making the script more flexible. The `#if` statement works in the same manner as the run-time `if` statement:

```
#if (A = 1)
    // compile if A equals 1
    . . .
#else
    // compile
```

```

    . . .
#endif

```

Keep in mind the following restrictions when using #if:

- Note that the format of the #if statement is also identical to that of the run-time if statement; you must end the #if statement with the keyword #endif.
- You can test only numeric constants with an #if or #elif statement.
- InstallScript allows nesting of #if statements up to a maximum of 10 levels.

## #ifdef and #ifndef

Use the #ifdef statement when you want to compile a section only if a specified expression has been defined with #define. Use #ifndef when you want to compile a section only if a specified expression has not been defined.

### Example

```

#ifdef A
    // Compile if A is defined.
    . . .
#endif

#ifndef A
    // Skip if A is defined; otherwise compile.
    . . .
#endif

#ifdef A    // Compile if A is defined.    . . .#endif
#ifndef A    // Skip if A is defined; otherwise
compile.    . . .#endif

```

You can also use #ifdef and #ifndef with #else and #elif:

```

#ifdef nFilePath
    //statements
#else
    //statements
#endif

```

**Note** ▪ Preprocessor defines can be entered in the Project Settings dialog box's Compile/Link tab's Preprocessor Defines edit box. If you add or change a preprocessor definition in the Project Settings dialog box, you must recompile your setup for the changes to take effect.

### Restrictions

Keep in mind the following restrictions when using #ifdef and #ifndef statements:

- You cannot place comments on the same line as #ifdef and #ifndef directives.
- Do not test a constant that has a value of 0 (zero) with an #ifdef or #ifndef statement.
- You can test only numeric constants with an #ifdef or #ifndef statement.

# #include

Use the `#include` statement to include the contents of another script in the main installation script. When you use `#include`, the compiler treats the additional source script as if it were part of the main installation script. Additional scripts, or include files, may contain variable declarations, other compiler directives, and program statements.

For example, you can create a separate file that contains all the user-defined constant definitions and then insert it into the script file using the `#include` statement. If you need to redefine any of the constants at a later date, they are all in one central location.

When you compile from the InstallShield interface, InstallShield searches for include script files in the following order:

1. The project's script file directory
2. The directories that are specified in the Include Paths setting on the Compile/Link tab of the Settings dialog box
3. The InstallShield include directory

If two include files share the same name but they are stored in different locations, InstallShield links to the one that it finds first, according to the aforementioned order. In addition, if an include file is specified by a relative path, InstallShield searches for the path relative to the aforementioned directories, in order.

If the include file is not in any of these locations, specify a fully qualified file name in the `#include` statement. When using the `#include` statement, specify a file name or path by enclosing the file name or path in double quotation marks ("filename").

Note the following details when you are using `#include` directives in your script:

- InstallShield does not handle paths with more than 260 characters, including the file name.
- InstallScript allows nesting of include files up to a maximum of eight levels.
- The InstallShield preprocessor does not interpret a backslash character in an `#include` directive as a control character; when specifying a path, use a single backslash instead of double backslashes to separate folder names.
- Do not include C language header files in the script. The InstallShield compiler does not recognize some of C's constructs. Create header files using InstallScript only.

The following example shows a section of an installation script that uses the `#include` statement to include the contents of `Support.rul` and other files. Each of the source scripts referenced by the `#include` statements has been written for a specific purpose and is then added to the script when the script is compiled:

```
//The following include file contains installation-specific routines.
#include "SUPPORT.RUL"
```

```
// Local include file containing variable and prototype declarations.
#include "DECLARE.RUL"
```

```
// Include scripts from the LIBRARY directory
#include "..\LIBRARY\SYCHK.H"
```

```
// Include scripts from the DIALOGS directory.
```

```
#include "..\DIALOGS\WELCOME\WELCOME.H"
#include "..\DIALOGS\REGINS\REGINS.H"
#include "..\DIALOGS\ICONS\ICONS.H"
```

## #undef

Use the #undef directive to undefine a constant that was previously defined with #define. If you specify a constant with this directive that was not previously defined with the #define directive, an error will occur when you attempt to compile your script. In the following example, two constants are defined; then, the first constant is undefined if the second has been defined:

```
#define NORMSETUP
#define BONUSPAK

. . .

#ifdef NORMSETUP
    MessageBox('Compiling for normal setup .',INFORMATION);
#else
    MessageBox('Compiling for super setup.',INFORMATION);
#endif

#ifdef BONUSPAK
    #undef NORMSETUP
#endif

#ifdef NORMSETUP
    MessageBox('Compiling for normal setup .',INFORMATION);
#else
    MessageBox('Compiling for super setup.',INFORMATION);
#endif
```

## #warning

Use the #warning directive to display a compiler warning and a user-defined error message. The message to be displayed must be entered immediately after #warning and be separated from the directive by at least one space.

In the example below, the constant PRODUCTID must equal 1 or 2. If the value of PRODUCTID is not within that range, the constant PRODUCTNAME is not defined and a user-defined warning message is displayed.

```
#define PRODUCTID 1
#if (PRODUCTID = 1)
    #define PRODUCTNAME "Lite"
#elif (PRODUCTID = 2)
    #define PRODUCTNAME "Professional"
#endif
#ifndef PRODUCTNAME
    #warning PRODUCTID out of range.
#endif
```

# Event Handlers

**Project** • InstallScript event handlers are available in the following project types:

- InstallScript
- InstallScript MSI

Some exceptions exist for an InstallScript package that is included in an Advanced UI or Suite/Advanced UI installation. These are described below.

## About Event Handlers

InstallScript installations are driven by the InstallScript engine, which generates a series of events in a specific order. These events trigger software handlers that execute installation instructions. For example, shortly after an installation is loaded, it generates an event called Begin, which triggers the execution of an event handler called OnBegin. This handler specifies the instructions to carry out when the Begin event occurs. Other events occur in the installation to trigger other handlers. Together, the event handlers perform the work of installing the application.

A portion of an InstallScript MSI installation is driven by the InstallScript engine, and a portion is driven by the Windows Installer engine. The portion that is driven by the InstallScript engine uses a series of event handlers, similar to InstallScript installations.

Several types of event handlers are available:

- Global Event Handlers
- Feature Event Handlers
- Miscellaneous Event Handlers
- Advanced Event Handlers

When you create an InstallScript or InstallScript MSI project, InstallShield generates a set of default global event handlers, each of which is a function that is written in the InstallScript language. Likewise, when you add features to your project, InstallShield generates a set of default event handlers for that feature. You can override or customize any or all of the event handlers.

It is important to note that, in an event-driven script, event-handler functions are called even if they do not explicitly appear in the InstallScript view.

## Order of Event Handlers

Global and feature event handlers are always called in a specific order; which event handlers are called depends on the type of installation (normal installation, maintenance installation, administrative installation, or patch installation). Because miscellaneous event handlers respond to events that may not happen during installation, they are not necessarily called in a specific order, if they are called at all.

**Project** • When an InstallScript MSI major upgrade is uninstalling an earlier version of a product, none of the InstallScript event handlers are called.

**First-Time Installations**

- [OnBegin](#)
- [OnCCPSearch](#)
- [OnAppSearch](#)
- [OnFirstUIBefore](#)
- [OnGeneratingMSIScript](#) (InstallScript MSI only)
- [OnMoving](#)
- feature Installing events
- [OnInstallFilesActionBefore](#)
- [OnGeneratedMSIScript](#) (InstallScript MSI only)
- [OnInstallFilesActionAfter](#)
- feature Installed events
- [OnMoved](#)
- [OnFirstUIAfter](#)
- [OnEnd](#)

**Resumed Installations**

- [OnResumeUIAfter](#) (InstallScript MSI only)
- [OnResumeUIBefore](#) (InstallScript MSI only)

**Maintenance Installations**

- [OnBegin](#)
- [OnMaintUIBefore](#)
- [OnGeneratingMSIScript](#) (InstallScript MSI only)
- [OnMoving](#)
- feature Installing or Uninstalling events
- [OnInstallFilesActionBefore](#)
- [OnInstallFilesActionAfter](#)
- feature Installed or Uninstalled events
- [OnMoved](#)
- [OnGeneratedMSIScript](#) (InstallScript MSI only)
- [OnMaintUIAfter](#)
- [OnEnd](#)

## Patch Installations

- [OnPatchUIBefore](#) (InstallScript MSI only)
- [OnGeneratingMSIScript](#) (InstallScript MSI only)
- [OnMoving](#)
- feature Installing or Uninstalling events
- [OnInstallFilesActionBefore](#)
- [OnInstallFilesActionAfter](#)
- feature Installed or Uninstalled events
- [OnMoved](#)
- [OnGeneratedMSIScript](#) (InstallScript MSI only)
- [OnPatchUIAfter](#) (InstallScript MSI only)

## Exceptions for an InstallScript Package That Is Included in an Advanced UI or Suite/ Advanced UI Installation

If you include an InstallScript installation as an InstallScript package in an Advanced UI or Suite/Advanced UI project, the Advanced UI or Suite/Advanced UI installation displays its own user interface (UI) while automatically suppressing the UI of the InstallScript package. To make these changes possible, the Advanced UI or Suite/Advanced UI installation uses several Advanced UI- or Suite/Advanced UI-specific InstallScript events and functions by default, and ignores some of the standard InstallScript events and functions. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

Thus, depending on the installation state (first-time installation, maintenance, or update), [OnSuiteShowUI](#) ignores the UI events such as [OnFirstUIBefore](#) and [OnFirstUIAfter](#) and instead calls the following events:

- **First-time installation**—[OnSuiteInstallBefore](#), [OnSuiteInstallAfter](#)
- **Maintenance**—[OnSuiteMaintBefore](#), [OnSuiteMaintAfter](#)
- **Update**—[OnSuiteUpdateBefore](#), [OnSuiteUpdateAfter](#)

All other events and event call sequencing in an InstallScript package that is launched from an Advanced UI or Suite/Advanced UI installation remain the same as in an InstallScript installation that is launched separately from an Advanced UI or Suite/Advanced UI installation, or that is launched as an executable package from an Advanced UI or Suite/Advanced UI installation.

# Event Handler Index

Event handlers are InstallScript functions that are called in response to events that occur during setup. The names of these handlers are reserved. (It is not necessary to prototype these functions in your script.)

**Project** - Some of the following event handlers only apply to InstallScript or InstallScript MSI projects. Some apply to both types. Refer to the Project Type column to determine which projects are supported.

**Table 1** - Event Handlers Index

| Event Handler                 | Project Type                     |
|-------------------------------|----------------------------------|
| <b>OnAbort</b>                | InstallScript, InstallScript MSI |
| <b>OnAdminInstallUIAfter</b>  | InstallScript MSI                |
| <b>OnAdminInstallUIBefore</b> | InstallScript MSI                |
| <b>OnAdminPatchUIAfter</b>    | InstallScript MSI                |
| <b>OnAdminPatchUIBefore</b>   | InstallScript MSI                |
| <b>OnAdvertisementAfter</b>   | InstallScript MSI                |
| <b>OnAdvertisementBefore</b>  | InstallScript MSI                |
| <b>OnAppSearch</b>            | InstallScript, InstallScript MSI |
| <b>OnBegin</b>                | InstallScript, InstallScript MSI |
| <b>OnCanceling</b>            | InstallScript, InstallScript MSI |
| <b>OnCCPSearch</b>            | InstallScript, InstallScript MSI |
| <b>OnCheckMediaPassword</b>   | InstallScript                    |
| <b>OnComponentError</b>       | InstallScript, InstallScript MSI |
| <b>OnCustomizeUninstInfo</b>  | InstallScript                    |
| <b>OnDIFxLogCallback</b>      | InstallScript                    |
| <b>OnEnd</b>                  | InstallScript, InstallScript MSI |
| <b>OnError</b>                | InstallScript MSI                |
| <b>OnException</b>            | InstallScript MSI                |
| <b>OnFileError</b>            | InstallScript                    |
| <b>OnFileLocked</b>           | InstallScript                    |
| <b>OnFileReadOnly</b>         | InstallScript                    |

**Table 1** ■ Event Handlers Index (cont.)

| Event Handler                      | Project Type                     |
|------------------------------------|----------------------------------|
| <b>OnFilesInUse</b>                | InstallScript MSI                |
| <b>OnFilterComponents</b>          | InstallScript, InstallScript MSI |
| <b>OnFirstUIAfter</b>              | InstallScript, InstallScript MSI |
| <b>OnFirstUIBefore</b>             | InstallScript, InstallScript MSI |
| <b>OnGeneratedMSIScript</b>        | InstallScript MSI                |
| <b>OnGeneratingMSIScript</b>       | InstallScript MSI                |
| <b>OnHelp</b>                      | InstallScript, InstallScript MSI |
| <b>OnIISComponentInstalled</b>     | InstallScript, InstallScript MSI |
| <b>OnIISInitialize</b>             | InstallScript, InstallScript MSI |
| <b>OnIISUninitialize</b>           | InstallScript, InstallScript MSI |
| <b>OnIISVRootUninstalling</b>      | InstallScript, InstallScript MSI |
| <b>OnInstalled</b>                 | InstallScript, InstallScript MSI |
| <b>OnInstalledFile</b>             | InstallScript                    |
| <b>OnInstalledFontFile</b>         | InstallScript                    |
| <b>OnInstallFilesActionAfter</b>   | InstallScript, InstallScript MSI |
| <b>OnInstallFilesActionBefore</b>  | InstallScript, InstallScript MSI |
| <b>OnInstalling</b>                | InstallScript, InstallScript MSI |
| <b>OnInstallingFile</b>            | InstallScript                    |
| <b>OnInternetError</b>             | InstallScript                    |
| <b>OnLaunchAppAndWaitCallback</b>  | InstallScript, InstallScript MSI |
| <b>OnLogonUserSetMsiProperties</b> | InstallScript MSI                |
| <b>OnMaintUIAfter</b>              | InstallScript, InstallScript MSI |
| <b>OnMaintUIBefore</b>             | InstallScript, InstallScript MSI |
| <b>OnMD5Error</b>                  | InstallScript                    |

**Table 1** ■ Event Handlers Index (cont.)

| Event Handler                    | Project Type                                                                                                                                                                   |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnMoved</b>                   | InstallScript, InstallScript MSI                                                                                                                                               |
| <b>OnMoveData</b>                | InstallScript                                                                                                                                                                  |

| <b>OnSQLServerInitializeMaint</b>   | InstallScript                    |
| <b>OnUninstall</b>                  | InstallScript, InstallScript MSI |
| <b>OnUnInstalled</b>                | InstallScript, InstallScript MSI |
| <b>OnUninstalledFile</b>            | InstallScript                    |
| <b>OnUnInstalling</b>               | InstallScript, InstallScript MSI |
| <b>OnUninstallingDIFxDriverFile</b> | InstallScript                    |
| <b>OnUninstallingFile</b>           | InstallScript                    |
| <b>OnUninstallingFontFile</b>       | InstallScript                    |
| <b>OnUpdateUIAfter</b>              | InstallScript                    |
| <b>OnUpdateUIBefore</b>             | InstallScript                    |
| <b>OnWarning</b>                    | InstallScript MSI                |
| <b>OnXMLComponentInstalled</b>      | InstallScript                    |
| <b>OnXMLComponentUninstalling</b>   | InstallScript                    |
| <b>OnXMLInitialize</b>              | InstallScript                    |
| <b>OnXMLUninitialize</b>            | InstallScript                    |

## Component Event Handlers

Windows Installer installations use features—not components—as the highest level of organization in your project. Therefore, component event handlers have been replaced with feature event handlers. In addition, all supported component functions now have feature equivalents that should be used. For more information, see [Feature Functions](#) and [Feature Event Handlers](#).

## Global Event Handlers

Global event handlers carry out processes required before and after feature installation and uninstallation. They include event handlers in the following categories:

**Table 2** • Global Event Handlers Categories

| Category                         | Description                                                                                                                              |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Initialization Handlers</b>   | Event handlers that are called directly by the installation engine.                                                                      |
| <b>Before Move Data Handlers</b> | Event handlers that are triggered before features are installed or uninstalled on the target computer.                                   |
| <b>Move Data Handlers</b>        | Event handlers that are triggered immediately before and immediately after features are installed or uninstalled on the target computer. |
| <b>After Data Move Handlers</b>  | Event handlers that are triggered after features are installed or uninstalled on the target computer.                                    |

## Initialization Handlers

The following event handlers are called directly by the installation engine in InstallScript projects:

**Table 3** • Initialization Handlers

| Event Handler               | Project Type                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnCheckMediaPassword</b> | InstallScript                    | Called directly by the framework during initiation to query the end user for the installation media's password if the password is not already in the installation log file (as it is if the installation is running as a maintenance installation or uninstallation) and you selected the "Show Password dialog box during setup initialization" check box in the Release Wizard's Password panel or set the Show Password Dialog property to Yes in the Releases view. |
| <b>OnFilterComponents</b>   | InstallScript, InstallScript MSI | Called directly by the framework to filter out components in each feature by language and platform. Override this event to perform custom filtering.                                                                                                                                                                                                                                                                                                                    |

**Table 3** • Initialization Handlers

| Event Handler                 | Project Type  | Description                                                                                                                                                   |
|-------------------------------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnIISCheckRequirements</b> | InstallScript | This event handler is obsolete.                                                                                                                               |
| <b>OnSetTARGETDIR</b>         | InstallScript | Called directly by the framework during initialization to initialize TARGETDIR to its default value.                                                          |
| <b>OnSetUpdateMode</b>        | InstallScript | Called directly by the framework during initialization to set the UPDATEMODE system variable appropriately to control which UI events are called by OnShowUI. |

## OnCheckMediaPassword

**Project** • This information applies to InstallScript projects.

The OnCheckMediaPassword event handler function is called directly by the setup engine. The handler's default code queries the end user for the setup's password if the password is not already in the setup log file (as it is if the setup is running as a maintenance setup or uninstallation) and you checked the "Show Password dialog box during setup initialization" check box in the Release Wizard's Password panel or set Show Password Dialog to Yes in the Release property sheet.

This event handler is called (when appropriate) in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

### Syntax

```
OnCheckMediaPassword ( );
```

### Parameters

None.

### Return Values

None.

## OnFilterComponents

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The OnFilterComponents event handler is called directly by the InstallScript engine to handle feature filtering—that is, the including and excluding of features' components in the file transfer based on their Language and Operating System settings.

## Syntax

```
OnFilterComponents ( );
```

## Parameters

None.

## Return Values

None.

## Additional Information

By default, OnFilterComponents calls [FeatureFilterLanguage](#) to exclude all components with languages other than the one specified by the [SELECTED\\_LANGUAGE](#) system variable, and calls [FeatureFilterOS](#) to exclude all components with operating systems other than the one specified by the [SYSINFO](#) variable's nISOSL member.

This event handler is not called in an installation that uses a procedural script (a script with a program...endprogram block).

## OnSetTARGETDIR

**Project** ▪ This information applies to InstallScript projects.

The OnSetTARGETDIR event handler function is called directly by the setup engine to set the value of the system variable TARGETDIR.

This event handler is called in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

## Syntax

```
OnSetTARGETDIR ( );
```

## Parameters

None.

## Return Values

None.

## Additional Information

- By default, in a first installation OnSetTARGETDIR sets TARGETDIR to the value that you specified in the TARGETDIR setting in the General Information view, or—if you did not specify a value in InstallShield—to <FOLDER\_APPLICATIONS>\<IFX\_COMPANY\_NAME>\<IFX\_PRODUCT\_NAME>. <FOLDER\_APPLICATIONS>, <IFX\_COMPANY\_NAME>, and <IFX\_PRODUCT\_NAME> are texts substitutions whose values are resolved when TARGETDIR is referenced; that is, if you change the value of the system variable IFX\_COMPANY\_NAME

or IFX\_PRODUCT\_NAME after OnSetTARGETDIR has been called, that change is reflected in subsequent references to TARGETDIR.

- A maintenance installation or uninstallation initializes TARGETDIR to the value that is stored in the log file, and by default OnSetTARGETDIR does not modify the value of TARGETDIR.

## OnSetUpdateMode

**Project** ▪ This information applies to InstallScript projects.

The OnSetUpdateMode event handler function is called directly by the setup engine to determine whether the setup is an update to an existing installation and set the value of the system variable UPDATEMODE accordingly.

This event handler is called (when appropriate) in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

### Syntax

```
OnSetUpdateMode ( );
```

### Parameters

None.

### Return Values

None.

## Before Move Data Handlers

The following event handlers are triggered before files are transferred to the target computer. Most of these events are also triggered during a maintenance setup.

**Table 4** ▪ Before Move Data Handlers

| Event Handler      | Project Type      | Description                                                                                                                                                                     |
|--------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnBegin</b>     | InstallScript     | In InstallScript projects: Called directly by the framework after Initialization events.                                                                                        |
|                    | InstallScript MSI | In InstallScript MSI projects: Responds to the Begin event, the first redefinable event in a setup.                                                                             |
| <b>OnAppSearch</b> | InstallScript     | In InstallScript projects: Called directly by the framework after OnBegin.                                                                                                      |
|                    | InstallScript MSI | In InstallScript MSI projects: Responds to the Application Search event. Code this handler in installations that must search for a specific application on the target computer. |

**Table 4** ▪ Before Move Data Handlers

| Event Handler          | Project Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>OnSQLServerInitialize</b>      | InstallScript | Called by OnFirstUIBefore to establish any connections necessary for SQL Server support. This function will initialize the SQL Server runtime and attempt to make any necessary SQL Server connections displaying a login dialog for each one.                                            |
| <b>OnSQLServerInitializeMaint</b> | InstallScript | Called by OnMaintUIBefore to establish any connections necessary for SQL Server support.                                                                                                                                                                                                  |
| <b>OnIISInitialize</b>            | InstallScript | <p>The OnIISInitialize event is called by OnFirstUIBefore to initialize the IIS run time.</p>  <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p> |
| <b>OnXMLInitialize</b>            | InstallScript | <p>The OnXMLInitialize event is called by OnFirstUIBefore to initialize the XML runtime.</p>  <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p> |

## OnAppSearch

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The OnAppSearch event handler responds to the Application Search event. Code this handler in setups that must search for a specific application on the target computer. Your code might, for example, call FindFile to locate a key file, or RegDBKeyExist to search for a registry entry.

The following OnAppSearch function aborts the installation if a file called Notepad.exe is not available in the user's Windows or WinNT folder, or in a subdirectory of it.

```
function OnAppSearch( )
    NUMBER nResult;
    STRING svIgnore;
begin
    nResult =
        FindAllFiles(WindowsFolder, "Notepad.exe",
                    svIgnore, RESET);

    if (nResult < 0) then
```

```

        MessageBox("Unable to find a qualifying program. " +
                    "Setup will now exit.", SEVERE);
        abort;
    endif;
end;

```

---

**Note** ▪ This event handler is not executed during a maintenance setup or uninstallation.

## OnBegin

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The OnBegin event handler responds to the Begin event, the first redefinable event in a setup. Code that must be executed before anything else in the script should be included in this handler. For example, you can verify that the user's machine meets your product's system requirements here.

OnBegin is prototyped for you when you include iswi.h or ifx.h in your script. Define OnBegin in your script as in the following example:

```

#include "iswi.h"

function OnBegin( )
    // local variables
begin
    // beginning code
end;

```

For example, an OnBegin function that verifies a particular registry key exists before continuing the installation might appear as follows:

```

// abort installation if HKLM\Software\InstallShield does not exist
function OnBegin( )
    NUMBER nReturn;
begin

    // set the root key
    RegDBSetDefaultRoot(HKEY_LOCAL_MACHINE);

    // check for the existence of the subkey
    nReturn = RegDBKeyExist("Software\\InstallShield");

    if (nReturn < 0) then
        MessageBox("Your system does not meet the system requirements. " +
                    "Setup will now exit.", SEVERE);
        abort;
    endif;

end;

```

Code in this event handler is always executed, even during a maintenance setup or uninstallation, unless you place it inside the following if-then structure:

```
if (!MAINTENANCE) then
    // non-maintenance code
endif;
```

The setup sets the system variable **MAINTENANCE** equal to FALSE the first time the setup is run, and TRUE every time the setup is run thereafter.

## OnCCPSearch

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The OnCCPSearch event handler responds to the Upgrade Compliance event. Code this handler in setups that must search for an application whose presence qualifies the end user to install your application. Your code might, for example, call FindFile to locate a specific file. Note that this event handler is not executed during a maintenance setup or uninstallation.

## OnFirstUIBefore

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

*If the InstallScript installation is included in an Advanced UI or Suite/Advanced UI project as an InstallScript package, the Advanced UI or Suite/Advanced UI installation does not call this event handler. For more information, see Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project.*

The OnFirstUIBefore event handler responds to the First UI Before event. It performs tasks that must take place before the installation of features for a first-time installation of an application.

Typically, this handler calls InstallScript functions for the following tasks:

- To set up the screen.
- To display dialogs that welcome the end user, display the software license, and show other information about the software to be installed.
- To get information from the end user—including user registration, the destination path (TARGETDIR in InstallScript projects and INSTALLDIR in InstallScript MSI projects), and the setup type.

## OnIISInitialize

**Project** ▪ This information applies to InstallScript projects.

The OnIISInitialize is called before OnMoving. You can override this for similar purposes as OnISVRootUninstalling, as well as add code that checks the version of IIS or makes custom IIS modifications before installing the web sites and virtual roots.

## OnMaintUIBefore

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

If the InstallScript installation is included in an Advanced UI or Suite/Advanced UI project as an InstallScript package, the Advanced UI or Suite/Advanced UI installation does not call this event handler. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

The OnMaintUIBefore event handler responds to the Maintenance UI Before event. It performs tasks that must take place before the reinstallation of features for a maintenance installation of an application.

## OnSQLLogin

**Project** ▪ This information applies to InstallScript MSI projects.

The OnSQLLogin event responds to the First UI Before event. This event handler function creates a dialog which is used by the script to specify SQL login credentials. These credentials include the login ID and password.

**Note** ▪ If you want to call a SQL built-in function before the OnSQLLogin event gets called, you need to first call the [SQLRTInitialize2](#) function. This is applicable to all SQL-related functions. To learn more, see [Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects](#).

## OnSQLServerInitialize

**Project** ▪ This information applies to InstallScript projects.

The OnSQLServerInitialize event is called by OnFirstUIBefore to establish any connections necessary for SQL Server support. This function will initialize the SQL Server runtime and attempt to make any necessary SQL Server connections, displaying a login dialog for each one. Parameter nBtn indicates whether NEXT or BACK was the result of the previously displayed dialog. It is for information purposes only.

If you are working on a script that had overridden OnFirstUIBefore when you upgraded to a newer version of InstallShield and your script is not calling OnSQLServerInitialize, then you should add the OnFirstUIBefore code to your script file.

---

**Note** ▪ If you want to call a SQL built-in function before the OnSQLServerInitialize event gets called, you need to first call the [SQLRTInitialize2](#) function. This is applicable to all SQL-related functions. To learn more, see [Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects](#).

## OnSQLServerInitializeMaint

---

**Project** ▪ This information applies to InstallScript projects.

The OnSQLServerInitializeMaint event is called by OnMaintUIBefore to establish any connections necessary for SQL Server support. This function will initialize the SQL Server runtime and attempt to make any necessary SQL Server connections using login credentials stored in the log file.

---

**Note** ▪ This event is not called automatically in a program...endprogram style installation.

## OnSuiteInstallBefore

---

**Project** ▪ This information applies to InstallScript projects.

The OnSuiteShowUI event calls the OnSuiteInstallBefore event. By default, OnSuiteInstallBefore is called to initialize information, such as the selection of features, that is necessary to perform file transfer.

---

**Note** ▪ This event is not called automatically in a program...endprogram style installation.

## OnSuiteMaintBefore

---

**Project** ▪ This information applies to InstallScript projects.

The OnSuiteShowUI event calls the OnSuiteMaintBefore event. By default, OnSuiteMaintBefore is called to initialize information, such as the selection of features, that is necessary to perform file transfer.

---

**Note** ▪ This event is not called automatically in a program...endprogram style installation.

## OnSuiteUpdateBefore

---

**Project** ▪ This information applies to InstallScript projects.

The OnSuiteShowUI event calls the OnSuiteUpdateBefore event. By default, OnSuiteUpdateBefore is called to initialize information, such as the selection of features, that is necessary to perform file transfer.

---

**Note** ▪ This event is not called automatically in a program...endprogram style installation.

## OnUpdateUIBefore

---

**Project** ▪ This information applies to InstallScript projects.

If the InstallScript installation is included in an Advanced UI or Suite/Advanced UI project as an InstallScript package, the Advanced UI or Suite/Advanced UI installation does not call this event handler. For more information, see *Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project*.

The OnUpdateUIBefore event handler function is called by the OnShowUI event handler to display the pre-file-transfer user interface for an update setup.

This event handler is not called in a setup that uses a procedural script (a script with a program...endprogram block).

### Syntax

```
OnUpdateUIBefore ( );
```

### Parameters

None.

### Return Values

None.

## OnXMLInitialize

---

**Project** ▪ This information applies to InstallScript projects.

The OnXMLInitialize event is called by OnFirstUIBefore to initialize the XML run time.

---

**Note** ▪ This event is not called automatically in a program...endprogram style installation.

## Move Data Handlers

The following event handlers are triggered immediately before, during, or immediately after the installation or uninstallation of all features on the target computer:

**Table 5 • Move Data Handlers**

| Event Handler                       | Project Type                       | Description                                                                                                                                                                                                                                                                                             |
|-------------------------------------|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnMoveData</b>                   | InstallScript                      | Called by OnShowUI to transfer files. The event handler's default code calls FeatureTransferData to transfer the files.                                                                                                                                                                                 |
| <b>OnCustomizeUninstInfo</b>        | InstallScript                      | Called by OnMoveData to customize the uninstall information after calling MaintenanceStart.                                                                                                                                                                                                             |
| <b>OnMoving</b>                     | InstallScript<br>InstallScript MSI | In InstallScript projects: Called as a result of the installation calling FeatureTransferData or Feature MoveData. The event is called before any file transfer operations occur.<br><br>In InstallScript MSI projects: Called just before the action GenerateMSIScript is executed.                    |
| <b>OnMoved</b>                      | InstallScript<br>InstallScript MSI | In InstallScript projects: Called directly by the framework after FeatureTransferData is called in the script and after data transfer.<br><br>In InstallScript MSI projects: Responds to the Moved event that is generated just after all features are installed or uninstalled on the target computer. |
| <b>OnInstallingFile</b>             | InstallScript                      | Called when a file is about to be installed as a result of FeatureTransferData or FeatureMoveData.                                                                                                                                                                                                      |
| <b>OnUninstallingFile</b>           | InstallScript                      | Called when a file is about to be uninstalled as a result of FeatureTransferData or FeatureMoveData.                                                                                                                                                                                                    |
| <b>OnUninstallingFontFile</b>       | InstallScript                      | Called when a font file logged by RegisterFontResource is uninstalled.                                                                                                                                                                                                                                  |
| <b>OnUninstallingDIFxDriverFile</b> | InstallScript                      | Called when a driver installed or preinstalled by the DIFxDriverPackageInstall or DIFxDriverPackagePreinstall functions is uninstalled with uninstall logging enabled.                                                                                                                                  |
| <b>OnInstalledFile</b>              | InstallScript                      | Called after a file is installed as a result of FeatureTransferData or FeatureMoveData.                                                                                                                                                                                                                 |
| <b>OnInstalledFontFile</b>          | InstallScript                      | Called after a file is installed that is listed in the media as a font file.                                                                                                                                                                                                                            |
| <b>OnUninstalledFile</b>            | InstallScript                      | Called after a file is uninstalled as a result of FeatureTransferData or FeatureMoveData.                                                                                                                                                                                                               |

**Table 5 •** Move Data Handlers (cont.)

| Event Handler                     | Project Type         | Description                                                                                                                                                                                                                                    |
|-----------------------------------|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnSQLComponentInstalled</b>    | InstallScript        | Called after each component is installed so any SQL scripts attached to that component can be run.<br>SQLComponentInstalled is called after each component is installed so any SQL scripts attached to that component can be run.              |
| <b>OnSQLComponentUninstalled</b>  | InstallScript        | Called after each component is uninstalled so any SQL scripts attached to that component can be run. The SQLComponentUninstalled event is called after each component is uninstalled so any SQL scripts attached to that component can be run. |
| <b>OnSQLBatchScripts</b>          | InstallScript        | Called automatically by the framework after file transfer.                                                                                                                                                                                     |
| <b>OnIISComponentInstalled</b>    | InstallScript        | IISComponentInstalled is called after each component is installed so that any IIS information attached to that component can be installed.                                                                                                     |
| <b>OnIISVRootUninstalling</b>     | InstallScript        | Called before each IISVRoot is removed.                                                                                                                                                                                                        |
| <b>OnXMLComponentInstalled</b>    | InstallScript        | ISXMLComponentInstall is called after each component is installed so that any XML information attached to that component can be installed.                                                                                                     |
| <b>OnXMLComponentUninstalling</b> | InstallScript        | XMLComponentUninstalling is called before each .xml file is removed.                                                                                                                                                                           |
| <b>OnNetApiCreateUserAccount</b>  | InstallScript        | Called before OnMoving event. This event handler function does nothing unless NetApiRT.obl is added before Isrt.obl in the list of linked libraries.                                                                                           |
| <b>OnGeneratedMSIScript</b>       | InstallScript<br>MSI | Responds to the MSI standard action LaunchConditions after it is executed.                                                                                                                                                                     |
| <b>OnGeneratingMSIScript</b>      | InstallScript<br>MSI | Responds to the MSI standard action LaunchConditions before it is executed.                                                                                                                                                                    |
| <b>OnInstallFilesActionBefore</b> | InstallScript<br>MSI | Responds to the InstallFiles event handler function before it is called.                                                                                                                                                                       |
| <b>OnInstallFilesActionAfter</b>  | InstallScript<br>MSI | Responds to the InstallFiles event handler function after it is called.                                                                                                                                                                        |

## OnCustomizeUninstInfo

**Project** ▪ This information applies to InstallScript projects.

The OnCustomizeUninstInfo event handler function is called by OnMoveData to customize the uninstall information after calling MaintenanceStart.

### Syntax

```
OnCustomizeUninstInfo ( );
```

### Parameters

None.

### Return Values

None.

## OnGeneratedMSIScript

**Project** ▪ This information applies to InstallScript MSI projects.

The OnGeneratedMSIScript event handler is called after the MSI standard action LaunchConditions is executed. This event handler does not contain any code by default; it is included for legacy installations.

## OnGeneratingMSIScript

**Project** ▪ This information applies to InstallScript MSI projects.

The OnGeneratingMSIScript event handler responds to the MSI standard action LaunchConditions before it is executed. This event handler does not contain any code by default; it is included for legacy installations.

## OnIISComponentInstalled

The OnIISComponentInstalled event handler function is called after each component is installed so any IIS information attached to that component can be installed.

### Syntax

```
OnIISComponentInstalled ( szComponent );
```

## Parameters

**Table 6** • OnIISComponentInstalled Parameters

| Parameter          | Description                                                                 |
|--------------------|-----------------------------------------------------------------------------|
| <b>szComponent</b> | This parameter will have the name of the component that has been installed. |

## Return Values

This event handler function should return ISERR\_SUCCESS currently in all cases.

## OnIISVRootUninstalling

The OnIISVRootUninstalling event is called before each Virtual Directory is removed. You can check conditions related to IIS in your script, and then call abort() to stop the setup.

## OnInstalledFile

**Project** ▪ This information applies to InstallScript projects.

The OnInstalledFile event handler function is called after a file is installed as a result of FeatureTransferData or FeatureMoveData.

## Syntax

```
OnInstalledFile ( szFilename );
```

## Parameters

**Table 7** • OnInstalledFile Parameters

| Parameter         | Description                                                               |
|-------------------|---------------------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified file name of the file that was transferred. |

## Return Values

None.

## OnInstalledFontFile

**Project** ▪ This information applies to InstallScript projects.

The OnInstalledFontFile event handler function is called after a file is installed that is listed in the media as a font file.

## Syntax

```
OnInstalledFontFile ( pFontFileInfo );
```

## Parameters

**Table 8 • OnInstalledFontFile Parameters**

| Parameter            | Description                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>pFontFileInfo</b> | Pointer to a <a href="#">_FONTFILEINFO structure</a> that gives information about the font file that is being installed. |

## Return Values

None.

## OnInstallFilesActionAfter

The OnInstallFilesActionAfter event handler is called just after the standard Windows Installer action InstallFiles is performed.

## OnInstallFilesActionBefore

The OnInstallFilesActionBefore event handler is called just before the standard Windows Installer action InstallFiles is performed.

## OnInstallingFile

**Project** • This information applies to InstallScript projects.

The OnInstallingFile event handler function is called when a file is about to be installed as a result of FeatureTransferData or FeatureMoveData.

Code in this event handler is always executed, even during a maintenance setup, unless you place it inside the following if-then structure:

```
if !MAINTENANCE then
    \\ non-maintenance code
endif;
```

## Syntax

```
OnInstallingFile ( szFilename );
```

## Parameters

**Table 9** • OnInstallingFile Parameters

| Parameter         | Description                                                                          |
|-------------------|--------------------------------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified file name of the file that is about to be transferred. |

## Return Values

None.

## OnMoved

In InstallScript projects, OnMoved is called as a result of the installation calling FeatureTransferData or FeatureMoveData. The event is called when all file transfer operations are completed except for batch self-registration. In InstallScript MSI projects, OnMoved is called just before the action GenerateMSIScript is executed.

Code in this event handler is always executed, even during a maintenance setup or uninstallation, unless you place it inside the following if-then structure:

```
if (!MAINTENANCE) then
    // non-maintenance code
endif;
```

## OnMoveData

**Project** • This information applies to InstallScript projects.

The OnMoveData event handler function is called by the OnShowUI event handler to handle the file transfer. By default, OnMoveData calls FeatureTransferData to transfer the files.

This event handler is not called in a setup that uses a procedural script (a script with a program...endprogram block).

## Syntax

```
OnMoveData ( );
```

## Parameters

None.

## Return Values

None.

## OnMoving

In InstallScript projects, OnMoving is called as a result of the installation calling FeatureTransferData or FeatureMoveData. The event is called before any file transfer operations occur. In InstallScript MSI projects, OnMoving is called just before the action GenerateMSIScript is executed.

Code in this event handler is always executed, even during a maintenance setup, unless you place it inside the following if-then structure:

```
if !MAINTENANCE then
    \\ non-maintenance code
endif;
```

## OnNetApiCreateUserAccount

The OnNetApiCreateUserAccount event handler function is called before the OnMoving event. This event handler function does nothing unless you add NetApiRT.obl before Isrt.obl in the list of linked libraries.

### Syntax

```
OnNetApiCreateUserAccount()
```

### Parameters

None

### Return Values

This event handler function should always return ISERR\_SUCCESS.

### Additional Information

#### Task

**To add NetApiRT.obl to the list of linked libraries:**

1. On the **Build** menu, click **Settings**. The **Settings** dialog box opens.
2. In the **Libraries (.obl)** box, enter **NetApiRT.obl**. Note that it must be listed before Isrt.obl.

The path to NetApiRT.obl is as follows:

```
<ISProductFolder>\Script\ISRT\Lib\NetApiRT.obl
```

## OnSQLBatchScripts

The OnSQLBatchScripts event is called automatically by the framework after file transfer.

## OnSQLComponentInstalled

**Project** ▪ This information applies to InstallScript projects.

The OnSQLComponentInstalled event is called after each component is installed so any SQL scripts attached to that component can be run. SQLComponentInstalled is called after each component is installed so any SQL scripts attached to that component can be run.

## OnSQLComponentUninstalled

**Project** ▪ This information applies to InstallScript projects.

The SQLComponentUninstalled event is called after each component is uninstalled so any SQL scripts attached to that component can be run. The SQLComponentUninstalled event is called after each component is uninstalled so any SQL scripts attached to that component can be run. szComponent will have the name of the component that has been installed.

## OnUninstalledFile

**Project** ▪ This information applies to InstallScript projects.

The OnUninstalledFile event handler function is called after a file is uninstalled as a result of FeatureTransferData or FeatureMoveData.

### Syntax

```
OnUninstalledFile ( szFilename );
```

### Parameters

**Table 10** ▪ OnUninstalledFile Parameters

| Parameter  | Description                                                               |
|------------|---------------------------------------------------------------------------|
| szFilename | Specifies the fully qualified file name of the file that was uninstalled. |

### Return Values

None.

## OnUninstallingFile

**Project** ▪ This information applies to InstallScript projects.

The OnUninstallingFile event handler function is called when a file is about to be uninstalled as a result of FeatureTransferData or FeatureMoveData.

Code in this event handler is always executed, even during a maintenance setup, unless you place it inside the following if-then structure:

```

if !MAINTENANCE then
    \\ non-maintenance code
endif;

```

## Syntax

```
OnUninstallingFile ( szFilename );
```

## Parameters

**Table 11** ▪ OnUninstallingFile

| Parameter         | Description                                                                          |
|-------------------|--------------------------------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified file name of the file that is about to be uninstalled. |

## Return Values

None.

## OnUninstallingDIFxDriverFile

**Project** ▪ This information applies to *InstallScript* projects.

The OnUninstallingDIFxDriverFile event handler function is called when a driver installed or preinstalled by the DIFxDriverPackageInstall or DIFxDriverPackagePreinstall functions is uninstalled with uninstall logging enabled.

By default, the event uninstalls the driver using the DIFxDriverPackageUninstall function.

## Syntax

```
OnUninstallingDIFxDriverFile ( byval string szDriver );
```

## Parameters

**Table 12** ▪ OnUninstallingDIFxDriverFile

| Parameter       | Description                                              |
|-----------------|----------------------------------------------------------|
| <b>szDriver</b> | The complete path and file of the installed driver file. |

## Return Values

None.

## OnUninstallingFontFile

**Project** ▪ This information applies to InstallScript projects.

The OnUninstallingFontFile event handler function is called when a font file logged by RegisterFontResource is uninstalled.

### Syntax

```
OnUninstallingFontFile ( pFontFileInfo );
```

### Parameters

**Table 13** ▪ OnUninstallingFontFile

| Parameter            | Description                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>pFontFileInfo</b> | Pointer to a <a href="#">_FONTFILEINFO structure</a> that gives information about the font file that is being uninstalled. |

### Return Values

None.

## OnXMLComponentInstalled

OnXMLComponentInstalled is the event handler function associated with the ISXMLComponentInstall event. The ISXMLComponentInstall event is called after each component is installed so that any XML information attached to that component can be installed.

### Syntax

```
OnXMLComponentInstalled ( szComponent );
```

### Parameters

**Table 14** ▪ OnXMLComponentInstalled

| Parameter          | Description                                                                 |
|--------------------|-----------------------------------------------------------------------------|
| <b>szComponent</b> | This parameter will have the name of the component that has been installed. |

### Return Values

This event handler function should return ISERR\_SUCCESS currently in all cases.

## OnXMLComponentUninstalling

OnXMLComponentUninstalling is the event handler function associated with the XMLRTComponentUninstall event. The XMLRTComponentUninstall event is called before each .xml file is removed.

### Syntax

```
OnXMLComponentUninstalling ( szXmlComponent )
```

### Parameters

**Table 15** ▪ OnXMLComponentUninstalling

| Parameter             | Description                                                                 |
|-----------------------|-----------------------------------------------------------------------------|
| <b>szXmlComponent</b> | This parameter will have the name of the component that has been installed. |

### Return Values

This event handler function should return ISERR\_SUCCESS currently in all cases.

## After Data Move Handlers

The following event handlers are triggered after files and other data are transferred to the target computer:

**Table 16** ▪ After Data Move Handlers

| Event Handler         | Project Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnFirstUIAfter</b> | InstallScript<br>InstallScript MSI | <p>In InstallScript projects: The OnFirstUIAfter event called by OnShowUI after the file transfer of the setup when the setup is running in first install mode. By default this event displays UI that informs the end user that the setup has been completed successfully.</p> <div>  </div> <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p> <p>In InstallScript MSI projects: Responds to the First UI After event.</p> |

**Table 16** ▪ After Data Move Handlers (cont.)

| Event Handler              | Project Type                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnMaintUIAfter</b>      | InstallScript<br>InstallScript MSI | <p>In InstallScript projects: The OnMaintUIAfter event called by OnShowUI after the file transfer of the setup when the setup is running in maintenance mode. By default this event displays UI that informs the end user that the maintenance setup has been completed successfully.</p> <p></p> <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p> <p>In InstallScript MSI projects: Responds to the Maintenance UI After event.</p> |
| <b>OnUpdateUIAfter</b>     | InstallScript                      | <p>The OnUpdateUIAfter event called by OnShowUI after the file transfer of the setup when the setup is running in update mode. By default this event displays UI that informs the end user that the maintenance setup has been completed successfully. This event is not automatically called in a program.</p>                                                                                                                                                                                                                                                                |
| <b>OnEnd</b>               | InstallScript<br>InstallScript MSI | <p>In InstallScript projects: The OnEnd event is called at the end of the setup. This event is not called if the setup is aborted.</p> <p>In InstallScript MSI projects: Responds to the End event, the last redefinable event in a setup.</p>                                                                                                                                                                                                                                                                                                                                 |
| <b>OnSuiteInstallAfter</b> | InstallScript                      | <p>The OnSuiteShowUI event calls the OnSuiteInstallAfter event after file transfer has completed during an installation.</p> <p></p> <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p>                                                                                                                                                                                                                                              |
| <b>OnSuiteMaintAfter</b>   | InstallScript                      | <p>The OnSuiteShowUI event calls the OnSuiteMaintAfter event after file transfer has completed during maintenance.</p> <p></p> <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p>                                                                                                                                                                                                                                                    |

**Table 16** ▪ After Data Move Handlers (cont.)

| Event Handler             | Project Type  | Description                                                                                                                                                                                                                                                                                                        |
|---------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnSuiteUpdateAfter</b> | InstallScript | <p>The OnSuiteShowUI event calls the OnSuiteUpdateAfter event after file transfer has completed during an upgrade.</p>  <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p> |
| <b>OnIISUninitialize</b>  | InstallScript | <p>The OnIISUninitialize event is called by OnMoveDataAfter to initialize the IIS runtime.</p>  <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p>                         |
| <b>OnXMLUninitialize</b>  | InstallScript | <p>The OnXMLUninitialize event is called by OnMoveDataAfter to initialize the XML runtime.</p>  <p><b>Note</b> ▪ This event is not called automatically in a program...endprogram style installation.</p>                         |

## OnEnd

The OnEnd event handler responds to the End event, the last redefinable event in a setup. You can place any required cleanup code in the OnEnd function.

OnEnd is prototyped for you when you include ifx.h or iswi.h in your script. Define OnEnd in your script as in the following example:

```
#include "iswi.h"

function OnEnd( )
    // local variables
begin
    // cleanup code
end;
```

Code in this event handler is always executed, even during a maintenance setup, unless you place it inside the following if-then structure:

```
if !MAINTENANCE then
    \\ non-maintenance code
endif;
```

## OnFirstUIAfter

---

**Project** ▪ If the InstallScript installation is included in an Advanced UI or Suite/Advanced UI project as an InstallScript package, the Advanced UI or Suite/Advanced UI installation does not call this event handler. For more information, see *Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project*.

The OnFirstUIAfter event handler responds to the First UI After event. It performs tasks that must take place after the installation of features for a first installation of an application.

## OnIISUninitialize

The OnIISUninitialize event is called by OnMoveDataAfter to initialize the IIS runtime. This event will not be called automatically in an endprogram style installation.

## OnMaintUIAfter

---

**Project** ▪ If the InstallScript installation is included in an Advanced UI or Suite/Advanced UI project as an InstallScript package, the Advanced UI or Suite/Advanced UI installation does not call this event handler. For more information, see *Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project*.

The OnMaintUIAfter event handler responds to the Maintenance UI After event. It performs tasks that must take place after the reinstallation of features for a maintenance installation of an application.

## OnSuiteInstallAfter

---

**Project** ▪ This information applies to InstallScript projects.

The OnSuiteShowUI event calls the OnSuiteInstallAfter event after file transfer has completed during an installation.

---

**Note** ▪ This event is not called automatically in a program...endprogram style installation.

## OnSuiteMaintAfter

---

**Project** ▪ This information applies to InstallScript projects.

The OnSuiteShowUI event calls the OnSuiteMaintAfter event after file transfer has completed during maintenance.

---

**Note** ▪ This event is not called automatically in a `program...endprogram` style installation.

## OnSuiteUpdateAfter

---

**Project** ▪ This information applies to InstallScript projects.

The OnSuiteShowUI event calls the OnSuiteUpdateAfter event after file transfer has completed during an upgrade.

---

**Note** ▪ This event is not called automatically in a `program...endprogram` style installation.

## OnUpdateUIAfter

---

**Project** ▪ If the InstallScript installation is included in an Advanced UI or Suite/Advanced UI project as an InstallScript package, the Advanced UI or Suite/Advanced UI installation does not call this event handler. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

The OnUpdateUIAfter event handler function is called by the OnShowUI event handler to display the post-file-transfer user interface for an update setup.

This event handler is not called in a setup that uses a procedural script (a script with a `program...endprogram` block).

### Syntax

```
OnUpdateUIAfter ( );
```

### Parameters

None.

### Return Values

None.

## OnXMLUninitialize

The OnXMLUninitialize event is called by OnMoveDataAfter to initialize the XML runtime. This event will not be called automatically in an endprogram style installation.

# Feature Event Handlers

Feature event handlers carry out processes required just before and just after the installation or uninstallation of a single feature. The number of feature events and handlers depends on the number of features in your project.

To create an event handler function for a feature, select the feature name from the left event-category list, and select the event you want from the right event list. InstallShield creates a second InstallScript file, called `FeatureEvents.ru1`, in the InstallScript view.

Note that if you change the default feature event handler code in `FeatureEvents.ru1`, you must put the following statement in `Setup.ru1` to include your changes in the installation:

```
#include "FeatureEvents.ru1"
```

Following is a list of the feature event handlers.

**Table 17** • Feature Event Handlers

| Event Handler         | Project Type      | Description                                                                                                                                               |
|-----------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnInstalled</b>    | InstallScript     | In InstallScript projects: Runs in response to the Installed event that is generated just after the applicable feature is installed on the target system. |
|                       | InstallScript MSI | In InstallScript MSI projects: Runs just after Windows Installer transfers the files to the target system.                                                |
| <b>OnInstalling</b>   | InstallScript     | In InstallScript projects: Runs in response to the Installing event that is generated just before the feature is installed on the target system.          |
|                       | InstallScript MSI | In InstallScript MSI projects: Runs just before Windows Installer transfers the files to the target system.                                               |
| <b>OnUninstalled</b>  | InstallScript     | In InstallScript projects: Runs in response to the UnInstalled event that is generated just after the feature is removed from the target system.          |
|                       | InstallScript MSI | In InstallScript MSI projects: Runs just after Windows Installer removes the files from the target system.                                                |
| <b>OnUninstalling</b> | InstallScript     | In InstallScript projects: Runs in response to the UnInstalling event that is generated just before the feature is removed from the target system.        |
|                       | InstallScript MSI | In InstallScript MSI projects: Runs just before Windows Installer removes the files from the target system.                                               |

**Project** • Because Windows Installer controls the installation of features in InstallScript MSI installations, the order in which feature event-handler functions are called cannot be specified. In addition, feature events are not launched until all features are copied to the target system.

Also note that feature-uninstallation event handlers (*OnUninstalling* and *OnUnInstalled*) are not called during rollback.

## OnInstalled

---

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

In InstallScript projects, the OnInstalled feature event handler runs in response to the Installed event that is generated just after the applicable feature is installed on the target system.

In InstallScript MSI projects, the OnInstalled feature event handler runs just after Windows Installer transfers the files to the target system.

The OnInstalled feature event handler is listed in the InstallScript code in the following format:

```
MyFeatureName_Installed()
```

---

**Project** ▪ Because Windows Installer controls the installation of features in InstallScript MSI installations, the order in which feature event-handler functions are called cannot be specified. In addition, feature events are not launched until all features are copied to the target system.

Also note that feature-uninstallation event handlers (OnUninstalling and OnUninstalled) are not called during rollback.

## OnInstalling

---

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

In InstallScript projects, the OnInstalling feature event handler runs in response to the Installing event that is generated just before the feature is installed on the target system.

In InstallScript MSI projects, the OnInstalling feature event handler runs just before Windows Installer transfers the files to the target system.

The OnInstalling feature event handler is listed in the InstallScript code in the following format:

```
MyFeatureName_Installing()
```

---

**Project** ▪ Because Windows Installer controls the installation of features in InstallScript MSI installations, the order in which feature event-handler functions are called cannot be specified. In addition, feature events are not launched until all features are copied to the target system.

Also note that feature-uninstallation event handlers (OnUninstalling and OnUninstalled) are not called during rollback.

## OnUnInstalled

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

In InstallScript projects, the OnUnInstalled feature event handler runs in response to the UnInstalling event that is generated just before the feature is removed from the target system.

In InstallScript MSI projects, the OnUnInstalled feature event handler runs just before Windows Installer removes the files from the target system.

The OnUnInstalled feature event handler is listed in the InstallScript code in the following format:

```
MyFeatureName_UnInstalled()
```

**Project** ▪ Because Windows Installer controls the installation of features in InstallScript MSI installations, the order in which feature event-handler functions are called cannot be specified. In addition, feature events are not launched until all features are copied to the target system.

Also note that feature-uninstallation event handlers (OnUnInstalling and OnUnInstalled) are not called during rollback.

## OnUnInstalling

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

In InstallScript projects, the OnUnInstalling feature event handler runs in response to the UnInstalling event that is generated just before the feature is removed from the target system.

In InstallScript MSI projects, the OnUnInstalling feature event handler runs just before Windows Installer removes the files from the target system.

The OnUnInstalling feature event handler is listed in the InstallScript code in the following format:

```
MyFeatureName_UnInstalling()
```

**Project** ▪ Because Windows Installer controls the installation of features in InstallScript MSI installations, the order in which feature event-handler functions are called cannot be specified. In addition, feature events are not launched until all features are copied to the target system.

Also note that feature-uninstallation event handlers (OnUnInstalling and OnUnInstalled) are not called during rollback.

# Miscellaneous Event Handlers

Miscellaneous event handlers are triggered by unscheduled events during an installation, such as the end user exiting the installation.

**Table 18** • Miscellaneous Event Handlers

| Event Handler                 | Project Type                        | Description                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnAbort</b>                | InstallScript,<br>InstallScript MSI | In InstallScript projects: The OnAbort event handler is called when a setup is aborted via the abort keyword.<br><br>In InstallScript MSI projects: Responds to the Abort event generated by InstallScript's abort command.                                                                                                                                                              |
| <b>OnAdminInstallUIAfter</b>  | InstallScript MSI                   | Responds to the Admin Install UI After event.                                                                                                                                                                                                                                                                                                                                            |
| <b>OnAdminInstallUIBefore</b> | InstallScript MSI                   | Responds to the Admin Install UI Before event by displaying dialogs that gather information from the end user for an administrative installation of an application.                                                                                                                                                                                                                      |
| <b>OnAdminPatchUIAfter</b>    | InstallScript MSI                   | Called after the file transfer of an administrative patch.                                                                                                                                                                                                                                                                                                                               |
| <b>OnAdminPatchUIBefore</b>   | InstallScript MSI                   | Called before the file transfer of an administrative patch.                                                                                                                                                                                                                                                                                                                              |
| <b>OnAdvertisementAfter</b>   | InstallScript MSI                   | Responds to the Advertisement After event.                                                                                                                                                                                                                                                                                                                                               |
| <b>OnAdvertisementBefore</b>  | InstallScript MSI                   | Responds to the Advertisement After Before event.                                                                                                                                                                                                                                                                                                                                        |
| <b>OnCanceling</b>            | InstallScript,<br>InstallScript MSI | InstallScript projects: The OnCanceling event is sent when the installation is cancelled, usually as result of the end user clicking the Cancel button of a dialog or pressing the Esc key. Calling Do(EXIT) will also trigger this event.<br><br>In InstallScript MSI projects: Responds to the Cancel event generated when the end user clicks the Cancel button in a built-in dialog. |
| <b>OnComponentError</b>       | InstallScript,<br>InstallScript MSI | In InstallScript projects: The OnComponentError event is called by the framework when the call to FeatureTransferData or FeatureMoveData returns an error.<br><br>In InstallScript MSI projects: Responds to general file-transfer errors.                                                                                                                                               |
| <b>OnDIFxLogCallback</b>      | InstallScript                       | Called when a DIFx-related event occurs that is logged by the built-in DIFx callback functionality.                                                                                                                                                                                                                                                                                      |
| <b>OnError</b>                | InstallScript MSI                   | This event is called when MSI sends an INSTALLMESSAGE_ERROR message.                                                                                                                                                                                                                                                                                                                     |
| <b>OnException</b>            | InstallScript MSI                   | Responds to exceptions generated by a procedural script.                                                                                                                                                                                                                                                                                                                                 |

**Table 18** • Miscellaneous Event Handlers (cont.)

| Event Handler                           | Project Type                        | Description                                                                                                                                                                                                                                                                         |
|-----------------------------------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnFileError</b>                      | InstallScript                       | The OnFileError event is sent when an unknown error occurs during the installation or uninstallation of a file.                                                                                                                                                                     |
| <b>OnFileLocked</b>                     | InstallScript                       | The OnFileLocked event is called when a file that is in use by another application needs to be installed or uninstalled unless the files are in a file group which is potentially marked as locked or shared. In that case, the file will be installed or uninstalled after reboot. |
| <b>OnFileReadOnly</b>                   | InstallScript                       | The OnFileReadOnly event is called when a read-only file needs to be installed or uninstalled.                                                                                                                                                                                      |
| <b>OnFilesInUse</b>                     | InstallScript MSI                   | <p>The OnFilesInUse event handler is called in when the Windows Installer sends an INSTALLMESSAGE_FILESinUSE message to the installation.</p> <p>By default, the OnFilesInUse event handler displays the <b>SdFilesInUse</b> dialog.</p>                                            |
| <b>OnHelp</b>                           | InstallScript,<br>InstallScript MSI | <p>In InstallScript projects: The OnHelp event is called when the end user presses F1 or Do(HELP) is called.</p> <p>In InstallScript MSI projects: Responds to the Help event generated when the end user presses the F1 key.</p>                                                   |
| <b>OnInternetError</b>                  | InstallScript                       | The OnInternetError is called when an error occurs while installing a file from the Internet.                                                                                                                                                                                       |
| <b>OnLaunchAppAndWaitCall<br/>back</b>  | InstallScript,<br>InstallScript MSI | The OnLaunchAppAndWaitCallback is called while the installation is waiting for an application to launch if LAAW_OPTION_USE_CALLBACK was specified when calling the LaunchAppAndWait function.                                                                                       |
| <b>OnLogonUserSetMsiPrope<br/>rties</b> | InstallScript MSI                   | The OnLogonUserSetMsiProperties event handler sets the Windows Installer properties for the logon user support that is described for InstallScript MSI projects in Adding the Ability to Create or Set an Existing User Account.                                                    |
| <b>OnMD5Error</b>                       | InstallScript                       | The OnMD5Error event is called when the MD5 signature of a file being installed does not match the MD5 value stored in the InstallShield CAB file. (The MD5 is calculated when the media is built.)                                                                                 |
| <b>OnMsiSilentInstall</b>               | InstallScript MSI                   | Responds to the MSI Silent Install event generated when a user runs an InstallScript MSI project's .msi package in silent mode.                                                                                                                                                     |

**Table 18** • Miscellaneous Event Handlers (cont.)

| Event Handler               | Project Type                                                                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnNextDisk</b>           | InstallScript                                                                                                                                                             | The OnNextDisk event is called during file transfer when the setup cannot find a data file that is needed. An example of this occurrence is during a multiple floppy or CD install when the next disk is needed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OnOutOfDiskSpace</b>     | InstallScript MSI                                                                                                                                                         | Responds to the target system running out of free disk space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>OnRMFilesInUse</b>       | InstallScript MSI                                                                                                                                                         | <p>The OnRMFilesInUse event handler is called when the Restart Manager is enabled and Windows Installer 4.0 sends an INSTALLMESSAGE_RMFILESINUSE message to the installation.</p> <p>By default, the OnRMFilesInUse event handler displays the SdRMFilesInUse dialog.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 18** • Miscellaneous Event Handlers (cont.)

| Event Handler                  | Project Type      | Description                                                                                                                                                    |
|--------------------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnSelfRegistrationError</b> | InstallScript     | The OnSelfRegistrationError event handler is called directly by the framework when a call to Do(SELFREGISTRATIONPROCESS) fails to register files successfully. |
| <b>OnWarning</b>               | InstallScript MSI | Responds to the Warning event generated when the Windows Installer service sends an INSTALLMESSAGE_WARNING message to the installation's user interface.       |

## OnAbort

**Project** • This information applies to the following project types:

- InstallScript
- InstallScript MSI

The OnAbort event handler responds to the Abort event that is generated by the InstallScript abort statement, which uninstalls any changes made to the target system and then exits. In the event handler, you can place any additional cleanup code that you require, such as deleting temporary files created by your installation.

## OnAdminInstallUIAfter

**Project** • This information applies to InstallScript MSI projects.

The OnAdminInstallUIAfter event handler responds to the Admin Install UI After event. It performs tasks that must take place after data transfer for an administrative installation of an application. To perform an administrative installation, the user launches Setup.exe with the /a switch.

Typically, this handler calls **SdFinishEx** to inform the user that the administrative installation is complete.

## OnAdminInstallUIBefore

**Project** • This information applies to InstallScript MSI projects.

The OnAdminInstallUIBefore event handler responds to the Admin Install UI Before event. It performs tasks that must take place before data transfer for an administrative installation of an application. To perform an administrative installation, the user launches Setup.exe with the /a switch.

Typically, this handler calls the **SdWelcome** and **AdminAskPath** functions to welcome the administrative user and prompt for a destination directory.

## OnAdminPatchUIAfter

**Project** ▪ This information applies to InstallScript MSI projects.

The AdminPatchUIAfter event is called after the file transfer of an admin patch setup. By default this event displays UI that informs the end user that the installation has been completed successfully.

## OnAdminPatchUIBefore

**Project** ▪ This information applies to InstallScript MSI projects.

The OnAdminInstallUIBefore event is called before the file transfer in an admin patch setup. By default this event displays UI allowing the end user to specify installation parameters.

## OnAdvertisementAfter

**Project** ▪ This information applies to InstallScript MSI projects.

The OnAdvertisementAfter event handler responds to the Advertisement After event. It performs tasks that must take place after an advertised installation, which occurs when the user runs Setup.exe with the /j argument.

## OnAdvertisementBefore

**Project** ▪ This information applies to InstallScript MSI projects.

The OnAdvertisementBefore event handler responds to the Advertisement Before event. It performs tasks that must take place before an advertised installation, which occurs when the user runs Setup.exe with the /j argument.

## OnCanceling

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The OnCanceling event handler responds to the Cancel event that is generated when the end user clicks the Cancel button in one of the built-in InstallScript dialogs.

```
function OnCanceling( )
begin
```

```

if (YES = AskYesNo(
    "Are you sure you want to cancel the setup?",
    YES))
    then abort;
endif;

end;

```

## OnComponentError

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The OnComponentError event handler responds to the ComponentError event that is generated when the installation encounters a general file-transfer error.

The default OnComponentError implementation uses properties of an ErrorInfo object that is declared in OnComponentError and assigned a value by the following statement:

```
set ErrorInfo = ComponentErrorInfo( );
```

**Table 19** ▪ OnComponentError Parameters

| Property                               | Description                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ErrorInfo.Feature</b>               | An object whose properties provide information about the feature that was being transferred when the error occurred. If the error is not associated with a particular feature, or the feature cannot be identified, this property is not set; test for this case by checking the value of <code>IsObject(ErrorInfo.Feature)</code> . |
| <b>ErrorInfo.Feature.Description</b>   | A string describing the file transfer error. This string may be null ( <code>""</code> ).                                                                                                                                                                                                                                            |
| <b>ErrorInfo.Feature.DisplayName</b>   | The display name of the feature that was being transferred when the error occurred. If you did not specify a display name for this feature, this string is null ( <code>""</code> ).                                                                                                                                                 |
| <b>ErrorInfo.Feature.Name</b>          | The name of the feature that was being transferred when the error occurred.                                                                                                                                                                                                                                                          |
| <b>ErrorInfo.FileError.Description</b> | A string-formatted description of <code>ErrorInfo.LastError</code> .                                                                                                                                                                                                                                                                 |
| <b>ErrorInfo.FileError.File</b>        | For a file-related error: The path and name of the file that encountered an error while the installation attempted to transfer it.                                                                                                                                                                                                   |
| <b>ErrorInfo.FileGroup</b>             | The name of the component that is being transferred when the error occurs.                                                                                                                                                                                                                                                           |
| <b>ErrorInfo.LastError</b>             | The numeric code for the file-transfer error.                                                                                                                                                                                                                                                                                        |

## OnDIFxLogCallback

**Project** ▪ This information applies to *InstallScript* projects.

The `OnDIFxLogCallback` event handler is called when a DIFx-related event occurs that is logged by the built-in DIFx callback functionality. See the Windows documentation on `DIFXAPISetLogCallback` for more information.

**Note** ▪ This event is not supported for 64-bit drivers and is not called as a result of installing a 64-bit driver.

### Syntax

```
OnDIFxLogCallback ( byval number nEventType, byval number nError, byval string szDescription );
```

## Parameters

**Table 20** ▪ OnDIFxLogCallback Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nEventType</b>    | <p>The event type as documented in the DIFxAPI. The following values are available:</p> <ul style="list-style-type: none"> <li>• <b>DIFXAPI_SUCCESS</b>—A success event that logs a message that indicates an operation succeeded.</li> <li>• <b>DIFXAPI_INFO</b>—An information event that logs a message that describes the context or progress of an operation.</li> <li>• <b>DIFXAPI_WARNING</b>—A warning event that logs a message about a possible problem that is not a fatal error.</li> <li>• <b>DIFXAPI_ERROR</b>—An error event that logs a message about a fatal error.</li> </ul> |
| <b>nError</b>        | Specifies a Win32 error code that is associated with an event if one exists; otherwise, zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szDescription</b> | A string that describes the event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Return Values

None.

## OnError

**Project** ▪ This information applies to InstallScript MSI projects.

This event is called when Windows Installer sends an INSTALLMESSAGE\_ERROR message.

## OnException

**Project** ▪ This information applies to InstallScript MSI projects.

The OnException event handler responds to exceptions that are generated by a procedural script (one that uses an explicit program...endprogram block). The default implementation displays the error number, source, and description that are stored in the [Err Object](#).

Note that OnException is not called in an event-based script. For an event-based script, you must implement your own try...catch...endcatch blocks to catch exceptions.

## OnFileError

**Project** ▪ This information applies to InstallScript projects.

The OnFileError event handler responds to the FileError event that is generated when the setup encounters a file error that does not generate any other file error event (for example, FileLocked or FileReadOnly). When creating an InstallShield object, note that this event is not triggered in an object.

This event handler is called (when appropriate) in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

### Syntax

```
OnFileError ( szFilename, nError );
```

### Parameters

**Table 21** ▪ OnFileError Parameters

| Parameter         | Description                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified file name of the file for which the error occurred.              |
| <b>nError</b>     | Specifies the value returned by the Windows API function GetLastError when the error occurred. |

### Return Values

**Table 22** ▪ OnFileError Return Values

| Return Value      | Description                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ERR_IGNORE</b> | Returned to the setup by the OnFileError event handler to request that the setup ignore the failure to install or uninstall the file specified in OnFileError's first argument and continue without performing the operation. |
| <b>ERR_RETRY</b>  | Returned to the setup by the OnFileError event handler to request that the setup attempt again to install or uninstall the file specified in OnFileError's first argument.                                                    |
| <b>ERR_ABORT</b>  | Returned to the setup by the OnFileError event handler to request that the setup be aborted.                                                                                                                                  |

## OnFileLocked

**Project** ▪ This information applies to InstallScript projects.

The OnFileLocked event handler responds to the FileLocked event that is generated when the setup encounters a locked (in use) file that must be deleted or overwritten. When creating an InstallShield object, note that this event is not triggered in an object.

This event handler is not called for files that are in components whose Potentially Locked property is set to Yes. In this case the file operation is automatically performed after reboot.

This event handler is called (when appropriate) in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

## Syntax

```
OnFileLocked ( szFilename );
```

## Parameters

**Table 23** • OnFileLocked Parameters

| Parameter         | Description                                                 |
|-------------------|-------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified file name of the locked file. |

## Return Values

**Table 24** • OnFileLocked Return Values

| Return Value                    | Description                                                                                                                                                                                                               |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ERR_IGNORE</b>               | Returned to the setup by the OnFileLocked event handler to request that the setup ignore the failure to install or uninstall the file specified in OnFileLocked's argument and continue without performing the operation. |
| <b>ERR_RETRY</b>                | Returned to the setup by the OnFileLocked event handler to request that the setup attempt again to install or uninstall the file specified in OnFileLocked's argument.                                                    |
| <b>ERR_ABORT</b>                | Returned to the setup by the OnFileLocked event handler to request that the setup be aborted.                                                                                                                             |
| <b>ERR_PERFORM_AFTER_REBOOT</b> | Returned to the setup by the OnFileLocked event handler to request that the setup perform the operation on the file after the target system is rebooted.                                                                  |

## OnFileReadOnly

**Project** • This information applies to InstallScript projects.

The OnFileReadOnly event handler responds to the ReadOnly event that is generated when a file that must be deleted or overwritten is set to Read Only. When creating an InstallShield object, note that this event is not triggered in an object.

This event handler is called (when appropriate) in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

## Syntax

```
OnFileReadOnly ( szFilename );
```

## Parameters

**Table 25** ▪ OnFileReadOnly Parameters

| Parameter         | Description                                                    |
|-------------------|----------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified file name of the read-only file. |

## Return Values

**Table 26** ▪ OnFileReadyOnly Return Values

| Return Value   | Description                                                                                                                      |
|----------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>ERR_YES</b> | Returned to the setup by the OnRemovingSharedFile event handler to request that the setup perform the operation on the file.     |
| <b>ERR_NO</b>  | Returned to the setup by the OnRemovingSharedFile event handler to request that the setup not perform the operation on the file. |

# OnFilesInUse

**Project** ▪ This information applies to InstallScript MSI projects.

The OnFilesInUse event handler is called in an InstallScript MSI installation when the Windows Installer sends an INSTALLMESSAGE\_FILESINUSE message to the installation.

The szMessage parameter contains the string that the Windows Installer provides. This parameter indicates the files that are in use. The **SdFilesInUse** function parses this string appropriately.

By default, the OnFilesInUse event handler displays the **SdFilesInUse** dialog. The event handler returns the value that the dialog returns, and the value is then passed back to the Windows Installer to indicate how the message was handled and what action the Windows Installer should take.

## Syntax

```
OnFilesInUse (szMessage);
```

## Parameters

**Table 27** ▪ OnFilesInUse Parameters

| Parameter        | Description                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMessage</b> | String provided by the Windows Installer indicating the files that are in use. The <b>SdFilesInUse</b> function parses this string. |

## Return Values

**Table 28** ▪ OnFilesInUse Return Values

| Return Value    | Description                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IDCANCEL</b> | Indicates that the installation should be cancelled.                                                                                                 |
| <b>IDRETRY</b>  | Indicates that the Windows Installer should recheck for in-use files and send the <code>INSTALLMESSAGE_FILESINUSE</code> message if it still needed. |
| <b>IDIGNORE</b> | Indicates that the Windows Installer should ignore the fact that the files are in use and should continue the installation.                          |

## OnHelp

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The OnHelp event handler responds to the Help event generated when the end user presses the F1 key.

```
function OnHelp( )
begin
    /* Assumes that MySetupHelp.chm is located
       in the Support Files/Billboards view. */
    LaunchAppAndWait( WINDIR ^ "Hh.exe",
                     SUPPORTDIR ^ "MySetupHelp.chm",
                     NOWAIT );
end;
```

## OnInternetError

**Project** ▪ This information applies to *InstallScript* projects.

The OnInternetError event handler responds to the FileError event that is generated when the setup encounters a file error that does not generate any other file error event (for example, FileLocked or FileReadOnly). When creating an InstallShield object, note that this event is not triggered in an object.

This event handler is called (when appropriate) in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

## Syntax

```
OnInternetError ( hInternet, szFilename, nError );
```

## Parameters

**Table 29** ▪ OnInternetError Parameters

| Parameter         | Description                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------|
| <b>hInternet</b>  | Internal handle—ignore.                                                                        |
| <b>szFilename</b> | Specifies the fully qualified file name of the file for which the error occurred.              |
| <b>nError</b>     | Specifies the value returned by the Windows API function GetLastError when the error occurred. |

## Return Values

**Table 30** ▪ OnInternetError Return Values

| Return Value      | Description                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ERR_IGNORE</b> | Returned to the setup by the OnInternetError event handler to request that the setup ignore the failure to install or uninstall the file specified in OnInternetError's second argument and continue without performing the operation. |
| <b>ERR_RETRY</b>  | Returned to the setup by the OnInternetError event handler to request that the setup attempt again to install or uninstall the file specified in OnInternetError's second argument.                                                    |
| <b>ERR_ABORT</b>  | Returned to the setup by the OnInternetError event handler to request that the setup be aborted.                                                                                                                                       |

## OnLaunchAppAndWaitCallback

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The OnLaunchAppAndWaitCallback event handler is called while the installation is waiting for an application to launch if LAAW\_OPTION\_USE\_CALLBACK was specified when calling the **LaunchApplication** function. The event is called in the intervals determined by the amount of time specified in the LAAW\_PARAMETERS.nCallbackInterval parameter.

If the installation contains multiple **LaunchApplication** calls in which LAAW\_OPTION\_USE\_CALLBACK was specified, the same event is called during each wait. In this case, use the LAAW\_PARAMETERS.szCommandLineResult parameter to determine which call is currently being executed. You can return LAAW\_CALLBACK\_RETURN\_CONTINUE\_TO\_WAIT to continue waiting or LAAW\_CALLBACK\_RETURN\_END\_WAIT to end the wait immediately.

```
function number OnLaunchAppAndWaitCallback( )
begin
    return LAAW_CALLBACK_RETURN_CONTINUE_TO_WAIT;
end;
```

---

**Note** ▪ This event handler appears in installations and object projects. Any specified override for this event applies on to the script in which it is overwritten. An override in the main installation script does not affect contained objects and an override in an object project has no effect on the main installation script.

## OnLogonUserSetMsiProperties

---

**Project** ▪ This information applies to InstallScript MSI projects.

The OnLogonUserSetMsiProperties event handler sets the Windows Installer properties for the logon user support that is described for InstallScript MSI projects in Adding the Ability to Create or Set an Existing User Account. Specifically, OnLogonUserSetMsiProperties sets the following

- The Windows Installer property IS\_NET\_API\_LOGON\_USERNAME is set to the InstallScript variable IFX\_NETAPI\_USER\_ACCOUNT
- The Windows Installer property IS\_NET\_API\_LOGON\_PASSWORD is set to the InstallScript variable IFX\_NETAPI\_PASSWORD
- The Windows Installer property IS\_NET\_API\_LOGON\_GROUP is set to the InstallScript variable IFX\_NETAPI\_GROUP.

The IFX\_NETAPI\_\* variables are set to the values of the input fields in the **SdLogonUserInformation** and related dialogs.

## OnMD5Error

---

**Project** ▪ This information applies to InstallScript projects.

The OnMD5Error event handler responds to the MD5Error event that is generated during MD5 checking when the setup extracts a file whose MD5 hash value does not correspond to the value stored in the setup header file. When creating an InstallShield object, note that this event is not triggered in an object.

This event handler is called (when appropriate) in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

**Tip** ▪ MD5 checking can detect corrupted files, which is useful during Internet setups; not doing MD5 checking can make file transfer proceed faster. You can enable or disable MD5 checking with the Advanced button in the Release Wizard's General Options panel, or with the Setup.ini file's [Startup] section's CheckMD5 key.

## Syntax

```
OnMD5Error ( szFilename );
```

## Parameters

**Table 31** ▪ OnMD5Error Parameters

| Parameter         | Description                                                                       |
|-------------------|-----------------------------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified file name of the file that generated the MD5 error. |

## Return Values

**Table 32** ▪ OnMD5Error Return Values

| Return Value      | Description                                                                                                                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ERR_IGNORE</b> | Returned to the setup by the OnMD5Error event handler to request that the setup ignore the failure to install or uninstall the file specified in OnMD5Error's argument and continue without performing the operation. |
| <b>ERR_RETRY</b>  | Returned to the setup by the OnMD5Error event handler to request that the setup attempt again to install or uninstall the file specified in OnMD5Error's argument.                                                    |
| <b>ERR_ABORT</b>  | Returned to the setup by the OnMD5Error event handler to request that the setup be aborted.                                                                                                                           |

## Additional Information

An MD5Error event will be generated at run time if, after running the media builder, you replace an uncompressed file in a disk image folder. You can modify the default OnMD5Error code to automatically handle this MD5Error event rather than display a dialog. For example, to automatically ignore the MD5Error event for the file ReplacedAfterBuild.txt, which is installed to TARGETDIR, add the following lines at the beginning of the OnMD5Error code:

```
if szFilename = TARGETDIR ^ "ReplacedAfterBuild.txt" then
    return ERR_IGNORE;
endif;
```

## OnMsiSilentInstall

**Project** ▪ This information applies to InstallScript MSI projects.

An installation program created by an InstallScript MSI project requires the end user to run Setup.exe. The OnMsiSilentInstall event handler responds to the end user attempting to run an InstallScript MSI project's .msi database in silent mode with the /q option to MsiExec.exe. The default implementation is to display an error message and then abort the installation.

## OnNextDisk

**Project** ▪ This information applies to InstallScript projects.

Because the Windows Installer handles disk prompts, this event is not supported for InstallScript MSI projects.

The OnNextDisk event handler responds to the NextDisk event that occurs in a multi-disk setup when the next disk in the sequence is required to continue the setup.

### Return Values

**Table 33** ▪ OnNextDisk Return Values

| Return Value     | Description                                                                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ERR_RETRY</b> | Returned to the setup by the OnNextDisk event handler to request that the setup search again for the file specified in OnNextDisk's first argument. |
| <b>ERR_ABORT</b> | Returned to the setup by the OnNextDisk event handler to request that the setup be aborted.                                                         |

## OnOutOfDiskSpace

**Project** ▪ This information applies to InstallScript MSI projects.

The OnOutOfDiskSpace event handler responds to the Out Of Disk Space event. The default implementation of OnOutOfDiskSpace displays the [SdDiskSpace2](#) dialog, and then aborts the installation.

## OnPatchUIAfter

**Project** ▪ This information applies to InstallScript MSI projects.

The OnPatchUIAfter event handler is called after data transfer for a patch installation. The default implementation of OnPatchUIAfter calls the [SdFinishEx](#) function.

## OnPatchUIBefore

**Project** - This information applies to InstallScript MSI projects.

The OnPatchUIBefore event handler is called when the user launches a patch installation. The default implementation of OnPatchUIBefore calls the [SdPatchWelcome](#) dialog function.

## OnRebooted

**Project** - This information applies to the following project types:

- InstallScript
- InstallScript MSI—if the InstallScript user interface (UI) style is the traditional style (which uses the InstallScript engine as an external UI handler)

*This information does not apply to InstallScript MSI projects in which the InstallScript UI style is the new style (which uses the InstallScript engine as an embedded UI handler). To learn more, see [Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations](#).*

The OnRebooted event handler responds to the Rebooted event that the installation generates when it restarts after the target system is rebooted. When the installation restarts after reboot, OnRebooted is the only event handler it calls.

## OnRemovingSharedFile

**Project** - This information applies to InstallScript projects.

The OnRemovingSharedFile event handler responds to the RemovingSharedFile event that occurs during uninstallation when a file that might be shared with other applications is about to be removed. When creating an InstallShield object, note that this event is not triggered in an object.

This event handler is called (when appropriate) in any setup, including a setup that uses a procedural script (a script with a program...endprogram block).

### Syntax

```
OnRemovingSharedFile ( szFilename );
```

## Parameters

**Table 34** ▪ OnRemovingSharedFile Parameters

| Parameter         | Description                                                 |
|-------------------|-------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified file name of the shared file. |

## Return Values

**Table 35** ▪ OnRemovingSharedFile Return Values

| Return Value   | Description                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------|
| <b>ERR_YES</b> | Returned to the setup by the OnRemovingSharedFile event handler to request that the setup remove the file.     |
| <b>ERR_NO</b>  | Returned to the setup by the OnRemovingSharedFile event handler to request that the setup not remove the file. |

## OnResumeUIAfter

**Project** ▪ This information applies to InstallScript MSI projects.

The OnResumeUIAfter event handler responds to the Resume UI After event. It performs tasks that must take place after an application's reinstallation or minor upgrade.

The OnResumeUIAfter and OnResumeUIBefore event handlers are called only when all of the following conditions apply:

- The application is already installed on the target machine.
- A patch is *not* being run.
- One of the following properties is set at the command line or in the CmdLine property of Setup.ini:
  - ADDDEFAULT
  - ADDLOCAL
  - ADDSOURCE
  - ADVERTISE
  - COMPADDLOCAL
  - COMPADDSOURCE
  - FILEADDDEFAULT
  - FILEADDLOCAL
  - FILEADDSOURCE

- REINSTALL
- REMOVE

## OnResumeUIBefore

**Project** ▪ This information applies to InstallScript MSI projects.

The OnResumeUIBefore event handler responds to the Resume UI Before event. It performs tasks that must take place before an application's reinstallation or minor upgrade.

The OnResumeUIBefore and OnResumeUIAfter event handlers are called only when all of the following conditions apply:

- The application is already installed on the target machine.
- A patch is *not* being run.
- One of the following properties is set at the command line or in the CmdLine property of Setup.ini:
  - ADDDEFAULT
  - ADDLOCAL
  - ADDSOURCE
  - ADVERTISE
  - COMPADDLOCAL
  - COMPADDSOURCE
  - FILEADDDEFAULT
  - FILEADDLOCAL
  - FILEADDSOURCE
  - REINSTALL
  - REMOVE

## OnRMFilesInUse

**Project** ▪ This information applies to InstallScript MSI projects.

The OnRMFilesInUse event handler is called in an InstallScript MSI installation when the Restart Manager is enabled and Windows Installer 4.0 sends an INSTALLMESSAGE\_RMFILESINUSE message to the installation.

Note that the INSTALLMESSAGE\_RMFILESINUSE message is not sent if the Restart Manager is unavailable or disabled. For more information, see [MSIRESTARTMANAGERCONTROL Property](#) in the Windows Installer Help Library.

If the Restart Manager is unavailable or disabled, or if the target system has Windows Installer 3.x or earlier, Windows Installer sends an `INSTALLMESSAGE_FILESINUSE` message to the installation.

By default, the `OnRMFilesInUse` event handler displays the **SdRMFilesInUse** dialog. The event handler returns the value that the dialog returns, and the value is then passed back to the Windows Installer to indicate how the message was handled and what action the Windows Installer should take.

## Syntax

```
OnRMFilesInUse (szMessage);
```

## Parameters

**Table 36** ▪ OnRMFilesInUse Parameters

| Parameter        | Description                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMessage</b> | String provided by the Windows Installer indicating the files that are in use. The <b>SdRMFilesInUse</b> function parses this string. |

## Return Values

**Table 37** ▪ OnRMFilesInUse Return Values

| Return Value    | Description                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IDCANCEL</b> | Indicates that the installation should be cancelled.                                                                                                                                                                                                                                                                                                                   |
| <b>IDRETRY</b>  | Indicates that the Windows Installer should recheck for in-use files and send the <code>INSTALLMESSAGE_RMFILESINUSE</code> message if it still needed.<br><br><br><b>Note</b> ▪ Unlike the <i>SdFilesInUse</i> dialog, the <i>SdRMFilesInUse</i> dialog does not return this value. |
| <b>IDIGNORE</b> | Indicates that the Windows Installer should ignore the fact that the files are in use and should continue the installation.                                                                                                                                                                                                                                            |
| <b>IDOK</b>     | Indicates that the Windows Installer should use the Restart Manager to attempt to shut down running applications that are locking files. For more information, see <code>INSTALLMESSAGE_RMFILESINUSE</code> in the Windows Installer Help Library.                                                                                                                     |

## OnSelfRegistrationError

**Project** ▪ This information applies to *InstallScript* projects.

The OnSelfRegistrationError event handler is called directly by the framework when a call to Do(SELFREGISTRATIONPROCESS) fails to register files successfully.

Syntax

```
OnSelfRegistrationError ( );
```

Parameters

None.

Return Values

None.

Additional Information

The default OnSelfRegistrationError code uses the following properties of the global FileRegistrar object:

Table 38 • Global FileRegistrar Object Properties

| Property                            | Description                                                                                                                                                  |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FileRegistrar.Errors.Count          | The number of self-registering files that were not registered.                                                                                               |
| FileRegistrar.Errors(i)             | An object whose properties provide information about the <i>i</i> -th unregistered file. ( <i>i</i> runs from 1 to the value of FileRegistrar.Errors.Count.) |
| FileRegistrar.Errors(i).File        | The name of the <i>i</i> -th unregistered file.                                                                                                              |
| FileRegistrar.Errors(i).Description | A string describing the error that occurred when the setup attempted to register the <i>i</i> -th unregistered file. This string may be null ("").           |
| FileRegistrar.Errors(i).LastError   | The numeric code for the error that occurred when the setup attempted to register the <i>i</i> -th unregistered file.                                        |

OnWarning

**Project** • This information applies to InstallScript MSI projects.

The OnWarning event handler responds to the Warning event, which is raised when the Windows Installer service sends a INSTALLMESSAGE\_WARNING message.

# Advanced Event Handlers

Advanced event handlers are triggered under special circumstances.

**Table 39** ▪ Advanced Event Handlers

| Event Handler        | Project Type                        | Description                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OnShowUI</b>      | InstallScript                       | Called directly by the installation engine to initiate the user interface and file transfer.                                                                                                                                                                                                                                                                  |
| <b>OnSuiteShowUI</b> | InstallScript                       | When an Advanced UI or Suite/Advanced UI installation launches an InstallScript package, the OnSuiteShowUI event is called instead of the OnShowUI event. By default, the OnSuiteShowUI event initializes any feature states that are passed from an Advanced UI or Suite/Advanced UI installation to the InstallScript package, and it starts file transfer. |
| <b>OnUninstall</b>   | InstallScript,<br>InstallScript MSI | The OnUninstall event handler is called when the installation is run with the /uninst parameter. This is the only event that is called when the /uninst parameter is used. The default code for the OnUninstall event uninstalls a previously installed product.                                                                                              |

## OnShowUI

The OnShowUI event drives the UI sequence and file transfer of the installation.

The OnShowUI event is called directly by the framework to initiate the UI sequence and file transfer of the installation. By default, this event displays UI that informs the end user that maintenance has been completed successfully.

**Note** ▪ This event is not called automatically in a program...endprogram style installation.

### Syntax

```
OnShowUI ( );
```

### Parameters

None.

### Return Values

None.

## Additional Information

You can easily convert a procedural script to an event-based script by performing the following steps. If you do this, neither the user interface event handlers (OnFirstUIBefore, OnMaintUIBefore, OnUpdateUIBefore, OnFirstUIAfter, OnMaintUIAfter, and OnUpdateUIAfter) nor OnMoveData are called; but all other feature event handlers are called as appropriate.

### Task

#### **To convert a procedure script to an event-based script:**

1. Open your project in InstallShield; when you are prompted to convert it, click Yes.
2. Open the script and change the following line:

```
program
```

to this:

```
function OnShowUI
begin
```

3. Also change the following line:

```
endprogram
```

to this:

```
end
```

4. If you are planning to display any custom objects that include a user interface (objects provided with InstallShield do not), add a call to [ShowObjWizardPages](#) to your dialog sequence at the location where you want any object UI to be shown:

```
ShowObjWizardPages( nResult );
```

This function can be called before or after file transfer; the appropriate object event is called based on whether or not file transfer has occurred and on the value of the MAINTENANCE system variable.

5. Make the changes needed to compile the script in InstallShield.

You can also customize the OnBegin and OnEnd events if you wish.

## Why This Works

In InstallScript, most installation events are driven by the main UI event, OnShowUI. When you replace the default code in this event with the code in your program...endprogram block, you are basically providing a custom UI sequence. Note that since OnShowUI is called when the installation is run, your installation behaves just like it did when it was a program...endprogram script.

## Launching an InstallScript Package in an Advanced UI or Suite/Advanced UI Installation

Note that when an Advanced UI or Suite/Advanced UI installation launches an InstallScript package, the [OnSuiteShowUI event](#) is called instead of the OnShowUI event.

## OnSuiteShowUI

**Project** ▪ This information applies to InstallScript projects.

When an Advanced UI or Suite/Advanced UI installation launches an InstallScript package, the OnSuiteShowUI event is called instead of the **OnShowUI event**. By default, the OnSuiteShowUI event initializes any feature states that are passed from an Advanced UI or Suite/Advanced UI installation to the InstallScript package, and it starts file transfer. The OnSuiteShowUI event does not typically show any user interface, since the Advanced UI or Suite/Advanced UI installation's setup launcher typically handles the user interface for the entire Advanced UI or Suite/Advanced UI installation.

Depending on the installation state (first-time installation, maintenance, or update), OnSuiteShowUI ignores the UI events such as OnFirstUIBefore and OnFirstUIAfter and instead calls the following events:

- **First-time installation**—OnSuiteInstallBefore, OnSuiteInstallAfter
- **Maintenance**—OnSuiteMaintBefore, OnSuiteMaintAfter
- **Update**—OnSuiteUpdateBefore, OnSuiteUpdateAfter

All other events and event call sequencing in an InstallScript package that is launched from an Advanced UI or Suite/Advanced UI installation remain the same as in an InstallScript installation that is launched separate from an Advanced UI or Suite/Advanced UI installation, or that is launched as an executable package from an Advanced UI or Suite/Advanced UI installation.

**Note** ▪ This event is not called automatically in a program...endprogram style installation.

## OnUninstall

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The OnUninstall event is called when the installation is run with the /uninst parameter. This is the only event that is called when the /uninst parameter is used. The default code for the OnUninstall event uninstalls a previously installed product.

# Functions

A function is a named set of instructions that operate together to perform a specific task.

## Function Characteristics

Every function has the following characteristics:

- A function is named. Each function has a unique name. When you call the function by name, you know which set of instructions will run, and you can be sure of consistent results. You can also call a function from within another function.
- A function is independent. In most cases, any function can perform its instructions without interfering with other parts of the program.
- A function performs a certain task. A task is any single job that the script must perform, such as displaying a bitmap, compressing a file, or creating a folder.
- A function can return a value to the script. When the script executes, it performs the instructions of the function. Based on the result of the instructions, a function can return information to the script.

## Function Types

InstallShield allows you to use three types of functions in your setup script:

**Table 1** • Function Types

| Function Type                 | Description                                                     |
|-------------------------------|-----------------------------------------------------------------|
| <b>Built-in functions</b>     | Functions supplied by InstallShield or included for Sd dialogs. |
| <b>User-defined functions</b> | Functions that you create.                                      |
| <b>DLL-called functions</b>   | Functions that you can call in a DLL.                           |

**Note** • Like the C programming language, InstallScript does not support nested function blocks.

## Using Built-In Functions

InstallShield has several hundred built-in functions that you can use in your setup scripts to create program groups and items, manipulate folders, work with lists, monitor the status of the setup, create dialogs, manipulate files, and much more. Because the InstallShield Script Compiler already recognizes these function names, you do not have to declare them before you can use them.

## Learning About Function Names and Formats

In order call a built-in function, you must know both its name and its format.

To find a function that will fit your requirements, review [Built-In Functions by Category](#), which describes each of the major categories of available functions. Click a category link to view a list of functions and descriptions that pertain to that category.

All of the built-in functions are listed alphabetically in the Built-in Functions sections. To display a complete description of any function in that list, click its name. The help topic for that function provides the function's format.

For example, AskYesNo is a built-in function that displays a query in a dialog and then waits for the end user to respond by clicking a button, either Yes or No. AskYesNo has the following format:

```
AskYesNo (szQuestion, nDefault);
```

The format shows the correct spelling of the function name, which is followed by the function's parameter list, enclosed in parentheses. In the help topic for a built-in function, each parameter is expressed in Hungarian notation, which indicates the type of data that must be passed in that position. AskYesNo requires two parameters: the first parameter is a string; the second is a number.

---

**Note** ▪ Like C, InstallScript is case sensitive. Be sure to pay close attention to the capitalization of letters in the built-in function names.

## Using Built-In Functions in Your Script

To use a built-in function in your script, pass the required number of parameters, and make sure that the data you pass in each parameter is the type indicated for that position. If you pass the incorrect number of parameters, or if you pass the wrong type of data in any parameter positions, the script will not compile.

The specific documentation for each built-in function provides a description of its parameters. For AskYesNo, szQuestion is the question to be displayed in the dialog and nDefault indicates which button to preselect—Yes or No. One of two predefined constants can be passed in nDefault: YES or NO.

Consider a dialog in which the Yes button is preselected. To display this dialog, call AskYesNo as shown below:

```
AskYesNo ("Installation Complete. Would you like to view the ReadMe file now?", YES);
```

---

**Note** ▪ String literals passed as parameters must be enclosed in single or double quotation marks, for example: "Please wait while files are transferred", or 'This is a string', or "C:\\Myfolder\\Myfile.ext".

## Troubleshooting

Note the following:

- InstallScript functions do not allow you to pass an assignment statement as a parameter. In addition, you cannot use the && or || operators within an argument to a function.
- An autosized string variable that is passed by reference to a function will not be autosized within the called function. If the function attempts to assign a value whose length is greater than the current size of that parameter, run-time error 401 occurs. To avoid this error, declare strings with a specific size when they are to be passed by reference to a function.

# Built-In Functions by Category

The following categories of functions are available in the InstallScript language.

**Table 2** • Built-In Functions by Category

| Function Category                     | Description                                                                                                                                                                                                                  |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Batch File Functions</b>           | Work with batch files.                                                                                                                                                                                                       |
| <b>Component Functions</b>            | In InstallShield, feature functions replace the component functions that were used in InstallShield Professional.                                                                                                            |
| <b>Configuration File Functions</b>   | Modify the default system configuration file.                                                                                                                                                                                |
| <b>Device Driver Functions</b>        | Install and uninstall device drivers using DIFx.                                                                                                                                                                             |
| <b>Dialog Functions</b>               | Create InstallScript dialogs and message boxes.                                                                                                                                                                              |
| <b>Dialog Customization Functions</b> | Customize InstallScript dialogs, and modify the text, controls, and behavior of InstallScript dialogs.                                                                                                                       |
| <b>Extensibility Functions</b>        | Call functions in dynamic-link libraries, call Windows APIs, launch another application or setup script, and load or unload a .dll file into memory.                                                                         |
| <b>Feature Functions</b>              | Control file media. Also create and process script-created feature sets.                                                                                                                                                     |
| <b>File and Folder Functions</b>      | Work with text files, binary files, and folders.                                                                                                                                                                             |
| <b>Information Functions</b>          | Enables you to use FlexNet Connect to notify end users about updates that are available for your product.                                                                                                                    |
| <b>Information Functions</b>          | Provide data about resources that are available in the operating environment: disk space, memory, and operating mode.                                                                                                        |
| <b>Initialization File Functions</b>  | Obtain information from and copy information to the initialization and profile files.                                                                                                                                        |
| <b>List Processing Functions</b>      | Implement lists in a setup script.                                                                                                                                                                                           |
| <b>Log File Functions</b>             | Obtain information from and copy information to the log file's custom logging section.                                                                                                                                       |
| <b>Long File Name Functions</b>       | Create long file names from short file names, convert short file names to long file names, and place double quotation marks around long file names so that operating systems that handle long file names can recognize them. |
| <b>Miscellaneous Functions</b>        | Serve various purposes, such as low-level hardware interface, feature creation and manipulation, and user output.                                                                                                            |

**Table 2** • Built-In Functions by Category (cont.)

| Function Category                                              | Description                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Object Functions</b>                                        | Initialize objects, as well as obtain and set object status information.                                                                                                                                                                                                                                                     |
| <b>Path Buffer Functions</b>                                   | Work with strings that contain search paths. The path string functions work on a unique temporary string variable known as the path buffer.                                                                                                                                                                                  |
| <b>Registry Functions</b>                                      | Access the registry, read, create and delete registry keys, and establish registry-related parameters for uninstallation.                                                                                                                                                                                                    |
| <b>Shared and Locked File Functions</b>                        | Handle shared or locked files.                                                                                                                                                                                                                                                                                               |
| <b>Shell Functions</b>                                         | Create shortcuts, delete existing shortcuts, and configure shortcuts.                                                                                                                                                                                                                                                        |
| <b>Special Registry-Related Functions</b>                      | Set up the minimum required registry keys and values. The special registry-related functions work only with the per application paths key, the application uninstallation key, or the application information key.                                                                                                           |
| <b>SQL Functions</b>                                           | Perform SQL tasks such as connect to a catalog, create SQL-related dialogs, and obtain SQL run-time errors.                                                                                                                                                                                                                  |
| <b>String Functions</b>                                        | Manipulate string variables and literals. String functions behave similarly to the standard C language functions. The return values also follow the C language convention.                                                                                                                                                   |
| <b>Suite/Advanced UI and Advanced UI Interaction Functions</b> | Interact with an Advanced UI or Suite/Advanced UI installation that contains an InstallScript package, or with a Suite/Advanced UI installation that includes InstallScript actions.                                                                                                                                         |
| <b>Text Substitutions</b>                                      | Associate a string with another string—for example, associating "<MYTEXTSUB>" with "My Text Sub Value"—and of replacing the former string with the latter in other strings—for example, changing "This string demonstrates text substitution <MYTEXTSUB>" to "This string demonstrates text substitution My Text Sub Value". |
| <b>Uninstallation Functions</b>                                | Perform services required for the uninstallation and/or maintenance setup of an installed application.                                                                                                                                                                                                                       |
| <b>User Interface Functions</b>                                | Customize certain error messages and titles of error boxes. Note that several internal error messages that may be encountered during the development of the setup cannot be modified using user interface functions.                                                                                                         |
| <b>Version-Checking Functions</b>                              | Obtain a specific file's version, find a file and get its version, or search for an existing file and try to install a newer version of the file. The functions work with either compressed or uncompressed files.                                                                                                           |

**Table 2** • Built-In Functions by Category (cont.)

| Function Category                  | Description                                                                                                                        |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Windows Installer Functions</b> | Exported by the Windows Installer engine. These functions enable you to query and manipulate properties of a running installation. |

## Batch File Functions

When you work with batch and configuration files, you can treat the files as normal text files, or you can use InstallScript functions designed specifically to modify batch and configuration files.

### Ez and Advanced Batch Functions

There are two classes of InstallScript batch file functions—Ez and advanced. Ez functions are quick and easy to use because they have many preprogrammed features. If you need greater flexibility and control over the changes you need to make to configuration and batch files, use the advanced functions.

### Return Value

InstallShield does not display a message if a batch function fails, but returns a value that is less than zero (< 0). The return value indicates whether the function performed successfully. You can check the return value and display a message based on the result.

## Ez Batch File Functions

Ez batch file functions make modifications to the default batch file. Unless changed by a call to **BatchSetFileName**, the default batch file is the Autoexec.bat file that was executed by the system during the boot sequence. It is important to note that each Ez batch file function opens the default batch file and then saves it automatically after making the specified modification. You do not make calls to open or save when using Ez batch file functions.

**Table 3** • Ez Batch File Functions

| Function                | Description                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EzBatchAddPath</b>   | Modifies the default batch file by adding a directory to the search path in a PATH command or to the value assigned to an environment variable. |
| <b>EzBatchAddString</b> | Adds a line of text to the default batch file.                                                                                                  |
| <b>EzBatchReplace</b>   | Replaces a statement in the default batch file.                                                                                                 |

## Advanced Batch File Functions

Advanced batch file functions differ from Ez batch file functions in that they provide greater flexibility and more control over batch files. Use these functions when you need to make more extensive or complex changes to a batch file.

To edit a batch file with these advanced functions, you must first load the file into memory by calling `BatchFileLoad`. When modifications to the batch file are complete, you must then save the file by calling `BatchFileSave`.

When an InstallScript custom action initializes, InstallShield selects the target system's startup batch file (Autoexec.bat) as the default batch file; unless changed by a call to `BatchSetFileName` this is the file that `BatchFileLoad` reads into memory if no other file name is specified. To determine the fully qualified name of the default batch file, call `BatchGetFileName`.

**Table 4** • Advanced Batch File Functions

| Function                      | Description                                                               |
|-------------------------------|---------------------------------------------------------------------------|
| <code>BatchAdd</code>         | Adds an environment variable to a batch file.                             |
| <code>BatchDeleteEx</code>    | Deletes a line in the batch file.                                         |
| <code>BatchFileLoad</code>    | Loads a batch file into memory for editing with advanced batch functions. |
| <code>BatchFileSave</code>    | Saves a batch file that has been loaded with <code>BatchFileLoad</code> . |
| <code>BatchFind</code>        | Finds items in a batch file.                                              |
| <code>BatchGetFileName</code> | Retrieves the fully qualified file name of the default batch file.        |
| <code>BatchMoveEx</code>      | Moves an item within a batch file.                                        |
| <code>BatchSetFileName</code> | Specifies a batch file to be the default batch file.                      |

## Related Function

**Table 5** • Related Function

| Function                    | Description                                                                                |
|-----------------------------|--------------------------------------------------------------------------------------------|
| <code>SdShowFileMods</code> | Creates a dialog that displays proposed file changes and offers options on how to proceed. |

# Component Functions

Because a Windows Installer-based installation uses features as the highest level of organization in installation projects, and not components, component-related functions are deprecated in InstallShield. All supported component functions now have corresponding feature functions that should be used in your script.

For example, the `ComponentAddItem` function is now `FeatureAddItem`. For more information and a list of available feature-related functions, see [Feature Functions](#)

# Configuration File Functions

Configuration file functions modify the default system configuration file. There are two types of configuration file functions:

- [Ez Config.sys File Functions](#)
- [Advanced Configuration File Functions](#)

## Ez Config.sys File Functions

Ez configuration file functions modify the default system configuration file. Unless changed by a call to [ConfigSetFileName](#), that file is the Config.sys file that was executed by the system during the boot sequence.

**Table 6** • Ez Configuration File Functions

| Function                          | Description                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">EzConfigAddDriver</a> | Adds a device driver statement to the default system configuration file.                |
| <a href="#">EzConfigAddString</a> | Adds a statement or line of text to the default system configuration file.              |
| <a href="#">EzConfigGetValue</a>  | Retrieves the value of a system configuration file parameter, such as FILES or BUFFERS. |
| <a href="#">EzConfigSetValue</a>  | Sets the value of a system configuration file parameter, such as FILES or BUFFERS.      |

**Note** • Each of these functions opens the default system configuration file, performs its assigned task, and then saves the file back to disk. It is not necessary to load and save the configuration file as with the advanced configuration file functions.

## Advanced Configuration File Functions

The advanced configuration file functions provide the advanced developer greater flexibility and more control over system configuration files than do the Ez configuration file functions. To access and edit a system configuration file with these advanced functions, start by calling ConfigFileLoad. When you are finished editing the system configuration file, call ConfigFileSave to save your changes. Note that the functions ConfigGetFileName and ConfigSetFileName can be used with both advanced and Ez configuration file functions.

**Table 7** • Advanced Configuration File Functions

| Function                  | Description                                                                     |
|---------------------------|---------------------------------------------------------------------------------|
| <a href="#">ConfigAdd</a> | Adds a statement to a system configuration file that has been loaded in memory. |

**Table 7** ▪ Advanced Configuration File Functions (cont.)

| Function                 | Description                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------|
| <b>ConfigDelete</b>      | Deletes an item from a system configuration file.                                       |
| <b>ConfigFileLoad</b>    | Loads a system configuration file into memory for editing.                              |
| <b>ConfigFileSave</b>    | Saves a system configuration file that has been loaded into memory with ConfigFileLoad. |
| <b>ConfigFind</b>        | Searches for an item in a system configuration file.                                    |
| <b>ConfigGetFileName</b> | Retrieves the fully qualified name of default system configuration file.                |
| <b>ConfigGetInt</b>      | Retrieves a value from a system configuration file.                                     |
| <b>ConfigMove</b>        | Moves an item within a system configuration file.                                       |
| <b>ConfigSetFileName</b> | Specifies the fully qualified file name of a system configuration file.                 |
| <b>ConfigSetInt</b>      | Sets a value in a system configuration file.                                            |

## Related Function

**Table 8** ▪ Related Function

| Function              | Description                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------|
| <b>SdShowFileMods</b> | Creates a dialog displaying proposed file changes and offering options on how to proceed. |

# Device Driver Functions

The functions below handle installing and uninstalling device drivers using Windows Driver Install Frameworks (DIFx). For more information on DIFx and DIFxAPI, see the MSDN Library.

**Table 9** ▪ Device Driver Functions

| Function                        | Description                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>DIFxDriverPackageGetPath</b> | Retrieves the path to the .inf file for driver package after a driver package is preinstalled in the driver store. |
| <b>DIFxDriverPackageInstall</b> | Preinstalls a driver package in the driver store and then installs the driver in the system.                       |

**Table 9** • Device Driver Functions (cont.)

| Function                           | Description                                                                                                                                                                     |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DIFxDriverPackagePreinstall</b> | Preinstalls a driver package for a Plug and Play (PnP) function driver in the driver store and installs the .inf file for the driver package in the system .inf file directory. |
| <b>DIFxDriverPackageUninstall</b>  | Uninstalls the specified driver package from the system and removes the driver package from the driver store.                                                                   |

## Dialog Functions

Some of the following functions create simple dialogs, such as Yes/No dialogs and message boxes. Several functions let you easily display various types of common dialogs. Other functions are script dialog (Sd) functions. Sd dialogs are created using special InstallScript definition functions that create a dialog with custom input. The dialogs then automatically return values to the script based on the selected action.

**Note** • Dialogs that have a Cancel button do not return a CANCEL value when that button is clicked. Instead, the *OnCanceling* event handler is called.

**Table 10** • Dialog Functions

| Function            | Project Type                                | Description                                                                                                                                                                                                             |
|---------------------|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AdminAskPath</b> | InstallScript MSI                           | Displays a dialog that prompts the end user to enter the path to a destination location for an administrative installation (when the end user runs an InstallScript MSI project's Setup.exe file with the /a argument). |
| <b>AskDestPath</b>  | InstallScript, InstallScript MSI            | Presents a dialog that requests destination path information.                                                                                                                                                           |
| <b>AskOptions</b>   | InstallScript, InstallScript MSI            | Presents a dialog that prompts the end user to select options by using check boxes or radio buttons.                                                                                                                    |
| <b>AskPath</b>      | InstallScript, InstallScript MSI            | Presents a dialog that prompts the end user to enter a path.                                                                                                                                                            |
| <b>AskText</b>      | InstallScript, InstallScript MSI            | Presents a dialog that prompts the end user to enter text.                                                                                                                                                              |
| <b>AskYesNo</b>     | Basic MSI, InstallScript, InstallScript MSI | Presents a message box that prompts the end user to respond to a question by clicking on a Yes or No button.                                                                                                            |

**Table 10** ▪ Dialog Functions (cont.)

| Function                | Project Type                                      | Description                                                                                                                                                                                                                                          |
|-------------------------|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EnterDisk</b>        | Basic MSI,<br>InstallScript,<br>InstallScript MSI | Presents a message box that prompts the end user for a specific disk.                                                                                                                                                                                |
| <b>EnterDiskError</b>   | Basic MSI,<br>InstallScript,<br>InstallScript MSI | Checks whether a specified path and file exists. The function displays an appropriate error message box if the file does not exist in the specified path; then it returns success or failure, depending on whether the specified file exists.        |
| <b>EnterLoginInfo</b>   | InstallScript,<br>InstallScript MSI               | Displays a dialog that enables the end user to specify a user name and password. Note that the dialog does not validate or use the specified information. In addition, the dialog does not perform any error checking for the specified information. |
| <b>EnterPassword</b>    | InstallScript,<br>InstallScript MSI               | Displays a dialog that queries the end user for a password; the characters that the end user types in the edit box are displayed as asterisks (*).                                                                                                   |
| <b>FeatureDialog</b>    | InstallScript,<br>InstallScript MSI               | Presents a dialog that enables end users to select features and specify a destination location.                                                                                                                                                      |
| <b>MessageBox</b>       | Basic MSI,<br>InstallScript,<br>InstallScript MSI | Presents a message in a message box.                                                                                                                                                                                                                 |
| <b>MessageBoxEx</b>     | Basic MSI,<br>InstallScript,<br>InstallScript MSI | Presents a message in a message box.                                                                                                                                                                                                                 |
| <b>RebootDialog</b>     | InstallScript,<br>InstallScript MSI               | Presents a message box that enables end users to choose to restart the computer.                                                                                                                                                                     |
| <b>SdAskDestPath</b>    | InstallScript,<br>InstallScript MSI               | Creates a dialog that enables end users to select an alternate destination path.                                                                                                                                                                     |
| <b>SdAskDestPath2</b>   | InstallScript,<br>InstallScript MSI               | Creates a dialog that enables end users to select an alternate destination path.                                                                                                                                                                     |
| <b>SdAskOptions</b>     | InstallScript,<br>InstallScript MSI               | Creates a dialog that has greater flexibility than the standard <b>AskOptions</b> function.                                                                                                                                                          |
| <b>SdAskOptionsList</b> | InstallScript,<br>InstallScript MSI               | Presents a dialog that enables end users to select and deselect items from a list.                                                                                                                                                                   |

**Table 10** • Dialog Functions (cont.)

| Function                       | Project Type                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SdBitmap</b>                | InstallScript,<br>InstallScript MSI | Displays a bitmap on a dialog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SdConfirmNewDir</b>         | InstallScript,<br>InstallScript MSI | Displays a message box that prompts the user to confirm the folder selection.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SdConfirmRegistration</b>   | InstallScript,<br>InstallScript MSI | Displays a message box that prompts the end user to confirm the information that was entered in dialogs presented by <b>SdRegisterUser</b> or <b>SdRegisterUserEx</b> .                                                                                                                                                                                                                                                                                                                                                    |
| <b>SdCustomerInformation</b>   | InstallScript,<br>InstallScript MSI | Displays a dialog that enables the end user to specify the user name and company name for the product being installed. The dialog may also include radio buttons that let the end user specify whether the product should be installed for all users or only the current user.                                                                                                                                                                                                                                             |
| <b>SdCustomerInformationEx</b> | InstallScript,<br>InstallScript MSI | Displays a dialog that enables the end user to specify the user name, company name, and serial number for the product being installed. The dialog may also include radio buttons that let the end user specify whether the product should be installed for all users or only the current user.                                                                                                                                                                                                                             |
| <b>SdDiskSpace2</b>            | InstallScript,<br>InstallScript MSI | Displays a dialog that shows either of the following: <ul style="list-style-type: none"> <li>• A list view of volumes, required space, available space, and the difference between available space and required space.</li> <li>• A warning message indicating that the target system does not have enough available space for the installation to take place. The dialog also displays a list view of volumes, required space, available space, and the difference between available space and required space.</li> </ul> |
| <b>SdDiskSpaceRequirements</b> | InstallScript,<br>InstallScript MSI | Displays a list of volumes, required space, available space, and the difference between available and required space.<br><br><b>SdDiskSpace2</b> supersedes this function.                                                                                                                                                                                                                                                                                                                                                 |
| <b>SdDisplayTopics</b>         | InstallScript,<br>InstallScript MSI | Displays a list of topics.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>SdExceptions</b>            | InstallScript,<br>InstallScript MSI | Displays a message box informing the end user that a shared, locked (in use), or read-only file has been encountered.                                                                                                                                                                                                                                                                                                                                                                                                      |

|-------------------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SdLogonUserInformation</b> | InstallScript,<br>InstallScript MSI | Displays a dialog that prompts the end user for existing user account information or new user information if an account is to be created during the installation.                                                                                                                                                                                                                                                                                       |
| <b>SdLogonUserListGroups</b>  | InstallScript,<br>InstallScript MSI | Displays a dialog that enables end users to select a group from a specified server and populate the Group field in the <b>SdLogonUserCreateUser</b> dialog.                                                                                                                                                                                                                                                                                             |
| <b>SdLogonUserListServers</b> | InstallScript,<br>InstallScript MSI | Displays a dialog that enables end users to browse for the domain or server with which the user account is associated.                                                                                                                                                                                                                                                                                                                                  |
| <b>SdLogonUserListUsers</b>   | InstallScript,<br>InstallScript MSI | Displays a dialog that enables end users to browse and select an existing user for a specified domain or server.                                                                                                                                                                                                                                                                                                                                        |
| <b>SdOptionsButtons</b>       | InstallScript,<br>InstallScript MSI | Displays a dialog with user-defined buttons that provide an end user with various options.                                                                                                                                                                                                                                                                                                                                                              |
| <b>SdOutOfDiskSpace</b>       | InstallScript MSI                   | When triggered by the Windows Installer's <code>INSTALLMESSAGE_OUTOFDISKSPACE</code> message, this dialog displays a message indicating that the target system is out of disk space.<br><br><b>SdDiskSpace2</b> supersedes this function.                                                                                                                                                                                                               |
| <b>SdPatchWelcome</b>         | InstallScript MSI                   | Creates a dialog that displays a welcome message to end users during a patch installation.                                                                                                                                                                                                                                                                                                                                                              |
| <b>SdRegisterUser</b>         | InstallScript,<br>InstallScript MSI | Displays a dialog that enables the end user to specify the user name and company name for the product being installed.                                                                                                                                                                                                                                                                                                                                  |
| <b>SdRegisterUserEx</b>       | InstallScript,<br>InstallScript MSI | Displays a dialog that enables the end user to specify the user name, company name, and serial number for the product being installed.                                                                                                                                                                                                                                                                                                                  |
| <b>SdRMFilesInUse</b>         | InstallScript MSI                   | Displays a dialog that includes a list box containing a list of the applications that are open and are locking files. The dialog also includes two radio buttons that allow end users to specify whether the installation should attempt to use the Restart Manager to shut down the applications that are locking files or attempting to overwrite the locked files (which most likely results in the need for a reboot to complete the installation). |
| <b>SdSelectFolder</b>         | InstallScript,<br>InstallScript MSI | Presents a dialog that enables end users to select a folder from a list of program folders.                                                                                                                                                                                                                                                                                                                                                             |

**Table 10** • Dialog Functions (cont.)

| Function                    | Project Type                        | Description                                                                                                                                                                                             |
|-----------------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SdSetupCompleteError</b> | InstallScript,<br>InstallScript MSI | Displays a dialog to inform the end user that the installation was interrupted before it could be completed.                                                                                            |
| <b>SdSetupType</b>          | InstallScript,<br>InstallScript MSI | Displays a dialog that enables the end user to select one of the three standard setup types: Typical, Compact, or Custom.                                                                               |
| <b>SdSetupType2</b>         | InstallScript,<br>InstallScript MSI | Displays a dialog that enables end users to select one of the two standard setup types: Typical or Custom.                                                                                              |
| <b>SdSetupTypeEx</b>        | InstallScript MSI                   | Displays a dialog that enables end users to select standard or custom setup types.                                                                                                                      |
| <b>SdShowAnyDialog</b>      | InstallScript,<br>InstallScript MSI | Displays a general-purpose dialog from a resource DLL. You cannot receive any input from the end user when showing a dialog with <b>SdShowAnyDialog</b> .                                               |
| <b>SdShowDlgEdit1</b>       | InstallScript,<br>InstallScript MSI | Displays a dialog that has one single-line edit field and other static controls.                                                                                                                        |
| <b>SdShowDlgEdit2</b>       | InstallScript,<br>InstallScript MSI | Displays a dialog that has two single-line edit fields and other static controls.                                                                                                                       |
| <b>SdShowDlgEdit3</b>       | InstallScript,<br>InstallScript MSI | Displays a dialog that has three single-line edit fields and other static controls.                                                                                                                     |
| <b>SdShowFileMods</b>       | InstallScript,<br>InstallScript MSI | Presents a dialog that previews the changes that may be made to a file and enables end users to approve the changes, reject the changes, or request that the changes be written to a file.              |
| <b>SdShowInfoList</b>       | InstallScript,<br>InstallScript MSI | Displays a scrollable list of messages in a dialog.                                                                                                                                                     |
| <b>SdShowMsg</b>            | InstallScript,<br>InstallScript MSI | Displays a message in a small window.                                                                                                                                                                   |
| <b>SdStartCopy</b>          | InstallScript,<br>InstallScript MSI | Presents a dialog that displays the options and settings that have been specified by the end user.                                                                                                      |
| <b>SdStartCopy2</b>         | InstallScript,<br>InstallScript MSI | Presents a dialog that informs the end user that the file transfer process is about to begin. The user can click the Back button to return to previous dialogs in order to change settings as required. |

**Table 10** • Dialog Functions (cont.)

| Function               | Project Type                                      | Description                                                                                                                                                               |
|------------------------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SdWelcome</b>       | InstallScript,<br>InstallScript MSI               | Displays a general-purpose greeting.                                                                                                                                      |
| <b>SdWelcomeMaint</b>  | InstallScript,<br>InstallScript MSI               | Displays a dialog for use at the beginning of a maintenance setup.                                                                                                        |
| <b>SelectDir</b>       | InstallScript,<br>InstallScript MSI               | Presents a dialog that enables end users to select a folder. SelectDir creates the folder if it does not exist.                                                           |
| <b>SelectDirEx</b>     | InstallScript,<br>InstallScript MSI               | Presents a dialog that enables end users to select a folder.                                                                                                              |
| <b>SelectFolder</b>    | InstallScript,<br>InstallScript MSI               | Presents a dialog that enables end users to select a folder from a list of program folders.                                                                               |
| <b>SetupType</b>       | InstallScript,<br>InstallScript MSI               | Presents a dialog that enables the end user to select a typical, compact, or custom setup.                                                                                |
| <b>SetupType2</b>      | InstallScript,<br>InstallScript MSI               | Presents a dialog that enables the end user to select one of the two standard setup types: Complete or Custom.                                                            |
| <b>SprintfBox</b>      | Basic MSI,<br>InstallScript,<br>InstallScript MSI | Returns a formatted string composed of one or more character, numeric, or string values.                                                                                  |
| <b>SQLBrowse</b>       | InstallScript,<br>InstallScript MSI               | Creates a dialog that enables the end user to bring up a list of all SQL Servers available on the network.<br><br><b>SQLBrowse2</b> supersedes this function.             |
| <b>SQLBrowse2</b>      | InstallScript,<br>InstallScript MSI               | Creates a dialog that lets an end user display a list of all database servers that are available on the network for the database technologies specified for a connection. |
| <b>SQLServerLogin</b>  | InstallScript,<br>InstallScript MSI               | Creates a dialog that is used by the script to specify SQL login credentials. These credentials include the login ID and password.                                        |
| <b>SQLServerSelect</b> | InstallScript,<br>InstallScript MSI               | Creates a dialog to specify a server to target.                                                                                                                           |

**Table 10** • Dialog Functions (cont.)

| Function                      | Project Type                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SQLServerSelectLogin</b>   | InstallScript,<br>InstallScript MSI | <p>Creates a login dialog that enables the targeted end user to specify which SQL Server should be used for the current connection, as well as which login credential should be used. The dialog displays a combo box that contains a list of SQL Servers accessed through DSNs. The end user can type a server name in the combo box or click the Browse button next to the combo box; clicking this button displays a list of all SQL Servers that are available on the network.</p> <p><b>SQLServerSelectLogin2</b> supersedes this function.</p>                                                                                                                                                                                                                        |
| <b>SQLServerSelectLogin2</b>  | InstallScript,<br>InstallScript MSI | <p>Creates a login dialog that is used by the default script. It lets the targeted end user specify which SQL Server should be used for the current connection, as well as which login credential should be used. The dialog displays a combo box that contains a list of SQL Servers accessed through DSNs. The end user can type a server name in the combo box or click the Browse button next to the Server Name combo box; clicking this button displays a list of all SQL Servers that are available on the network.</p> <p>This function also optionally shows the connection name that is associated with the connection information. In addition, it optionally enables end users to specify which database catalog should be used for the current connection.</p> |
| <b>SQLServerSelectLoginEx</b> | InstallScript,<br>InstallScript MSI | <p>Creates a login dialog that is used by the default script. It lets the targeted end user specify which SQL Server should be used for the current connection, as well as which login credential should be used. The dialog displays a combo box that contains a list of SQL Servers accessed through DSNs. The end user can type a server name in the combo box or click the Browse button next to the Server Name combo box; clicking this button displays a list of all SQL Servers that are available on the network.</p> <p>This function also shows the connection name that is associated with the connection information.</p> <p><b>SQLServerSelectLogin2</b> supersedes this function.</p>                                                                        |
| <b>Welcome</b>                | InstallScript,<br>InstallScript MSI | Presents a dialog that displays welcome information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

# Dialog Customization Functions

Use the following functions to create and customize new InstallScript dialogs, and to modify the text, controls, and behavior of InstallScript dialogs. Some of the functions handle custom dialog processing.

Any Windows dialog that you can create can be used in a setup script. The dialogs can have single and multiline edit boxes, single and multiselection list boxes, combo boxes, radio buttons, check boxes, and push buttons as standard controls. For more complex controls, advanced functions such as **CmdGetHwndDlg**, **LOWORD**, and **HIWORD** are provided.

**Table 11** • Dialog Customization Functions

| Function                        | Description                                                                                 |
|---------------------------------|---------------------------------------------------------------------------------------------|
| <b>CmdGetHwndDlg</b>            | Retrieves the handle of a dialog.                                                           |
| <b>CtrlClear</b>                | Deletes the contents of an edit, static, list box, or combo box control.                    |
| <b>CtrlDir</b>                  | Fills a list box or combo box with either a directory listing or a file listing.            |
| <b>CtrlGetCurSel</b>            | Returns the selected item from a list box or combo box.                                     |
| <b>CtrlGetDlgItem</b>           | Retrieves the window handle of a control in a custom dialog.                                |
| <b>CtrlGetMLEText</b>           | Retrieves the text from a multi-line edit or static field.                                  |
| <b>CtrlGetMultCurSel</b>        | Returns the selected items from a multi-selection list box.                                 |
| <b>CtrlGetState</b>             | Retrieves the state of a radio button, check box, or push button control from a dialog.     |
| <b>CtrlGetSubCommand</b>        | Retrieves the operation performed on the control after a <b>WaitOnDialog</b> function call. |
| <b>CtrlGetText</b>              | Retrieves the text from an edit field, a static field, or the edit field of a combo box.    |
| <b>CtrlGetUrlForLinkClicked</b> | Retrieves the URL for a link that an end user clicked.                                      |
| <b>CtrlPGroups</b>              | Retrieves a list of program group names that exist on the target system.                    |
| <b>CtrlSelectText</b>           | Selects the text displayed in an edit field.                                                |
| <b>CtrlSetCurSel</b>            | Finds and sets the current selection in a list box or combo box.                            |
| <b>CtrlSetFont</b>              | Specifies a font for a control in the dialog.                                               |
| <b>CtrlSetList</b>              | Places the contents of a list into a list box or combo box.                                 |
| <b>CtrlSetMLEText</b>           | Sets the text in a multi-line edit field.                                                   |

**Table 11** • Dialog Customization Functions (cont.)

| Function                    | Description                                                                                                                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CtrlSetMultCurSel</b>    | Sets the current selection in a multi-selection list box.                                                                                                                                                                                              |
| <b>CtrlSetState</b>         | Sets the current state of a check box, radio button, or push button control.                                                                                                                                                                           |
| <b>CtrlSetText</b>          | Sets the text in an edit field, a static text field, or the edit field of a combo box.                                                                                                                                                                 |
| <b>DefineDialog</b>         | Registers a custom dialog with InstallShield.                                                                                                                                                                                                          |
| <b>DialogSetFont</b>        | Sets the font for dialogs displayed during the setup.                                                                                                                                                                                                  |
| <b>DialogSetInfo</b>        | Changes display elements in the dialogs presented by some built-in dialog functions.                                                                                                                                                                   |
| <b>EndCurrentDialog</b>     | Closes the currently displayed dialog by calling <b>EndDialog</b> .                                                                                                                                                                                    |
| <b>EndDialog</b>            | Closes a custom dialog.                                                                                                                                                                                                                                |
| <b>EzDefineDialog</b>       | Registers a custom dialog with InstallShield.                                                                                                                                                                                                          |
| <b>GetCurrentDialogName</b> | Retrieves the name of the currently displayed dialog as it was specified in the call to <b>EzDefineDialog</b> when the dialog was defined.                                                                                                             |
| <b>GetFont</b>              | Retrieves the handle of a font.                                                                                                                                                                                                                        |
| <b>HIWORD</b>               | Retrieves the high-order word from a 32-bit integer.                                                                                                                                                                                                   |
| <b>LOWORD</b>               | Retrieves the low-order word from a 32-bit integer.                                                                                                                                                                                                    |
| <b>ReleaseDialog</b>        | Frees the memory associated with a dialog.                                                                                                                                                                                                             |
| <b>SdGeneralInit</b>        | Provides standard dialog initialization, including setting the enable or disable state of the Next, Back, and Cancel buttons. This function also replaces all %P, %VS, and %VI instances on static controls with control IDs 700 through 724, and 202. |
| <b>SdInit</b>               | Prepares a setup for calls to Sd dialog functions.                                                                                                                                                                                                     |
| <b>SdLoadString</b>         | Returns the string value associated with a specified resource ID.                                                                                                                                                                                      |
| <b>SdMakeName</b>           | Creates a section name for a custom dialog. This section name is used in writing to and reading from an .iss file, which is used by InstallShield Silent.                                                                                              |
| <b>SdProductName</b>        | Inserts your product name in certain static fields of the script dialogs.                                                                                                                                                                              |

**Table 11** • Dialog Customization Functions (cont.)

| Function                       | Description                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SdSubstituteProductInfo</b> | Replaces any occurrences of the %P, %VS, and %VI placeholders with the values of the system variables IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and IFX_INSTALLED_DISPLAY_VERSION. You can use this function before calling a function, such as MessageBox, that does not automatically perform this replacement before displaying strings. |
| <b>SilentReadData</b>          | Instructs InstallShield Silent to read the .iss file dialog data for a custom dialog.                                                                                                                                                                                                                                                                    |
| <b>SilentWriteData</b>         | Instructs InstallShield Silent to write to the .iss file dialog data for a custom dialog.                                                                                                                                                                                                                                                                |
| <b>WaitOnDialog</b>            | Presents a custom dialog.                                                                                                                                                                                                                                                                                                                                |

## Extensibility Functions

Extensibility functions allow you to call functions in dynamic-link libraries, call Windows APIs, or launch another application or setup script. The UseDLL and UnUseDLL functions allow you to load or unload a DLL into memory and make use of the DLL. The LaunchApp and LaunchAppAndWait functions allow you to launch another Windows or DOS application while the script is still executing.

**Table 12** • Extensibility Functions

| Function                               | Description                                                                                                                                                                                                                                                                                  |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CallDLLFx</b>                       | Calls a function from an external DLL.                                                                                                                                                                                                                                                       |
| <b>Delay</b>                           | Delays the execution of the setup script.                                                                                                                                                                                                                                                    |
| <b>LaunchApp</b>                       | Launches another program. <b>LaunchApplication</b> supersedes this function.                                                                                                                                                                                                                 |
| <b>LaunchAppAndWait</b>                | Launches another program and waits for that program to terminate. <b>LaunchApplication</b> supersedes this function.                                                                                                                                                                         |
| <b>LaunchAppAndWaitInitStartupInfo</b> | Initializes the LAAW_STARTUPINFO and LAAW_PARAMETERS system variables to the appropriate default values. <b>LaunchApplicationInit</b> supersedes this function.                                                                                                                              |
| <b>LaunchApplication</b>               | Uses either the Windows API function <b>CreateProcess</b> or the Windows API function <b>ShellExecuteEx</b> to launch the specified application. After the application is launched, the installation can optionally call <b>WaitForApplication</b> to wait for the application to terminate. |
| <b>LaunchApplicationInit</b>           | Initializes the LAAW_STARTUPINFO and LAAW_PARAMETERS system variables to the appropriate default values. This function is called automatically during installation initialization.                                                                                                           |
| <b>UnUseDLL</b>                        | Unloads a DLL from memory.                                                                                                                                                                                                                                                                   |

**Table 12** • Extensibility Functions (cont.)

| Function                  | Description                                                    |
|---------------------------|----------------------------------------------------------------|
| <b>UseDLL</b>             | Loads a DLL into memory.                                       |
| <b>WaitForApplication</b> | Waits for a running application to terminate before returning. |

## Feature Functions

The functions below allow you to control file media and to create and process script-created feature sets.

**Table 13** • Feature Functions

| Function                          | Project Type                        | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FeatureAddCost</b>             | InstallScript                       | Specifies that the feature includes additional installation operations that should be accounted for when updating the progress bar during the installation.<br><br><br><b>Note</b> • This function is supported only for file media. Use <b>FeatureGetData</b> or <b>FeatureSetData</b> to set the size of script-created features. |
| <b>FeatureAddItem</b>             | InstallScript,<br>InstallScript MSI | Adds a new feature to a script-created feature set.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>FeatureAddUninstallCost</b>    | InstallScript                       | Specifies that the feature includes additional uninstallation operations that must be accounted for when updating the progress bar during uninstallation.                                                                                                                                                                                                                                                            |
| <b>FeatureCompareSizeRequired</b> | InstallScript,<br>InstallScript MSI | Determines if enough free disk space exists for the selected features.                                                                                                                                                                                                                                                                                                                                               |
| <b>FeatureDialog</b>              | InstallScript,<br>InstallScript MSI | Presents a dialog that enables end users to select features and specify a destination location.                                                                                                                                                                                                                                                                                                                      |
| <b>FeatureError</b>               | InstallScript,<br>InstallScript MSI | Returns additional error information when a feature function fails.                                                                                                                                                                                                                                                                                                                                                  |
| <b>FeatureErrorInfo</b>           | InstallScript,<br>InstallScript MSI | Returns additional error information when a feature function fails.                                                                                                                                                                                                                                                                                                                                                  |
| <b>FeatureFileEnum</b>            | InstallScript,<br>InstallScript MSI | Builds a list of the files in a component associated with the specified feature.                                                                                                                                                                                                                                                                                                                                     |
| <b>FeatureFileInfo</b>            | InstallScript,<br>InstallScript MSI | Retrieves information on file in the file media that is referenced within the function.                                                                                                                                                                                                                                                                                                                              |

**Table 13** • Feature Functions (cont.)

| Function                     | Project Type                        | Description                                                                                                                                                                        |
|------------------------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FeatureFilterLanguage</b> | InstallScript,<br>InstallScript MSI | Enables and disables filtering based on language.                                                                                                                                  |
| <b>FeatureFilterOS</b>       | InstallScript,<br>InstallScript MSI | Enables and disables filtering based on operating system (OS).                                                                                                                     |
| <b>FeatureGetCost</b>        | InstallScript,<br>InstallScript MSI | Retrieves the total space, in kilobytes (KB), required on the target drive for the specified feature.<br><br><b>FeatureGetCostEx</b> supersedes this function.                     |
| <b>FeatureGetCostEx</b>      | InstallScript,<br>InstallScript MSI | Retrieves the cost of the specified feature (in bytes) using the nvCostHigh and nvCostLow parameters.                                                                              |
| <b>FeatureGetData</b>        | InstallScript,<br>InstallScript MSI | Retrieves information about a feature.                                                                                                                                             |
| <b>FeatureGetItemSize</b>    | InstallScript,<br>InstallScript MSI | Determines the size of a specified feature.                                                                                                                                        |
| <b>FeatureGetTotalCost</b>   | InstallScript,<br>InstallScript MSI | Determines the total space required for the feature installations and uninstallations that have been specified.<br><br><b>FeatureGetCostEx</b> supersedes this function.           |
| <b>FeatureInitialize</b>     | InstallScript                       | Supported only for compatibility with scripts created in earlier versions of InstallShield. It is recommended that you avoid using multiple file media libraries in InstallShield. |
| <b>FeatureIsItemSelected</b> | InstallScript,<br>InstallScript MSI | Determines if the specified feature has been selected by the end user.                                                                                                             |
| <b>FeatureListItems</b>      | InstallScript,<br>InstallScript MSI | Creates a list of the features in a file media library or a script-created feature set.                                                                                            |
| <b>FeatureLoadTarget</b>     | InstallScript                       | Called automatically during the initialization of any installation for which a valid log file exists.                                                                              |
| <b>FeatureMoveData</b>       | InstallScript                       | Transfers and decompresses files associated with selected features in the file media.                                                                                              |

**Table 13** • Feature Functions (cont.)

| Function                             | Project Type                        | Description                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FeaturePatch</b>                  | InstallScript                       | Called only in installations that use differential media. This function causes the next call to <b>FeatureTransferData</b> or <b>FeatureMoveData</b> to reinstall all features that are already installed when <b>FeatureTransferData</b> is called, including all of the maintenance/uninstallation feature's files except for Data1.hdr, Data1.cab, and Layout.bin. |
| <b>FeatureReinstall</b>              | InstallScript,<br>InstallScript MSI | Configures the setup so that the next call to <b>FeatureTransferData</b> performs the file transfer that was specified the last time the setup was run.                                                                                                                                                                                                               |
| <b>FeatureRemoveAll</b>              | InstallScript,<br>InstallScript MSI | Configures the setup so that the next call to <b>FeatureTransferData</b> uninstalls the setup.                                                                                                                                                                                                                                                                        |
| <b>FeatureRemoveAllInLogOnly</b>     | InstallScript                       | Called during an update installation to force the removal of all features that are not in the current media but were installed previously, as recorded in the setup log file.                                                                                                                                                                                         |
| <b>FeatureRemoveAllInMedia</b>       | InstallScript                       | Used during a maintenance installation to force the removal of all features that are in the current media and were installed previously. This function is generally called when the user selects the Remove option on the <b>SdWelcomeMaint</b> dialog.                                                                                                               |
| <b>FeatureRemoveAllInMediaAndLog</b> | InstallScript                       | Called during an update installation to force the removal of all features that were installed previously—both those that are in the current media, and those that are not in the current media but are recorded in the setup log file.                                                                                                                                |
| <b>FeatureSaveTarget</b>             | InstallScript,<br>InstallScript MSI | Retrieves the current values of all text substitutions used by the installation project and stores them in the installation log file.                                                                                                                                                                                                                                 |
| <b>FeatureSelectItem</b>             | InstallScript,<br>InstallScript MSI | Selects or deselects features.                                                                                                                                                                                                                                                                                                                                        |
| <b>FeatureSelectNew</b>              | InstallScript                       | Sets the selection status of all new features to either selected or unselected.                                                                                                                                                                                                                                                                                       |
| <b>FeatureSetData</b>                | InstallScript,<br>InstallScript MSI | Sets properties and data for the specified feature.                                                                                                                                                                                                                                                                                                                   |
| <b>FeatureSetTarget</b>              | InstallScript,<br>InstallScript MSI | Specifies a user-defined variable for a file media library.                                                                                                                                                                                                                                                                                                           |

**Table 13** • Feature Functions (cont.)

| Function                           | Project Type                                                                                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FeatureSetupTypeEnum</b>        | InstallScript,<br>InstallScript MSI                                                                                                                                          | Enumerates the setup types associated with the specified file media library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>FeatureSetupTypeGetData</b>     | InstallScript,<br>InstallScript MSI                                                                                                                                          | Retrieves data associated with a specified setup type that has been created in the InstallShield interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>FeatureSetupTypeSet</b>         | InstallScript,<br>InstallScript MSI                                                                                                                                          | Selects all features associated with the specified setup type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|----------------------|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>SdSetupType2</b>  | InstallScript,<br>InstallScript MSI | Displays a dialog that enables the end user to select one of the two standard setup types: Typical or Custom.                 |
| <b>SdSetupTypeEx</b> | InstallScript MSI                   | Displays a dialog that enables the end user to select the setup type when you specify setup types beyond Complete and Custom. |

## Script-Created Feature Set vs. File Media Library

You can create features at run time by calling the **FeatureAddItem** function in your setup script. These script-created features reside only in memory and have no direct connection to a file media library. Unlike the information stored in a file media library, script-created features are not—and cannot be—directly associated with components or a setup type.

However, script-created features provide a convenient way of displaying feature-like options for the end user. After the end user makes feature selections in feature dialogs, you can test the script-created features' selection status and use the result as the basis for carrying out some action. For example, you might want to install files with **XCopyFile** or **VerUpdateFile**, select features in the file media library, or create or edit a file.

### Building a Script-Created Feature

To build a new script-created feature, call the **FeatureAddItem** function. Then, set and access properties for the script-created feature using the **InstallScript** feature functions much as you would for features in a file media library (exceptions noted below).

### Referring to Script-Created Feature Sets

Script-created features are often referred to collectively as a "script-created feature set." The reason is that they are often handled just like file media library features by feature functions. You must treat all features as a set when you pass their media name to the feature functions.

**Note** • You create the media name in the first parameter of **FeatureAddItem**. Use this value when you create features and subfeatures as part of the same "script-created feature set" and when you refer to existing script-created features in your script.

### Using Feature Functions

Since the two types of features are so different, you call some of the feature functions differently depending on whether you are working with a script-created feature or a feature in a file media library.

#### File Media Library and Script-Created Feature Set Functions

These functions can be used on both a feature in a file media library or on a script-created feature:

- **FeatureGetData**
- **FeatureSetData**

## File Media Library Functions

These functions work only with features in a file media library, but not with script-created features:

- [FeatureCompareSizeRequired](#)
- [FeatureFilterLanguage](#)
- [FeatureFilterOS](#)
- [FeatureSetTarget](#)
- [FeatureSetupTypeEnum](#)
- [FeatureSetupTypeGetData](#)
- [FeatureSetupTypeSet](#)
- [FeatureTransferData](#)

## Script-Created Feature Set Function

The [FeatureAddItem](#) function works exclusively with script-created feature sets.

## File Media Library

The file media library contains your product's files and all the information that you entered in the InstallShield interface about your installation's component, feature, and setup type settings.

The file media library is created when you create a release for your project. It is defined by `Data1.hdr`, the InstallScript header file. It also has a media name, the default value of which is contained in the `MEDIA` system variable.

You can set and access information in your file media library using the InstallScript feature functions.

**Note** • Some InstallScript feature functions are specifically reserved for use with script-created features.

## File and Folder Functions

File and folder functions provide a comprehensive way to work with text files, binary files, and folders. Many of the functions use the variables `TARGETDIR` (in InstallScript projects), `INSTALLDIR` (in InstallScript MSI and Basic MSI projects) and `SRCDIR` as the paths and accept only file names as parameters. Wild-card characters are also accepted where appropriate.

**Table 14** • File and Folder Functions

| Function                        | Description                                          |
|---------------------------------|------------------------------------------------------|
| <a href="#">ChangeDirectory</a> | Makes the specified directory the current directory. |
| <a href="#">CloseFile</a>       | Closes an open file.                                 |

**Table 14** • File and Folder Functions (cont.)

| Function                 | Description                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CopyFile</b>          | Copies a file from one folder to another.                                                                                                                                                                                                                                                                                   |
| <b>CreateDir</b>         | Creates a new folder.                                                                                                                                                                                                                                                                                                       |
| <b>CreateFile</b>        | Creates a file with the specified file name.                                                                                                                                                                                                                                                                                |
| <b>DeleteDir</b>         | Deletes a folder.                                                                                                                                                                                                                                                                                                           |
| <b>DeleteFile</b>        | Deletes a file.                                                                                                                                                                                                                                                                                                             |
| <b>ExistsDir</b>         | Determines whether or not the specified directory exists.                                                                                                                                                                                                                                                                   |
| <b>ExistsDisk</b>        | Determines whether or not the specified disk exists.                                                                                                                                                                                                                                                                        |
| <b>FileCompare</b>       | Compares one file with another.                                                                                                                                                                                                                                                                                             |
| <b>FileDeleteLine</b>    | Deletes a line in a text file.                                                                                                                                                                                                                                                                                              |
| <b>FileGrep</b>          | Searches a text file for specified text.                                                                                                                                                                                                                                                                                    |
| <b>FileInsertLine</b>    | Inserts a line in a text file.                                                                                                                                                                                                                                                                                              |
| <b>FindAllDirs</b>       | Finds all subfolders under the specified folder.                                                                                                                                                                                                                                                                            |
| <b>FindAllFiles</b>      | Finds all files in the specified folder and its subfolders that match a file specification.                                                                                                                                                                                                                                 |
| <b>FindFile</b>          | Finds the first file in the specified folder that matches a file specification.                                                                                                                                                                                                                                             |
| <b>GetFileInfo</b>       | Retrieves a file's attributes, date, time, and size.                                                                                                                                                                                                                                                                        |
| <b>GetLine</b>           | Retrieves a line of text from an open file.                                                                                                                                                                                                                                                                                 |
| <b>GetTempFileNameIS</b> | Calls the Windows API <b>GetTempFileName</b> to create a temporary file and perform related actions. Note that unlike <b>GetTempFileName</b> , <b>GetTempFileNameIS</b> creates the folder specified by szPathName if it does not already exist.                                                                            |
| <b>Is</b>                | Provides file and path checking services, searches for a math coprocessor, tests for administrator privileges, determines whether a particular version of the .NET Framework or a language pack is present on the target system, determines whether Microsoft Windows is running from a shared copy on a network, and more. |
| <b>OpenFile</b>          | Opens an existing file.                                                                                                                                                                                                                                                                                                     |
| <b>OpenFileMode</b>      | Sets the mode in which files will be opened with the OpenFile function.                                                                                                                                                                                                                                                     |
| <b>ReadBytes</b>         | Reads the specified number of bytes from a binary file.                                                                                                                                                                                                                                                                     |

**Table 14** • File and Folder Functions (cont.)

| Function                    | Description                                                                                                                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RenameFile</b>           | Renames a file.                                                                                                                                                                               |
| <b>SeekBytes</b>            | Positions the file pointer in a binary file.                                                                                                                                                  |
| <b>SetFileInfo</b>          | Sets the attributes, date, and time of a file.                                                                                                                                                |
| <b>SetObjectPermissions</b> | Sets permissions for a file, a folder, or a registry key. The file, folder, or registry key can be installed as part of your installation, or it can be already present on the target system. |
| <b>WriteBytes</b>           | Writes a specified number of bytes to a binary file at the current file pointer location.                                                                                                     |
| <b>WriteLine</b>            | Writes a string to a text file.                                                                                                                                                               |
| <b>XCopyFile</b>            | Copies one or more files from a source folder to a target folder, including subfolders if specified.                                                                                          |

## Related Function

**Table 15** • Related Function

| Function         | Description                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>SelectDir</b> | Presents a dialog that enables end users to select a folder. <b>SelectDir</b> creates the folder if it does not exist. |

# Information Functions

The following information functions provide data about resources that are available in the operating environment: disk space, memory, and operating mode.

**Table 16** • Information Functions

| Function              | Description                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------|
| <b>GetDiskInfo</b>    | Gets information about a specified disk drive.                                            |
| <b>GetDiskSpace</b>   | Returns the number of bytes available (unused) on the specified disk (up to 2 gigabytes). |
| <b>GetDiskSpaceEx</b> | Returns the amount of free space on a disk in bytes, kilobytes, megabytes, or gigabytes.  |
| <b>GetEnvVar</b>      | Returns the current value of an environment variable.                                     |

**Table 16** • Information Functions (cont.)

| Function                       | Description                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>GetExtendedErrInfo</b>      | Returns the error information that was set by <b>SetExtendedErrInfo</b> .                                                                                                                                                                                                                                                   |
| <b>GetExtents</b>              | Returns the dimensions of the screen.                                                                                                                                                                                                                                                                                       |
| <b>GetMemFree</b>              | This function is obsolete and should not be used.                                                                                                                                                                                                                                                                           |
| <b>GetSystemInfo</b>           | Retrieves system information.                                                                                                                                                                                                                                                                                               |
| <b>GetTrueTypeFontFileInfo</b> | Returns information about a particular TrueType font file.                                                                                                                                                                                                                                                                  |
| <b>GetValidDrivesList</b>      | Returns a listing of all available drives on the target system.                                                                                                                                                                                                                                                             |
| <b>GetWindowHandle</b>         | Returns the handle of the main installation window.                                                                                                                                                                                                                                                                         |
| <b>Is</b>                      | Provides file and path checking services, searches for a math coprocessor, tests for administrator privileges, determines whether a particular version of the .NET Framework or a language pack is present on the target system, determines whether Microsoft Windows is running from a shared copy on a network, and more. |
| <b>SetExtendedErrInfo</b>      | Sets error information, which can be retrieved by <b>GetExtendedErrInfo</b> .                                                                                                                                                                                                                                               |
| <b>SetInstallationInfo</b>     | Sets the values of the system variables IFX_COMPANY_NAME, IFX_PRODUCT_NAME, IFX_PRODUCT_VERSION, and IFX_PRODUCT_KEY.                                                                                                                                                                                                       |

## Initialization File Functions

Initialization file functions obtain information from and copy information to the initialization and profile files. An initialization file is a special ASCII file that contains key name-value pairs. The key name-value pairs represent run-time options for applications. You can also access and update private initialization file and system initialization files. The following list briefly describes each initialization file function.

**Table 17** • Initialization File Functions

| Function                 | Description                                                       |
|--------------------------|-------------------------------------------------------------------|
| <b>AddProfString</b>     | Adds a non-unique key to a section of the .ini file.              |
| <b>GetProfInt</b>        | Returns an integer from an .ini file.                             |
| <b>GetProfString</b>     | Returns a string from an .ini file.                               |
| <b>GetProfStringList</b> | Retrieves lists of key names and string values from an .ini file. |
| <b>ReplaceProfString</b> | Replaces a string in a profile (.ini) file.                       |

**Table 17** • Initialization File Functions (cont.)

| Function               | Description                                            |
|------------------------|--------------------------------------------------------|
| <b>WriteProfInt</b>    | Writes a string with an integer value to an .ini file. |
| <b>WriteProfString</b> | Writes a string to an .ini file.                       |

## Related Function

**Table 18** • Related Function

| Function              | Description                                                                               |
|-----------------------|-------------------------------------------------------------------------------------------|
| <b>SdShowFileMods</b> | Creates a dialog displaying proposed file changes and offering options on how to proceed. |

# List Processing Functions

Lists are used to store groups of related information. In InstallScript, there are two types of lists: string lists and number lists. Two sets of functions are provided to work with lists, one for each list type. List functions that end with "Item" operate with number lists. List functions that end with "String" operate with string lists. You cannot use number list functions on string lists and vice versa. Below are the functions to implement lists in a setup script.

**Table 19** • List Processing Functions

| Function                 | Description                                                           |
|--------------------------|-----------------------------------------------------------------------|
| <b>ListAddItem</b>       | Adds an item to a list.                                               |
| <b>ListAddString</b>     | Adds a string to a list.                                              |
| <b>ListCount</b>         | Returns the number of string or numeric elements in a specified list. |
| <b>ListCreate</b>        | Creates a new string or number list.                                  |
| <b>ListCurrentItem</b>   | Returns the current item in a list.                                   |
| <b>ListCurrentString</b> | Returns the current string in a list.                                 |
| <b>ListDeleteItem</b>    | Deletes the current item in a list.                                   |
| <b>ListDeleteString</b>  | Deletes the current string in a list.                                 |
| <b>ListDestroy</b>       | Destroys a list.                                                      |
| <b>ListFindItem</b>      | Makes the specified item the current item in a numeric list.          |

**Table 19** • List Processing Functions (cont.)

| Function                      | Description                                                                                                                                                                  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ListFindKeyValueString</b> | Searches a string or number list for a specified value. It returns a value from an additional list that corresponds with the position of the found string in the first list. |
| <b>ListFindString</b>         | Makes the specified item the current item in a string list.                                                                                                                  |
| <b>ListGetFirstItem</b>       | Retrieves the first element from a number list.                                                                                                                              |
| <b>ListGetFirstString</b>     | Retrieves the first string from a string list.                                                                                                                               |
| <b>ListGetNextItem</b>        | Retrieves the element after the current element from a number list.                                                                                                          |
| <b>ListGetNextString</b>      | Retrieves the element after the current element from a string list.                                                                                                          |
| <b>ListReadFromFile</b>       | Reads a text file into a list.                                                                                                                                               |
| <b>ListSetCurrentItem</b>     | Sets the current element of a number list.                                                                                                                                   |
| <b>ListSetCurrentString</b>   | Sets the current element of a string list.                                                                                                                                   |
| <b>ListSetIndex</b>           | Uses an index to set the current element of a list.                                                                                                                          |
| <b>ListValid</b>              | Indicates whether the specified list is valid.                                                                                                                               |
| <b>ListValidType</b>          | Indicates whether the specified list is valid and is of the specified type.                                                                                                  |
| <b>ListWriteToFile</b>        | Writes a string list to a file.                                                                                                                                              |
| <b>ListWriteToFileEx</b>      | Writes or appends a string list to a text file as Unicode or ANSI, depending on the constants that you provide for the <code>nOptions</code> parameter.                      |

## Log File Functions

**Project** • This information applies to *InstallScript* projects.

Log file functions obtain information from and copy information to the custom logging section of the log file. Custom log file entries do not affect maintenance or uninstallation of the application unless you add code to the script to read custom values and perform actions based on those values. The log file functions cannot read data from or write data to the maintenance/uninstallation section of the log file (that is, the section where the setup

automatically writes data, such as the files that are installed and the registry entries that are created, and from which it automatically reads data during maintenance or uninstallation). The following list briefly describes each log file function.

**Table 20** ▪ Log File Functions

| Function                    | Description                                                    |
|-----------------------------|----------------------------------------------------------------|
| <b>LogReadCustomNumber</b>  | Reads numeric data from the log file's custom logging section. |
| <b>LogReadCustomString</b>  | Reads string data from the log file's custom logging section.  |
| <b>LogWriteCustomNumber</b> | Writes numeric data to the log file's custom logging section.  |
| <b>LogWriteCustomString</b> | Writes string data to the log file's custom logging section.   |

## Long File Name Functions

The following functions create long file names from short file names, convert short file names to long file names, and place double quotation marks around long file names so that operating systems that handle long file names can recognize them.

**Table 21** ▪ Log File Name Functions

| Function                     | Description                                                        |
|------------------------------|--------------------------------------------------------------------|
| <b>LongPathFromShortPath</b> | Creates a long file name from a short file name.                   |
| <b>LongPathToQuote</b>       | Inserts or removes double quotation marks around a long file name. |
| <b>LongPathToShortPath</b>   | Creates a short file name from a long file name.                   |

## Miscellaneous Functions

The following functions serve various purposes, such as low-level hardware interface, feature creation and manipulation, and user output.

**Table 22** ▪ Miscellaneous Functions

| Function             | Description                                                     |
|----------------------|-----------------------------------------------------------------|
| <b>Do</b>            | Executes the currently defined EXIT and HELP handlers.          |
| <b>DoInstall</b>     | Launches another InstallShield installation.                    |
| <b>FormatMessage</b> | Returns a string error message for a large negative error code. |

**Table 22** • Miscellaneous Functions (cont.)

| Function                    | Description                                                                                                                                                                                                                                                          |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Handler</b>              | This function is obsolete. Use <b>HandlerEx</b> instead.                                                                                                                                                                                                             |
| <b>HandlerEx</b>            | Specifies a label to branch to in response to exit and help events.                                                                                                                                                                                                  |
| <b>ISCompareServicePack</b> | Compares the Service Pack number installed on the target OS to a specified Service Pack number.                                                                                                                                                                      |
| <b>IsEmpty</b>              | Checks whether a variable of type VARIANT has been initialized.                                                                                                                                                                                                      |
| <b>MessageBeep</b>          | Produces a standard warning beep.                                                                                                                                                                                                                                    |
| <b>Resize</b>               | Resizes an InstallScript array.                                                                                                                                                                                                                                      |
| <b>SendMessage</b>          | Sends a Windows message to another window or application.                                                                                                                                                                                                            |
| <b>SetObjectPermissions</b> | Sets permissions for a file, a folder, or a registry key.                                                                                                                                                                                                            |
| <b>SizeOf</b>               | Returns the size of an InstallScript array.                                                                                                                                                                                                                          |
| <b>Sprintf</b>              | Returns a formatted string composed of one or more character, numeric, or string values.                                                                                                                                                                             |
| <b>SprintfMsiLog</b>        | Writes a message directly to the Windows Installer log file.                                                                                                                                                                                                         |
| <b>StreamFileFromBinary</b> | Streams a binary key with a file.                                                                                                                                                                                                                                    |
| <b>System</b>               | Reboots the computer.                                                                                                                                                                                                                                                |
| <b>VarInit</b>              | Initializes or reinitializes internal lists used by the <b>VarSave</b> and <b>VarRestore</b> functions. Calling this function effectively clears any information stored by previous <b>VarSave</b> calls and not yet used by subsequent <b>VarRestore</b> functions. |
| <b>VarRestore</b>           | Restores the values of the system variables SRCDIR, TARGETDIR (in InstallScript projects), and INSTALLDIR (in Basic MSI and InstallScript projects) that were saved by the last call to <b>VarSave</b> .                                                             |
| <b>VarSave</b>              | Saves the current value of the system variables SRCDIR, TARGETDIR (in InstallScript projects), and INSTALLDIR (in Basic MSI and InstallScript projects).                                                                                                             |

# Object Functions

The object functions are available to assist you with initializing objects, as well as obtaining and setting status information for objects.

**Table 23** • Object Functions

| Function                     | Description                                                                                                                                                                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CoCreateObject</b>        | Initializes a COM object and returns a reference that can be assigned to a variable of type OBJECT by using the set keyword.                                                                                                                                                             |
| <b>CoCreateObjectDotNet</b>  | <p>The <b>CoCreateObjectDotNet</b> function has been deprecated. Calling this function is the same as calling the <b>DotNetCoCreateObject</b> function with a null string ("") for the szAppDomain parameter.</p> <p>For more information, see <a href="#">DotNetCoCreateObject</a>.</p> |
| <b>CoGetObject</b>           | Returns a reference to the specified COM object (as Visual Basic's GetObject function does); that reference can be assigned to a variable of type OBJECT by using the set keyword.                                                                                                       |
| <b>DotNetCoCreateObject</b>  | Calls functions in .NET assemblies without the assembly being registered for COM interoperability. This function, unlike the <b>CoCreateObjectDotNet</b> function, lets you specify the .NET application domain in which the .NET assemblies should be loaded and run.                   |
| <b>DotNetUnloadAppDomain</b> | Unloads the specified .NET application domain and releases any assemblies that are currently loaded into the specified application domain.                                                                                                                                               |
| <b>GetObject</b>             | Initializes an object and returns a reference that can be assigned to a variable of type OBJECT by using the set keyword.                                                                                                                                                                |
| <b>GetObjectByIndex</b>      | Finds the installation's or object's subobject that is specified by nIndex and returns a reference that can be assigned to a variable of type OBJECT by using the set keyword.                                                                                                           |
| <b>GetObjectCount</b>        | Returns the number of subobjects contained by the object or installation.                                                                                                                                                                                                                |
| <b>GetStatus</b>             | Retrieves the current status of the object; that is, the current value of Status.Number.                                                                                                                                                                                                 |
| <b>IsObject</b>              | Checks whether a variable of type OBJECT has been assigned a reference to a valid object, using the <a href="#">CreateObject</a> or <a href="#">GetObject</a> functions.                                                                                                                 |
| <b>SetStatus</b>             | Called in an object script to set the object's Status.Number and Status.Description properties.                                                                                                                                                                                          |
| <b>SetStatusEx</b>           | Called in an object script to set the object's status properties.                                                                                                                                                                                                                        |

## Path Buffer Functions

The path buffer functions are available to assist you in working with strings that contain search paths. The path string functions work on a unique temporary string variable known as the path buffer. The path buffer is defined internally within InstallShield—all the path string functions act on the contents of the path buffer.

Path functions assist you in manipulating and building path strings. After you have created a path string, you can save it to the appropriate file.

**Table 24** • Path Buffer Functions

| Function          | Description                                                                          |
|-------------------|--------------------------------------------------------------------------------------|
| <b>PathAdd</b>    | Adds a path to the search path in the path buffer.                                   |
| <b>PathDelete</b> | Deletes a directory from the path buffer.                                            |
| <b>PathFind</b>   | Finds a specific path in the path buffer or any path that includes a specified name. |
| <b>PathGet</b>    | Retrieves the current value of the path buffer.                                      |
| <b>PathMove</b>   | Rearranges the path buffer.                                                          |
| <b>PathSet</b>    | Assigns a value to the path buffer.                                                  |

## Registry Functions

The following functions allow you to access the registry, read, create and delete registry keys, and establish registry-related parameters for uninstallation.

**Table 25** • Registry Functions

| Function                      | Description                                                                                                                                                                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CreateInstallationInfo</b> | Creates an application information key and a per application paths key for the program you are installing.                                                                                                                                                    |
| <b>CreateRegistrySet</b>      | Creates one or all of the sets of registry entries specified in the Resources pane's Registry Entries folder.                                                                                                                                                 |
| <b>DeinstallSetReference</b>  | This function is obsolete.<br><br>If you want to check whether a file is locked during uninstallation, write script code that calls the <b>Is</b> function with the <b>FILE_LOCKED</b> constant for the <b>nlsFlag</b> parameter and that responds as needed. |
| <b>DeinstallStart</b>         | This function is obsolete.                                                                                                                                                                                                                                    |

**Table 25** • Registry Functions (cont.)

| Function                       | Description                                                                                                                                  |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InstallationInfo</b>        | This function is obsolete. Use the <b>CreateInstallationInfo</b> function instead.                                                           |
| <b>MaintenanceStart</b>        | Enables uninstallation functionality by creating the <PRODUCT_GUID> registry keys.                                                           |
| <b>RegDBConnectRegistry</b>    | Opens a connection to a remote registry.                                                                                                     |
| <b>RegDBCopKeyKeys</b>         | Copies the registry keys and values under the key specified by szSourceKey to the key specified by szTargetKey.                              |
| <b>RegDBCopValues</b>          | Copies the registry values under the key specified by szSourceKey to the key specified by szTargetKey.                                       |
| <b>RegDBCreateKeyEx</b>        | Creates a key in the registry. Also enables you to associate a class object with a registry key (advanced users only).                       |
| <b>RegDBDeleteItem</b>         | Deletes values under the per application paths key or the application uninstallation key, depending on the value of nItem.                   |
| <b>RegDBDeleteKey</b>          | Deletes the specified key from the registry.                                                                                                 |
| <b>RegDBDeleteValue</b>        | Deletes a value from a specified registry key.                                                                                               |
| <b>RegDBDisconnectRegistry</b> | Closes the connection to a remote registry.                                                                                                  |
| <b>RegDBGetAppInfo</b>         | Retrieves a value from under the application information key.                                                                                |
| <b>RegDBGetDefaultRoot</b>     | Returns the root key that is used by the general registry-related functions.                                                                 |
| <b>RegDBGetItem</b>            | Retrieves values under the per-application paths key or the application uninstallation key.                                                  |
| <b>RegDBGetKeyValueEx</b>      | Retrieves a value from under a key in the registry.                                                                                          |
| <b>RegDBGetUninstCmdLine</b>   | Gets the registered command line for the uninstallation that is specified by szUninstallKey and returns the command line in svUninstCmdLine. |
| <b>RegDBKeyExist</b>           | Checks that a registry key exists.                                                                                                           |
| <b>RegDBQueryKey</b>           | Queries a key for its subkeys and value names.                                                                                               |
| <b>RegDBQueryKeyCount</b>      | Returns the number of subkeys or values under a specified key.                                                                               |

**Table 25** • Registry Functions (cont.)

| Function                                | Description                                                                                                          |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>RegDBQueryStringMultiStringCount</b> | Returns the number of strings contained in the multistring value specified by a certain value under a specified key. |
| <b>RegDBSetAppInfo</b>                  | Sets a value under the application information key.                                                                  |
| <b>RegDBSetDefaultRoot</b>              | Sets the root key.                                                                                                   |
| <b>RegDBSetItem</b>                     | Assign values under the per application paths key or the application uninstallation key.                             |
| <b>RegDBSetKeyValueEx</b>               | Sets registry entries.                                                                                               |
| <b>SetInstallationInfo</b>              | Specifies company and product information for use by CreateInstallationInfo.                                         |
| <b>SetObjectPermissions</b>             | Sets permissions for a file, a folder, or a registry key.                                                            |

## Service Functions

The following functions allow you to access the registry, read, create and delete registry keys, and establish registry-related parameters for uninstallation.

**Table 26** • Service Functions

| Function                      | Description                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ServiceAddService</b>      | Adds a service to the list of services that are registered on the target system.                                                                  |
| <b>ServiceExistsService</b>   | Determines whether the specified service is registered.                                                                                           |
| <b>ServiceGetServiceState</b> | Retrieves the state of the specified service.                                                                                                     |
| <b>ServiceInitParams</b>      | Initializes the SERVICE_IS_PARAMS system variable's members to default values. This function is called automatically during setup initialization. |
| <b>ServiceRemoveService</b>   | Removes a service from the target system.                                                                                                         |
| <b>ServiceStartService</b>    | Starts a service. If the service is running when the function is called, the installation stops it and then restarts it.                          |
| <b>ServiceStopService</b>     | Stops a service.                                                                                                                                  |

# Shared and Locked File Functions

A shared file is a file, such as a .dll, .vb, or driver that can be used by more than one application. InstallShield protects shared files from being removed during uninstallation.

Functions using the SHAREDFILE option consider all files to be shared files, and therefore increment registry reference counters for all files involved. InstallShield increments the registry reference counter by one if the file exists in the target directory and it has a reference count greater than 0. If the shared file does not exist in the target directory and it has no reference counter, InstallShield creates the counter and sets it to 1. If the shared file already exists in the target directory but has no reference counter, InstallShield creates the counter and initializes it to 2 as a precaution against accidental removal during uninstallation.

Shared files should not be updated when they are locked. Some InstallShield file transfer functions use the SHAREDFILE option so that .dll and .exe files that are locked during file transfer can be recorded and updated when Windows or the system restarts.

InstallShield considers a file locked when it is in use by an application or the system. Locked files are not necessarily shared files.

The following functions handle shared or locked files:

**Table 27** • Shared and Locked File Functions

| Function                    | Description                                                                                                                                                                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Is</b>                   | Provides file and path checking services, searches for a math coprocessor, tests for administrator privileges, determines whether a particular version of the .NET Framework or a language pack is present on the target system, determines whether Microsoft Windows is running from a shared copy on a network, and more. |
| <b>RebootDialog</b>         | Presents a dialog with which the end user can choose to restart Windows or reboot the computer.                                                                                                                                                                                                                             |
| <b>SdFinishReboot</b>       | Presents a dialog stating that the installation is complete and allowing the end user to choose to restart Windows or reboot the computer.                                                                                                                                                                                  |
| <b>SetObjectPermissions</b> | Sets permissions for a file, a folder, or a registry key.                                                                                                                                                                                                                                                                   |
| <b>VerUpdateFile</b>        | Updates files using version resource information. Allows updating of locked .dll and .exe files and incrementing of registry reference counters for all files involved.                                                                                                                                                     |
| <b>XCopyFile</b>            | Copies files and subdirectories from the source directory to the target directory. Combines shared file and locked file handling by causing XCopyFile to treat all files as shared, and to record locked .dll and .exe files for update when Windows or the system restarts.                                                |

# Shell Functions

Shell functions create program folders, delete existing program folders, and add items to existing program folders. At the end of the setup, add the application to the appropriate program folder to allow the user to access your software immediately. The following functions also support various icon options.

**Table 28** • Shell Functions

| Function                    | Description                                                                                                                                                                                                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AddFolderIcon</b>        | Adds a shortcut or program folder to locations such as the Start menu, the Programs menu, or the desktop.<br><br><b>CreateShortcut</b> supersedes this function.                                                                                                      |
| <b>CreateProgramFolder</b>  | Creates a program folder.<br><br><b>CreateShortcutFolder</b> supersedes this function.                                                                                                                                                                                |
| <b>CreateShortcut</b>       | Adds a shortcut or program folder to locations such as the Start menu, the Programs menu, or the desktop.<br><br>Optionally sets Windows Shell properties for the shortcut to configure behavior such as disabling the ability to pin the shortcut to the Start menu. |
| <b>CreateShortcutFolder</b> | Creates a program folder.                                                                                                                                                                                                                                             |
| <b>DeleteFolderIcon</b>     | Removes a shortcut from a folder.<br><br><b>DeleteShortcut</b> supersedes this function.                                                                                                                                                                              |
| <b>DeleteProgramFolder</b>  | Removes a shortcut folder (that is, a subfolder of the Start menu's Programs folder) and its contents, including all shortcuts and all of the shortcut folder's subfolders and their contents.<br><br><b>DeleteShortcutFolder</b> supersedes this function.           |
| <b>DeleteShortcut</b>       | Removes a shortcut from a folder.                                                                                                                                                                                                                                     |
| <b>DeleteShortcutFolder</b> | Removes a shortcut folder (that is, a subfolder of the Start menu's Programs folder) and its contents, including all shortcuts and all of the shortcut folder's subfolders and their contents.                                                                        |
| <b>GetFolderNameList</b>    | Retrieves all subfolder names and shortcuts in the specified folder.                                                                                                                                                                                                  |
| <b>GetShortcutInfo</b>      | Returns information about a specified shortcut or subfolder.                                                                                                                                                                                                          |
| <b>ProgDefGroupType</b>     | Sets the value of the ALLUSERS system variable.                                                                                                                                                                                                                       |
| <b>QueryProgItem</b>        | Returns information about a specified shortcut or subfolder.<br><br><b>GetShortcutInfo</b> supersedes this function.                                                                                                                                                  |

**Table 28** ▪ Shell Functions (cont.)

| Function                   | Description                                                                                           |
|----------------------------|-------------------------------------------------------------------------------------------------------|
| <b>QueryShellMgr</b>       | Returns the name of the current shell manager.                                                        |
| <b>ReplaceFolderIcon</b>   | Replaces a shortcut in a specified folder.<br><b>ReplaceShortcut</b> supersedes this function.        |
| <b>ReplaceShortcut</b>     | Replaces a shortcut in a specified folder.                                                            |
| <b>SelectFolder</b>        | Presents a dialog that enables end users to select a folder from a list of program folders.           |
| <b>SetShortcutProperty</b> | Sets one or more shortcut properties that you want the Windows Shell to set at installation run time. |
| <b>ShowProgramFolder</b>   | Displays the specified program folder.                                                                |

## Special Registry-Related Functions

The special registry-related functions are designed to make it easier for script writers to set up the minimum required registry keys and values. The special registry-related functions work only with the per application paths key, the application uninstallation key, or the application information key, as shown below. Refer to the individual function descriptions for more details.

### Per Application Paths Key

<root key>\Software\Microsoft\Windows\CurrentVersion\App Paths\<per application paths key>

This key is referred to as the per application paths key, or App Paths key. The per application paths key stores path information enabling Windows to find your application's executable files. The root key is HKEY\_CURRENT\_USER if the **ALLUSERS** system variable is FALSE or you have called ProgDefGroupType(PERSONAL), or HKEY\_LOCAL\_MACHINE otherwise.

**Table 29** ▪ Per Application Paths Key

| Function                      | Description                                                                                                                                                                                                                                                                                                          |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CreateInstallationInfo</b> | Uses the name of the application executable file to prepare for the creation of the per application paths key. The key is not created until RegDBSetItem is called (see below).<br><br>If you use an event-based script, the CreateInstallationInfo function is called by the default OnMoveData event handler code. |
| <b>RegDBDeleteItem</b>        | Deletes the per application paths key and the value of [Path] or of [DefaultPath] under that key.                                                                                                                                                                                                                    |

**Table 29** ▪ Per Application Paths Key (cont.)

| Function            | Description                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>RegDBGetItem</b> | Retrieves the value of [Path] or of [DefaultPath] under the per applications path key.                                     |
| <b>RegDBSetItem</b> | Results in the creation of the per application paths key, and sets the value of [Path] or of [DefaultPath] under that key. |

## Application Uninstallation Key

<rootkey>\Software\Microsoft\Windows\CurrentVersion\Uninstall\<INSTANCE\_GUID>

This key is referred to as the application uninstallation key. The application uninstallation key stores information enabling uninstallation functionality. The root key is HKEY\_CURRENT\_USER if the **ALLUSERS** system variable is FALSE or you have called ProgDefGroupType(PERSONAL), or HKEY\_LOCAL\_MACHINE otherwise.

**Table 30** ▪ Application Uninstallation Key

| Function                | Description                                                                                                                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaintenanceStart</b> | Creates the application uninstallation key and sets the [UninstallString], [DisplayName] (the name displayed in Add or Remove Programs), and [LogFile] values under that key.<br><br>In an event-based script, MaintenanceStart is called in the default OnMoveData event handler code. |
| <b>RegDBDeleteItem</b>  | Deletes the value of [DisplayName] (the name displayed in Add or Remove Programs) under the application uninstallation key.                                                                                                                                                             |
| <b>RegDBGetItem</b>     | Retrieves the value of [DisplayName] under the application uninstallation key.                                                                                                                                                                                                          |
| <b>RegDBSetItem</b>     | Sets the value of [DisplayName] (the name displayed in Add or Remove Programs) under the application uninstallation key.<br><br>This value is also set by MaintenanceStart (which, if you use an event-based script, is called in the default OnMoveData event handler code).           |

## Application Information Key

<root key>\Software\<company key>\<product key>\<version key>

This key is referred to as the application information key. Your installation should create an application information key for each application it installs. The application information key stores information about the application. The root key is HKEY\_CURRENT\_USER if the **ALLUSERS** system variable is FALSE or you have called ProgDefGroupType(PERSONAL), or HKEY\_LOCAL\_MACHINE otherwise.

**Table 31** ▪ Application Information Key

| Function                      | Description                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CreateInstallationInfo</b> | <p>Uses the company name, product name, and product version number to create the application information key. No values are set under the key until you call the RegDBSetAppInfo function (see below).</p> <p>If you use an event-based script, the CreateInstallationInfo function is called by the default OnMoveData event handler code.</p> |
| <b>RegDBGetAppInfo</b>        | Retrieves a value from under the application information key.                                                                                                                                                                                                                                                                                   |
| <b>RegDBSetAppInfo</b>        | Sets a value under the application information key.                                                                                                                                                                                                                                                                                             |

## SQL Functions

The SQL functions enable you to perform tasks such as connect to a catalog, create SQL-related dialogs, and obtain SQL run-time errors.

**Tip** ▪ For information on SQL support and SQL-related InstallScript functions, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

**Table 32** ▪ SQL Functions

| Function                 | Project Type                           | Description                                                                                                                                                                                                                                                                       |
|--------------------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SQLBrowse</b>         | InstallScript,<br>InstallScript<br>MSI | <p>Creates a dialog that enables the end user to bring up a list of all SQL Servers available on the network.</p> <p><b>SQLBrowse2</b> supersedes this function.</p>                                                                                                              |
| <b>SQLBrowse2</b>        | InstallScript,<br>InstallScript<br>MSI | Creates a dialog that lets an end user display a list of all database servers that are available on the network for the database technologies specified for a connection.                                                                                                         |
| <b>SQLDatabaseBrowse</b> | InstallScript,<br>InstallScript<br>MSI | <p>Creates a dialog that lets the end user display a list of all database catalogs available on the specified database server. This function calls <b>SQLRTGetDatabases</b>, which uses SQLRT.d11 for InstallScript projects and ISSQLSRV.d11 for InstallScript MSI projects.</p> |

**Table 32** ■ SQL Functions (cont.)

| Function                            | Project Type  | Description                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SQLRTComponentInstall</b>        | InstallScript | Executes the SQL script that is associated with the specified component if the script is scheduled to run during installation.                                                                                                                                                                                                                        |
| <b>SQLRTComponentUninstall</b>      | InstallScript | Executes the SQL script that is associated with the specified component if the script is scheduled to run during uninstallation.                                                                                                                                                                                                                      |
| <b>SQLRTConnect</b>                 | InstallScript | Establishes a connection using the specified credential.<br><br><b>SQLRTConnect2</b> supersedes this function.                                                                                                                                                                                                                                        |
| <b>SQLRTConnect2</b>                | InstallScript | Establishes a connection. This function must be called before file transfer if the connection is to be used to run scripts during installation.<br><b>SQLRTConnect2</b> returns the database server name when it fails to establish the connection. It uses SQLRT.dll so it can be called only after <b>SQLRTInitialize2</b> has already been called. |
| <b>SQLRTConnectDB</b>               | InstallScript | Establishes a connection to a specific catalog.                                                                                                                                                                                                                                                                                                       |
| <b>SQLRTDoRollbackAll</b>           | InstallScript | Executes all of SQL scripts scheduled to run during rollback.                                                                                                                                                                                                                                                                                         |
| <b>SQLRTGetBatchList</b>            | InstallScript | Returns the list of components that are associated with SQL scripts that need to be run when batch mode is enabled.<br><br>For details about batch mode, see <a href="#">Specifying the Order for Running Multiple SQL Scripts That Are Associated with a Connection</a> .                                                                            |
| <b>SQLRTGetBatchMode</b>            | InstallScript | Returns whether batch mode is enabled or disabled.                                                                                                                                                                                                                                                                                                    |
| <b>SQLRTGetBrowseOption</b>         | InstallScript | Returns the current value of the browse option for the SQL Server browse combo box and list box controls, which can display local servers, remote servers, server aliases, or a combination of these types.                                                                                                                                           |
| <b>SQLRTGetComponentScriptError</b> | InstallScript | Retrieves the last error while executing a SQL script that is associated with the component.<br><br><b>SQLRTGetComponentScriptError2</b> supersedes this function.                                                                                                                                                                                    |

**Table 32** ■ SQL Functions (cont.)

| Function                                | Project Type                           | Description                                                                                                                                                                                                                                                 |
|-----------------------------------------|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SQLRTGetComponentScriptError2</b>    | InstallScript                          | Retrieves the last error while executing a SQL script that is associated with the component.<br><br>This function takes several parameters (szScriptName, szTechnology, szServer, and szDB) that the <b>SQLRTGetComponentScriptError</b> function does not. |
| <b>SQLRTGetConnectionAuthentication</b> | InstallScript,<br>InstallScript<br>MSI | Gets the default SQL Server connection authentication type.                                                                                                                                                                                                 |
| <b>SQLRTGetConnectionInfo</b>           | InstallScript,<br>InstallScript<br>MSI | Retrieves strings containing the connection information (the default server, database, default user name, and default password).                                                                                                                            |
| <b>SQLRTGetConnections</b>              | InstallScript,<br>InstallScript<br>MSI | Retrieves a string list of connections that are present in the settings file.                                                                                                                                                                               |
| <b>SQLRTGetDatabases</b>                | InstallScript,<br>InstallScript<br>MSI | Returns a list of database catalogs that are available on the specified database server.                                                                                                                                                                    |
| <b>SQLRTGetErrorMessage</b>             | InstallScript                          | Returns the descriptive message of the last error encountered by the SQL run time when a connection is being opened.                                                                                                                                        |
| <b>SQLRTGetLastError</b>                | InstallScript                          | Returns the text of the last error encountered by the SQL run time.<br><br><b>SQLRTGetLastError2</b> supersedes this function.                                                                                                                              |
| <b>SQLRTGetLastError2</b>               | InstallScript                          | Returns detailed information about the last error encountered by the SQL run time and loads the proper SQL error message.                                                                                                                                   |
| <b>SQLRTGetScriptErrorMessage</b>       | InstallScript                          | Returns the descriptive message of the last error encountered by the SQL run time when a SQL script is executing.                                                                                                                                           |
| <b>SQLRTGetServers</b>                  | InstallScript,<br>InstallScript<br>MSI | Returns a list of database servers on the network for all database technologies included in the installation.<br><br><b>SQLRTGetServers2</b> supersedes this function.                                                                                      |

**Table 32** ■ SQL Functions (cont.)

| Function                                | Project Type                           | Description                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SQLRTGetServers2</b>                 | InstallScript,<br>InstallScript<br>MSI | Returns a list of database servers for the database technologies that are specified for a connection. When szConnection is empty, this function behaves as <b>SQLRTGetServers</b> .                                                                                                                                    |
| <b>SQLRTInitialize</b>                  | InstallScript                          | Loads the SQLRT.d11 and initializes it using the settings file. This function must be the first function called in SQLRT.<br><br><b>SQLRTInitialize2</b> supersedes this function.                                                                                                                                     |
| <b>SQLRTInitialize2</b>                 | InstallScript,<br>InstallScript<br>MSI | Loads the SQLRT.d11 file for InstallScript projects and the ISSQLSRV.d11 file for InstallScript MSI projects, and it uses the settings file to initialize the .dll file.<br><br>This function must be the first function called in SQLRT or ISSQLSRV.                                                                  |
| <b>SQLRTPutConnectionAuthentication</b> | InstallScript,<br>InstallScript<br>MSI | Sets the default SQL Server connection authentication type.                                                                                                                                                                                                                                                            |
| <b>SQLRTPutConnectionInfo</b>           | InstallScript,<br>InstallScript<br>MSI | Sets the connection information (the default server, default user name, and default password) so that it is available in the future. This is useful in situations when you need to recall what a user previously entered, like use of the Back button.<br><br><b>SQLRTPutConnectionInfo2</b> supersedes this function. |
| <b>SQLRTPutConnectionInfo2</b>          | InstallScript,<br>InstallScript<br>MSI | Sets the connection information (the default server, default database catalog, default user name, and default password) so that it is available in the future. This is useful in situations when you need to recall what an end user previously entered, like use of the Back button.                                  |
| <b>SQLRTServerValidate</b>              | InstallScript<br>MSI                   | Tests connections specified in the installation.                                                                                                                                                                                                                                                                       |
| <b>SQLRTSetBrowseOption</b>             | InstallScript                          | Specifies whether the SQL Server browse combo box and list box controls should show local servers, remote servers, server aliases, or a combination of these types.                                                                                                                                                    |

**Table 32** ■ SQL Functions (cont.)

| Function                     | Project Type                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SQLRTTestConnection</b>   | InstallScript<br>MSI                   | Tests all of the connections specified in the installation using the specified credential.<br><br><b>SQLRTTestConnection2</b> supersedes this function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SQLRTTestConnection2</b>  | InstallScript<br>MSI                   | Establishes a connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SQLServerLogin</b>        | InstallScript,<br>InstallScript<br>MSI | Creates a dialog that is used by the script to specify SQL login credentials. These credentials include the login ID and password.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SQLServerSelect</b>       | InstallScript,<br>InstallScript<br>MSI | Creates a dialog to specify a server to target.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SQLServerSelectLogin</b>  | InstallScript,<br>InstallScript<br>MSI | Creates a login dialog that enables the targeted end user to specify which SQL Server should to be used for the current connection, as well as which login credential should be used. The dialog displays a combo box that contains a list of SQL Servers accessed through DSNs. The end user can type a server name in the combo box or click the Browse button next to the combo box; clicking this button displays a list of all SQL Servers that are available on the network.<br><br><b>SQLServerSelectLogin2</b> supersedes this function.                                                                                                                                                                                                                     |
| <b>SQLServerSelectLogin2</b> | InstallScript,<br>InstallScript<br>MSI | Creates a login dialog that is used by the default script. It lets the targeted end user specify which SQL Server should be used for the current connection, as well as which login credential should be used. The dialog displays a combo box that contains a list of SQL Servers accessed through DSNs. The end user can type a server name in the combo box or click the Browse button next to the Server Name combo box; clicking this button displays a list of all SQL Servers that are available on the network.<br><br>This function also optionally shows the connection name that is associated with the connection information. In addition, it optionally enables end users to specify which database catalog should be used for the current connection. |

**Table 32** ▪ SQL Functions (cont.)

| Function                      | Project Type                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SQLServerSelectLoginEx</b> | InstallScript,<br>InstallScript<br>MSI | <p>Creates a login dialog that is used by the default script. It lets the targeted end user specify which SQL Server should be used for the current connection, as well as which login credential should be used. The dialog displays a combo box that contains a list of SQL Servers accessed through DSNs. The end user can type a server name in the combo box or click the Browse button next to the Server Name combo box; clicking this button displays a list of all SQL Servers that are available on the network.</p> <p>This function also shows the connection name that is associated with the connection information.</p> <p><b>SQLServerSelectLogin2</b> supersedes this function.</p> |

## String Functions

The string functions provide the ability to manipulate string variables and literals. String functions behave similarly to the standard C language functions. The return values also follow the C language convention.

**Table 33** ▪ String Functions

| Function                             | Description                                                                                                                                                                                                        |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CopyBytes</b>                     | Copies a specified number of bytes from one string to another.                                                                                                                                                     |
| <b>GetCArrayFromISArray</b>          | Returns a pointer to an array of pointers that point to the actual data of the specified array. This function does not allocate any additional memory, but it returns a pointer to the data in the existing array. |
| <b>GetCharArrayFromISStringArray</b> | Returns a pointer to an array of pointers to ANSI character strings that corresponds to the wide character strings that are contained in the specified array.                                                      |
| <b>GetDir</b>                        | Deletes the drive designation from a path or fully qualified file name.                                                                                                                                            |
| <b>GetDisk</b>                       | Retrieves the disk drive designation from a path or fully qualified file name.                                                                                                                                     |
| <b>NumToStr</b>                      | Converts a number to a string.                                                                                                                                                                                     |
| <b>ParsePath</b>                     | Retrieves the drive, path, file name, or extension from a path.                                                                                                                                                    |

**Table 33** ■ String Functions (cont.)

| Function                  | Description                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>StrAddLastSlash</b>    | Adds a trailing backslash to a path specification if it does not already have one.                                                                                                                                                       |
| <b>StrCompare</b>         | Compares one string to another.                                                                                                                                                                                                          |
| <b>StrConvertSizeUnit</b> | Returns the appropriate display string for the InstallScript size unit constant that is specified.                                                                                                                                       |
| <b>StrFind</b>            | Finds a string in another string.                                                                                                                                                                                                        |
| <b>StrFindEx</b>          | Determines whether the string passed in the parameter <code>szFindMe</code> is found within the string passed in the parameter <code>szString</code> ; the function begins its search at the location specified by <code>nStart</code> . |
| <b>StrGetTokens</b>       | Gets a token from a string based on specified delimiters.                                                                                                                                                                                |
| <b>StrLength</b>          | Like <b>StrLengthChars</b> , returns the number of characters in a given string variable (that is, the number of code units in the UTF-16-encoded string) up to the first null character.                                                |
| <b>StrLengthChars</b>     | Like <b>StrLength</b> , returns the number of characters in a given string variable (that is, the number of code units in the UTF-16-encoded string) up to the first null character.                                                     |
| <b>StrPutTokens</b>       | Extracts list items from a specified string list and places them into the string that is specified by <code>svString</code> .                                                                                                            |
| <b>StrRemoveLastSlash</b> | Removes the last backslash in a path string.                                                                                                                                                                                             |
| <b>StrReplace</b>         | Searches <code>svResult</code> , beginning at the location specified by <code>nStart</code> , and replaces all found instances of <code>szFind</code> with <code>szReplace</code> .                                                      |
| <b>StrSub</b>             | Returns a substring from a string.                                                                                                                                                                                                       |
| <b>STRTOCHAR</b>          | Returns the first character of a string as data of type <code>CHAR</code> .                                                                                                                                                              |
| <b>StrToLower</b>         | Converts all alphabetic characters in string to lowercase.                                                                                                                                                                               |
| <b>StrToNum</b>           | Converts a string to a number.                                                                                                                                                                                                           |
| <b>StrToNumHex</b>        | Converts a string to a number—for example, <code>0x1A</code> to <code>26</code> .                                                                                                                                                        |
| <b>StrToUpper</b>         | Converts all alphabetic characters in string to uppercase.                                                                                                                                                                               |
| <b>StrTrim</b>            | Removes the leading and trailing spaces and tabs from a string.                                                                                                                                                                          |

# Suite/Advanced UI and Advanced UI Interaction Functions

**Project** ▪ This information applies to the following project types:

- InstallScript
- Suite/Advanced UI

**Note** ▪ All of these functions are available for InstallScript installations that may be included as InstallScript packages in an Advanced UI or Suite/Advanced UI installation. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

Furthermore, all of these functions except for **FeatureConfigureFeaturesFromSuite** and **SuiteReportError** are available for InstallScript actions that are included in Suite/Advanced UI installations. For more information, see [Working with an Action that Runs InstallScript Code in a Suite/Advanced UI Installation](#).

The **FeatureConfigureFeaturesFromSuite** is also available in the following scenarios; however, the other Advanced UI or Suite/Advanced UI functions return an error:

- The function is called in an InstallScript installation that is launched directly (that is, not from an Advanced UI or Suite/Advanced UI installation).
- The function is called in an InstallScript installation that is included in an Advanced UI or Suite/Advanced UI installation as an executable package.

InstallScript includes the following functions for interacting with an Advanced UI or Suite/Advanced UI installation that contains an InstallScript package. These functions (with the exception of **FeatureConfigureFeaturesFromSuite**) are also available for interacting with the running Suite/Advanced UI installation through an InstallScript action.

**Table 34** ▪ Suite/Advanced UI and Advanced UI Interaction Functions

| Function                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FeatureConfigureFeaturesFromSuite</b> | Sets feature states for the current InstallScript package that is running in an Advanced UI or Suite/Advanced UI installation based on the values of the Advanced UI or Suite/Advanced UI properties <b>ISFeatureInstall</b> and <b>ISFeatureRemove</b> . The function is called by the default code in the OnSuiteInstallBefore event (for an install operation) and OnSuiteMaintBefore event (for a modify operation). |
| <b>SuiteFormatString</b>                 | Resolves Advanced UI or Suite/Advanced UI properties in a string with values from the Advanced UI or Suite/Advanced UI installation.                                                                                                                                                                                                                                                                                     |
| <b>SuiteGetProperty</b>                  | Retrieves the value of an Advanced UI or Suite/Advanced UI property from the Advanced UI or Suite/Advanced UI installation.                                                                                                                                                                                                                                                                                              |
| <b>SuiteLogInfo</b>                      | Logs information about the InstallScript package or action that is running in an Advanced UI or Suite/Advanced UI installation to the Advanced UI or Suite/Advanced UI debug log.                                                                                                                                                                                                                                        |

**Table 34** • Suite/Advanced UI and Advanced UI Interaction Functions (cont.)

| Function                  | Description                                                                                                                                                                                                    |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SuiteReportError</b>   | Displays a message box in the Advanced UI or Suite/Advanced UI user interface to report an error that occurred as the Advanced UI or Suite/Advanced UI installation ran the InstallScript package.             |
| <b>SuiteResolveString</b> | Replaces an Advanced UI or Suite/Advanced UI string identifier with its corresponding string value in the InstallScript package or action that is running in an Advanced UI or Suite/Advanced UI installation. |
| <b>SuiteSetProperty</b>   | Sets the value of an Advanced UI or Suite/Advanced UI property in the Advanced UI or Suite/Advanced UI installation.                                                                                           |

## Text Substitutions

**Project** • This information applies to InstallScript projects.

Text substitution consists of associating a string with another string—for example, associating "<MYTEXTSUB>" with "My Text Sub Value"—and of replacing the former string with the latter in other strings—for example, changing "This string demonstrates text substitution <MYTEXTSUB>" to "This string demonstrates text substitution My Text Sub Value". A text-substitution association can be either global—that is, applying to the scripts of the main installation and any included objects—or local—that is, applying only to the script file in which it occurs, any script files that are included in that script by using the #include preprocessor directive, and any script files in which that script is included. A local text-substitution association that is defined in an object script applies only to that object, not to the main installation or any other objects that are included in the installation; a local text-substitution association that is defined in the main installation script applies only to the main installation, not to any objects that are included in the installation.

A text-substitution association can be embedded in another text-substitution association; for example, "<MYTEXTSUB1>" can be associated with "My Text Sub 1 Value" and "<MYTEXTSUB2>" with "Text Sub <MYTEXTSUB1> Embedded".

InstallScript includes the following functions for using text substitutions:

**Table 35** • Text Substitutions Functions

| Function                   | Description                                                                          |
|----------------------------|--------------------------------------------------------------------------------------|
| <b>TextSubGetValue</b>     | Retrieves the text-substitution string that is associated with the specified string. |
| <b>TextSubParseTextSub</b> | Locates the first text substitution in the specified string.                         |
| <b>TextSubSetValue</b>     | Creates a text-substitution association between the specified strings.               |
| <b>TextSubSubstitute</b>   | Performs text substitution on the specified string variable.                         |

# Uninstallation Functions

The following functions perform services required for the uninstallation and/or maintenance setup of an installed application.

**Table 36** • Uninstallation Functions

| Function                   | Description                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>FeatureGetTotalCost</b> | Determines the total space required for the feature installations and uninstallations that have been specified. |
| <b>FeatureTransferData</b> | Performs the feature installations and uninstallations that have been specified.                                |
| <b>InstallationInfo</b>    | Creates registry keys based on a company name, product name, and product version number.                        |
| <b>RegDBGetItem</b>        | Retrieves values under the per application paths key or the application uninstallation key.                     |
| <b>RegDBSetItem</b>        | Assign values under the per application paths key or the application uninstallation key.                        |

# User Interface Functions

User interface functions allow you to customize certain error messages and titles of error boxes. However, several internal error messages that may be encountered during the development of the setup cannot be modified using user interface functions.

**Table 37** • Visual Interface Functions

| Function           | Description                                                                                |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Disable</b>     | Disables the display of a user interface object.                                           |
| <b>Enable</b>      | Enables the display of a user interface object.                                            |
| <b>FindWindow</b>  | Retrieves the handle to a window.                                                          |
| <b>PlaceBitmap</b> | Inserts an image into the installation window.                                             |
| <b>PlaceWindow</b> | Sets the position of user interface objects.                                               |
| <b>PlayMMedia</b>  | Plays an Adobe Flash application file (.swf), an AVI file, or a sound file (MIDI or WAVE). |
| <b>RGB</b>         | Returns a custom color value based on the specified red, green and blue values.            |

**Table 37** ▪ Visual Interface Functions (cont.)

| Function                | Description                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SetColor</b>         | Changes the color of various user-interface elements.                                                                                     |
| <b>SetDialogTitle</b>   | Creates custom dialog titles.                                                                                                             |
| <b>SetDisplayEffect</b> | Sets the display effect for bitmap and metafile images.                                                                                   |
| <b>SetErrorMsg</b>      | When a disk error occurs, this function sets the corresponding error message that is displayed by the <b>EnterDiskError</b> function.     |
| <b>SetErrorTitle</b>    | When a disk error occurs, this function sets the title bar for the error message that is displayed by the <b>EnterDiskError</b> function. |
| <b>SetFont</b>          | Sets the font type and style.                                                                                                             |
| <b>SetStatusWindow</b>  | Sets the text for the status window and sets the initial percentage completed value that is displayed in the progress indicator.          |
| <b>SetTitle</b>         | Sets the text and color of the title in the main window.                                                                                  |
| <b>SizeWindow</b>       | Specifies the size of most user interface objects.                                                                                        |
| <b>StatusUpdate</b>     | Sets the percent complete to display in the progress indicator after the next file transfer operation.                                    |

## Version-Checking Functions

The following functions enable you to access version information that is present on Windows-based systems. In order to use the functions, you need to know background information about version resources. Review Microsoft Windows documentation to gain a better understanding of the version resource.

**Table 38** ▪ Version-Checking Functions

| Function                         | Description                                                             |
|----------------------------------|-------------------------------------------------------------------------|
| <b>VerCompare</b>                | Compares two strings containing version information.                    |
| <b>VerFindFileVersion</b>        | Searches for the specified file and retrieves its version and location. |
| <b>VerGetFileLanguages</b>       | Retrieves the list of languages that a specified file supports.         |
| <b>VerGetFileVersion</b>         | Retrieves the version of a specified file.                              |
| <b>VerProductCompareVersions</b> | Compares product versions.                                              |

**Table 38** • Version-Checking Functions (cont.)

| Function                             | Description                                                                                                                                   |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VerProductGetInstalledVersion</b> | Returns the string equivalent of the data in the Version value of the application uninstallation registry key if that data is a packed DWORD. |
| <b>VerProductIsVersionSupported</b>  | Checks whether a version string is a supported version.                                                                                       |
| <b>VerProductNumToStr</b>            | Returns a string for a specified packed DWORD version.                                                                                        |
| <b>VerProductStrToNum</b>            | Returns a packed DWORD version for a specified string.                                                                                        |
| <b>VerProductVerFromVerParts</b>     | Retrieves the packed DWORD that corresponds to the version parts that are specified by nVersionMajor, nVersionMinor, and nVersionBuild.       |
| <b>VerProductVerPartsFromVer</b>     | Retrieves as separate numeric values the version parts of a specified packed DWORD.                                                           |
| <b>VerSearchAndUpdateFile</b>        | Replaces an existing file with a more recent version. If the specified file does not exist, the more recent version is installed.             |
| <b>VerUpdateFile</b>                 | Replaces an existing file with a more recent version. If the specified file does not exist, the more recent version is installed.             |

## Windows Installer Functions

Windows Installer functions, or APIs, are functions exported by the Windows Installer engine. They enable you to query and temporarily manipulate tables of a running installation.

One common use for adding temporary records to a running database is to populate user-interface elements with data not available until run time. For example, you can use Windows Installer APIs to populate a ListBox control in dialog with a list of mapped network drives, user accounts, directory names, or other data that can be discovered only while an installation is running on a particular target system.

For more information about any Windows Installer function, see the [Windows Installer Help](#).

## Windows Installer API Functions

You can call Windows Installer API functions from the main script and from within an InstallScript custom action. InstallScript supports these Windows Installer API functions:

**Note** • Most Windows Installer API functions take a handle to the currently running database as an argument. For an InstallScript custom action, the database handle is the *HWND* argument passed to the custom action. In an event-handler function, you can use the global variable *ISMSI\_HANDLE*, which stores the handle to the running .msi database.

**Note** - For Windows APIs that require a buffer size and when the size of the value of the buffer size is greater than 1024 characters, a valid buffer size must be specified. For an example of how to write code for this scenario, refer to *Changes in Behavior for Some MSI APIs That Are Called in InstallScript Custom Actions in the “Upgrading Projects from InstallShield 2011 or Earlier” topic.*

**Table 39** - Windows Installer API Functions

|                               |                          |                           |
|-------------------------------|--------------------------|---------------------------|
| MsiApplyPatch                 | MsiGetLanguage           | MsiRecordSetInteger       |
| MsiCloseHandle                | MsiGetLastErrorRecord    | MsiRecordSetStream        |
| MsiCreateTransformSummaryInfo | MsiGetMode               | MsiRecordSetString        |
| MsiDatabaseApplyTransform     | MsiGetProperty           | MsiSequence               |
| MsiDatabaseExport             | MsiGetSourcePath         | MsiSetComponentState      |
| MsiDatabaseGenerateTransform  | MsiGetSummaryInformation | MsiSetFeatureAttributes   |
| MsiDatabaseGetPrimaryKeys     | MsiGetTargetPath         | MsiSetFeatureState        |
| MsiDatabaseImport             | MsiInstallProduct        | MsiSetInstallLevel        |
| MsiDatabaseIsTablePersistent  | MsiOpenDatabase          | MsiSetMode                |
| MsiDatabaseMerge              | MsiOpenPackage           | MsiSetProperty            |
| MsiDatabaseOpenView           | MsiPreviewBillboard      | MsiSetTargetPath          |
| MsiDoAction                   | MsiPreviewDialog         | MsiSummaryInfoGetProperty |
| MsiEnumComponentCosts         | MsiProcessMessage        | MsiSummaryInfoSetProperty |
| MsiEvaluateCondition          | MsiRecordClearData       | MsiVerifyDiskSpace        |
| MsiFormatRecord               | MsiRecordDataSize        | MsiViewClose              |
| MsiGetActiveDatabase          | MsiRecordGetFieldCount   | MsiViewExecute            |
| MsiGetComponentState          | MsiRecordGetInteger      | MsiViewFetch              |
| MsiGetFeatureCost             | MsiRecordGetString       | MsiViewGetColumnInfo      |
| MsiGetFeatureState            | MsiRecordIsNull          | MsiViewGetError           |
| MsiGetFeatureValidStates      | MsiRecordReadStream      |                           |

## Windows Installer API Functions by Category

This section includes the function signatures for the Windows Installer API functions available in InstallScript. See the [Windows Installer Help](#) for information about a function's usage, parameters, return values, and sequencing restrictions.

## MSI Property and Mode Functions

**Table 40** ▪ MSI Property and Mode Functions

| Function                                                                                     | Description                                                                                                                                     |
|----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>prototype</b> INT MsiSetProperty(HWND, BYVAL STRING, BYVAL STRING);                       | Sets the value of a Windows Installer property. Creates the property if it does not exist. (For an example, see Getting or Setting Properties.) |
| <b>prototype</b> INT MsiGetProductInfo(BYVAL STRING, BYVAL STRING, BYVAL STRING, BYREF INT); | Returns product information for published and installed products.                                                                               |
| <b>prototype</b> INT MsiGetProperty(HWND, BYVAL STRING, BYREF STRING, BYREF INT);            | Gets the value of a Windows Installer property. Returns a null string ("") if the property does not exist.                                      |
| <b>prototype</b> INT MsiGetLanguage(HWND);                                                   | Returns the numeric language ID for the running installation.                                                                                   |
| <b>prototype</b> BOOL MsiGetMode(HWND, INT);                                                 | Returns an internal boolean Installer state.                                                                                                    |
| <b>prototype</b> INT MsiSetMode(HWND, INT, BOOL);                                            | Sets an internal boolean Installer state.                                                                                                       |

## Feature and Component Functions

**Table 41** ▪ Feature and Component Functions

| Function                                                                           | Description                                                                         |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>prototype</b> INT MsiGetFeatureState(HWND, BYVAL STRING, BYREF INT, BYREF INT); | Gets the installation state and action state of a feature.                          |
| <b>prototype</b> INT MsiSetFeatureState(HWND, BYVAL STRING, INT);                  | Sets the installation state of a feature.                                           |
| <b>prototype</b> INT MsiSetFeatureAttributes(HWND, BYVAL STRING, INT);             | Sets the attributes for a feature.                                                  |
| <b>prototype</b> INT MsiGetFeatureValidStates(HWND, BYVAL STRING, BYREF INT);      | Returns a set of bit flags representing the valid installation states of a feature. |

**Table 41** • Feature and Component Functions (cont.)

| Function                                                                                        | Description                                                                                               |
|-------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <b>prototype</b> INT<br><b>MsiGetComponentState</b> (HWND, BYVAL STRING, BYREF INT, BYREF INT); | Gets the installation state and action state of a component.                                              |
| <b>prototype</b> INT<br><b>MsiSetComponentState</b> (HWND, BYVAL STRING, INT);                  | Sets the installation state of a component.                                                               |
| <b>prototype</b> INT <b>MsiGetFeatureCost</b> (HWND, BYVAL STRING, INT, INT, BYREF INT);        | Returns the disk cost of a feature (in units of 512 bytes), and optionally its parent and child features. |
| <b>prototype</b> INT <b>MsiSetInstallLevel</b> (HWND, INT);                                     | Sets the install level for the entire product.                                                            |

## Directory Functions

**Table 42** • Directory Functions

| Function                                                                                    | Description                                                                                                                        |
|---------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>prototype</b> INT <b>MsiGetSourcePath</b> (HWND, BYVAL STRING, BYREF STRING, BYREF INT); | Returns the full source path for a directory listed in the Directory table. (The Directory table is exposed in the Direct Editor.) |
| <b>prototype</b> INT <b>MsiGetTargetPath</b> (HWND, BYVAL STRING, BYREF STRING, BYREF INT); | Returns the full target path for a directory listed in the Directory table.                                                        |
| <b>prototype</b> INT <b>MsiSetTargetPath</b> (HWND, BYVAL STRING, BYVAL STRING);            | Sets the full target path for a directory listed in the Directory table.                                                           |
| <b>prototype</b> INT<br><b>MsiVerifyDiskSpace</b> (HWND);                                   | Verifies if sufficient disk space exists for the current installation.                                                             |

## Database Functions

With the exception of **MsiGetActiveDatabase**, the first HWND argument in most of these functions is a handle to a specific database view or record.

**Table 43** • Database Functions

| Function                                                    | Description                                                                 |
|-------------------------------------------------------------|-----------------------------------------------------------------------------|
| <b>prototype</b> INT<br><b>MsiEvaluateCondition</b> (HWND); | Evaluates a conditional expression that contains property names and values. |

Table 43 ■ Database Functions (cont.)

| Function                                                                                       | Description                                                                                                                                                            |
|------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>prototype</b> INT<br><b>MsiGetActiveDatabase(HWND);</b>                                     | Obtains a handle to the running .msi database, which you can use to open database views.                                                                               |
| <b>prototype</b> INT<br><b>MsiDatabaseApplyTransform(HWND, BYVAL STRING, INT);</b>             | Applies a transform to a database. A transform is a way of recording changes to a database without altering the original database.                                     |
| <b>prototype</b> INT <b>MsiDatabaseExport(HWND, BYVAL STRING, BYVAL STRING, BYVAL STRING);</b> | Exports an installer table from an open database to a text archive file.                                                                                               |
| <b>prototype</b> INT<br><b>MsiDatabaseGenerateTransform(HWND, BYVAL STRING, INT, INT);</b>     | Generates a transform file of differences between two databases. A transform is a way of recording changes to a database without altering the original database.       |
| <b>prototype</b> INT<br><b>MsiDatabaseGetPrimaryKeys(HWND, BYVAL STRING, BYREF HWND);</b>      | Returns a record containing the names of all the primary key columns for a specified table. This function returns a handle that should be closed using MsiCloseHandle. |
| <b>prototype</b> INT <b>MsiDatabaseImport(HWND, BYVAL STRING, BYVAL STRING);</b>               | Imports an installer text archive table into an open database.                                                                                                         |
| <b>prototype</b> INT<br><b>MsiDatabaseIsTablePersistent(HWND, BYVAL STRING);</b>               | Returns an enumeration describing the state of a particular table.                                                                                                     |
| <b>prototype</b> INT <b>MsiDatabaseMerge(HWND, HWND, BYVAL STRING);</b>                        | Merges two databases together, allowing duplicate rows.                                                                                                                |
| <b>prototype</b> INT<br><b>MsiDatabaseOpenView(HWND, BYVAL STRING, BYREF INT);</b>             | Prepares a database query, creating a view object.                                                                                                                     |
| <b>prototype</b> INT <b>MsiFormatRecord(HWND, HWND, BYREF STRING, BYREF INT);</b>              | Formats record field data and properties using a format string.                                                                                                        |
| <b>prototype</b> INT <b>MsiViewModify(HWND, INT, HWND);</b>                                    | Modifies a database record. For a running installation, only temporary database changes are allowed.                                                                   |
| <b>prototype</b> INT <b>MsiOpenDatabase(BYVAL STRING, BYVAL STRING, BYREF HWND);</b>           | Opens a database file for data access. This function returns a handle that should be closed using MsiCloseHandle.                                                      |
| <b>prototype</b> INT <b>MsiViewClose(HWND);</b>                                                | Closes an executed database view.                                                                                                                                      |
| <b>prototype</b> INT <b>MsiViewExecute(HWND, HWND);</b>                                        | Executes a SQL query.                                                                                                                                                  |

Table 43 ■ Database Functions (cont.)

| Function                                                                             | Description                                                                                              |
|--------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <b>prototype</b> INT <b>MsiViewFetch</b> (HWND, BYREF HWND);                         | Fetches a record for the current database view.                                                          |
| <b>prototype</b> INT <b>MsiRecordGetString</b> (HWND, INT, BYREF STRING, BYREF INT); | Returns the string stored in a specific field of the specified record.                                   |
| <b>prototype</b> INT <b>MsiRecordSetString</b> (HWND, INT, BYVAL STRING);            | Sets the string stored in a specific field of the specified record.                                      |
| <b>prototype</b> INT <b>MsiRecordReadStream</b> (HWND, INT, CHAR, POINTER);          | Returns the string value of a record field.                                                              |
| <b>prototype</b> INT <b>MsiRecordSetStream</b> (HWND, INT, BYVAL BINARY);            | Sets a record stream field from a file. Stream data cannot be inserted into temporary fields.            |
| <b>prototype</b> INT <b>MsiRecordGetInteger</b> (HWND, INT);                         | Returns the integer stored in a specific field of the specified record.                                  |
| <b>prototype</b> INT <b>MsiRecordSetInteger</b> (HWND, INT, INT);                    | Sets the integer stored in a specific field of the specified record.                                     |
| <b>prototype</b> INT <b>MsiViewGetColumnInfo</b> (HWND, INT, BYREF INT);             | Returns a record containing database column names or definitions.                                        |
| <b>prototype</b> INT <b>MsiRecordGetFieldCount</b> (HWND);                           | Returns the number of fields (columns) in a record.                                                      |
| <b>prototype</b> INT <b>MsiCloseHandle</b> (HWND);                                   | Closes a database, view, or record handle.                                                               |
| <b>prototype</b> <b>MsiCloseAllHandles</b> ( );                                      | Closes all open handles. Provided for diagnostic purposes, and should not be called for general cleanup. |
| <b>prototype</b> INT <b>MsiViewGetError</b> (HWND, BYREF STRING, BYREF INT);         | Returns an error code for an error generated by MsiViewModify.                                           |

## Summary Information Stream Management Functions

**Table 44** • Summary Information Stream Management Functions

| Function                                                                                                                     | Description                                                                                                                                        |
|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>prototype</b><br><b>MsiGetSummaryInformation(HWND, BYVAL STRING, INT, BYREF HWND);</b>                                    | Obtains a handle to summary information data for an installer database. This function returns a handle that should be closed using MsiCloseHandle. |
| <b>prototype INT</b><br><b>MsiSummaryInfoGetProperty(HWND, INT, BYREF INT, BYREF INT, POINTER, BYREF STRING, BYREF INT);</b> | Gets a single property from the summary information.                                                                                               |
| <b>prototype INT</b><br><b>MsiSummaryInfoSetProperty(HWND, INT, INT, INT, POINTER, BYREF STRING);</b>                        | Sets a single summary information property.                                                                                                        |

## Miscellaneous Functions

**Table 45** • Miscellaneous Functions

| Function                                                                              | Description                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>prototype INT MsiApplyPatch(BYVAL STRING, BYVAL STRING, INT, BYVAL STRING);</b>    | For each product listed by the patch package as eligible to receive the patch, the MsiApplyPatch function invokes an installation and sets the PATCH property to the path of the patch package. |
| <b>prototype HWND MsiCreateRecord(INT);</b>                                           | Creates a new record object with the specified number of fields. This function returns a handle that should be closed using MsiCloseHandle.                                                     |
| <b>prototype INT MsiDoAction(HWND, BYVAL STRING);</b>                                 | Executes a built-in action, custom action, or user-interface wizard action.                                                                                                                     |
| <b>prototype INT</b><br><b>MsiEvaluateCondition(HWND, BYVAL STRING);</b>              | Evaluates a conditional expression containing property names and values.                                                                                                                        |
| <b>prototype INT MsiInstallProduct(BYVAL STRING, BYVAL STRING);</b>                   | Installs or uninstalls a product.                                                                                                                                                               |
| <b>prototype INT MsiOpenPackage(BYVAL STRING, BYREF HWND);</b>                        | Opens a package for use with the functions that access the product database. The MsiCloseHandle function must be called with the handle when the handle is no longer needed.                    |
| <b>prototype INT</b><br><b>MsiPreviewBillboard(HWND, BYVAL STRING, BYVAL STRING);</b> | Displays a billboard within a host control in the displayed dialog. Supplying a null billboard name removes any billboard displayed.                                                            |

Table 45 • Miscellaneous Functions (cont.)

| Function                                                                | Description                                                            |
|-------------------------------------------------------------------------|------------------------------------------------------------------------|
| <b>prototype</b> <code>INT MsiPreviewDialog(HWND, BYVAL STRING);</code> | Displays a dialog as modeless and inactive.                            |
| <b>prototype</b> <code>int MsiProcessMessage(HWND, int, HWND);</code>   | Sends an error record to the installer for processing.                 |
| <b>prototype</b> <code>INT MsiSequence(HWND, BYVAL STRING, INT);</code> | Executes another action sequence, as described in the specified table. |

## Windows Installer API Functions Example

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates several Windows API functions that are used
* to access the tables of the .msi database at run time and
* add temporary records.
*
* Note: Before running this script, add a ListBox control to
*       the ReadyToInstall dialog, and associate the control
*       with the property LISTBOXPROP.
*
* This script populates the ListBox control in the ReadyToInstall
* dialog with the current values of every property listed in
* the Property table. The end user's selection for the ListBox
* is stored in LISTBOXPROP.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "ifx.h"

// InstallScript custom action entry point
export prototype PropDisplay(HWND);

function PropDisplay(hInstall)
    HWND hDB, hViewlist, hRecordlist;
    HWND hViewprop, hRecordprop;
    NUMBER nBuffer, r;
    STRING svPropname, svPropvalue;
begin

    hDB = MsiGetActiveDatabase(hInstall);

    // open view into ListBox table
    MsiDatabaseOpenView(hDB,
        "SELECT * FROM `ListBox` WHERE `Property`='LISTBOXPROP'",
        hViewlist);
    MsiViewExecute(hViewlist, NULL);

```

```

// open view into Property table
MsiDatabaseOpenView(hDB,
    "SELECT * FROM `Property`", hViewprop);
MsiViewExecute(hViewprop, NULL);

r = 0;

// for each Property record, add PROPNAME="value" record
// to ListBox table
while (MsiViewFetch(hViewprop, hRecordprop) != ERROR_NO_MORE_ITEMS)

    nBuffer = 256; // set size buffer
    MsiRecordGetString(hRecordprop, 1, svPropname, nBuffer);
    nBuffer = 256; // reset size buffer
    MsiGetProperty(hInstall, svPropname, svPropvalue, nBuffer);

    r = r + 1;

    hRecordlist = MsiCreateRecord(4);

    MsiRecordSetString(hRecordlist, 1, "LISTBOXPROP");
    MsiRecordSetInteger(hRecordlist, 2, r);
    MsiRecordSetString(hRecordlist, 3, svPropname);
    MsiRecordSetString(hRecordlist, 4, svPropname + "=" + svPropvalue);

    // can only temporarily modify running .msi database
    MsiViewModify(hViewlist, MSIMODIFY_INSERT_TEMPORARY, hRecordlist);

endwhile;

MsiViewClose(hViewlist);
MsiViewClose(hViewprop);
end;

```

# Operators

An operator is a symbol that specifies a basic operation to be performed using one or two operands—such as addition. The operands can be constants, variables, or function calls. In the example below, the plus sign ( + ) indicates that the variable to the immediate left and the value to the immediate right should be added.

```
nCounter + 1;
```

## Operator Functionality

Most InstallScript operators correspond to operators in C and behave very much like their counterparts in that language. As in C, the function of some operators, such as + and ^ depends on the data type of the operands. For example, when a plus sign is used with numeric operands, addition is performed. When a plus sign is used with string operands, concatenation is performed.

## Expressions

The combination of operator and operands is called an expression. The example above is a simple expression because it includes only one operator. Complex expressions like the one below specify multiple operations:

```
nPrincipal * nRate - nFee;
```

## Evaluating Complex Expressions

In complex expressions, the order in which operations are performed depends on the order of operator precedence. InstallScript operators follow the same order of precedence as C operators. As with C, you can enclose an expression within parentheses to override the order of precedence.

## Results

Most expressions produce a new value based on the existing value of the operands. For that reasons, expressions are also referred to by the data type of the result they produce. Arithmetic expressions produce a numeric value, Boolean expressions produce TRUE or FALSE. String expressions produce a string.

# Address Operator (&)

The address operator is a unary operator that can be used to obtain the memory address of any variable in your script. The operator itself should precede the variable name, with no intervening space. You can use the address operator to assign the address of a variable to a pointer variable or to pass the address of a variable as an argument in a function call. You can send the address to C programs and operate on them as you would any standard C pointer.

In the example below, the address of a data structure is assigned to a pointer variable:

```
typedef DIMENSIONS
begin
    SHORT sLength;
    SHORT sWidth;
end;

DIMENSIONS rectangle;
DIMENSIONS POINTER pointerObject;
```

```
begin
    pointerObject = &rectangle;

    // . .

end;
```

**Caution** ▪ If you use the address operator with a local variable, be aware that the local variable exists only during the life of the function in which it is declared. After the function returns, the address of the local variable will no longer be valid.

## Append to Path Operator (^)

Use the append to path ( ^ ) operator when you are combining two paths or a path and a file name. The operator automatically checks to see if you have added the proper number of backslashes when appending a file name or a subdirectory to a path.

If you type:

```
szStringVar = "C:\\MyPath\\" ^ "YourPath\\FileName";
```

the output from szStringVar is:

```
C:\\MyPath\\YourPath\\FileName
```

If you forgot to add the backslashes after MYPATH, as shown below:

```
szStringVar = "C:\\MyPath" ^ "YourPath\\FileName";
```

the result of the operation is still valid. The InstallScript ^ operator adds the backslashes for you.

**Note** ▪ Do not use the ^ operator to join strings other than paths, such as registry keys. For other types of strings, use the concatenate operator (+).

## Arithmetic Operators (+, -, \*, /)

Arithmetic operators perform mathematical operations such as addition and subtraction with operands. There are two types of mathematical operators, unary and binary. Unary operators perform an action with a single operand. Binary operators perform actions with two operands. In complex expressions—those that include two or more operations—the order of evaluation depends on operator precedence.

### Arithmetic Operator Precedence

When the InstallScript compiler encounters a complex expression—one that includes two or more simple expressions—it evaluates those expressions one at a time.

## Operator Precedence

The order in which expressions are evaluated is determined by operator precedence. The compiler evaluates arithmetic operators using the same order of precedence that the C language uses:

1. Negative ( - ) unary.
2. Multiplication and division.
3. Addition and subtraction.
4. Left to Right Processing

If an expression contains two or more operators with the same precedence level, the operator to the left is processed first. For example, in the expression  $15 / 3 * 7$ , the InstallScript compiler first performs the division ( $15 / 3$ ), then multiplies the result by 7.

## Using Parentheses to Affect Processing

When a lower order precedence operation must be performed first, it should be surrounded by parentheses. For example, if the addition must be performed before the multiplication in the expression  $30 / 3 + 7$ , place parentheses around  $3 + 7$ . The parentheses in the expression  $30 / (3 + 7)$  cause the compiler to add 3 and 7 first, yielding 10, and then divide 30 by 10 for a final result of 3.

### Nested Parentheses

You can nest parentheses within an expression. InstallShield allocates 20 temporary locations for calculating nested expressions. Therefore, you can nest 19 levels of operations within parentheses. The InstallShield Script Compiler performs the innermost operation first and works its way outward.

### Example Expression

For example, in the expression  $36 - (3 * (2 + 6 - 4))$ , the InstallScript compiler first performs the operation  $2 + 6$ , which yields 8, then subtracts 4 from 8, yielding 4, then multiplies 3 by 4, yielding 12, and finally subtracts 12 from 36, yielding 24.

**Note** ▪ Within the inner parentheses, InstallShield performed the addition operation first because it was the further left of two operators with equal precedence.

## Binary Arithmetic Operators

The InstallScript compiler recognizes the binary arithmetic operators listed in the following table.

**Table 1** ▪ Binary Arithmetic Operators

| Symbol | Operation   | Example | Description                                          |
|--------|-------------|---------|------------------------------------------------------|
| +      | Addition    | $x + y$ | Adds two operands.                                   |
| -      | Subtraction | $x - y$ | Subtracts the second operand from the first operand. |

**Table 1** • Binary Arithmetic Operators (cont.)

| Symbol | Operation      | Example | Description                                                                                                                                                                                        |
|--------|----------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *      | Multiplication | x * y   | Multiplies two operands.                                                                                                                                                                           |
| /      | Division       | x / y   | Divides the first operand by the second operand.<br><br>Because InstallShield does not have floating-point data types, the fractional part of the answer is dropped. For example, 5/2 = 2.5 --> 2. |
| %      | Modulus        | 19 % 5  | Divides the first operand by the second operand and returns the remainder. For example, nResult = 19 % 5; results in nResult = 4.                                                                  |

**Tip** • You should include a space both before and after an arithmetic operator to make your script more readable and to maintain a consistent appearance.

## Unary Arithmetic Operators

Unary operators are arithmetic operators that perform an action on a single operand. The InstallScript compiler recognizes two unary operators, negative ( - ) and positive ( + ).

### Negative

The negative unary operator reverses the sign of an expression from positive to negative or from negative to positive. The net result of using the negative unary operator before an expression is the same as multiplying the expression by -1.

### Positive

The positive unary operator has the same net result on an expression as multiplying that expression by 1. It does not change the sign of a negative number to positive.

## Assignment Operator

Use the assignment operator ( = ) to copy a constant, literal, variable, expression result, or function result to a variable of the same type, as shown in the example code fragment below:

```

STRING szName;
LONG nValue;
BOOL bDone;
HWND hInstance;
INT iStyle;
LIST LISTINFO;

```

```

szName = "InstallShield";
nValue = 15;
bDone = FALSE;
hInstance = 0;
iStyle = DLG_MSG_STANDARD|DLG_CENTERED;

```

```
LISTINFO = ListCreate(StringList);
```

InstallShield automatically sizes string variables that are declared without an explicit length, as in the example above. By default, InstallShield autosizes the string variable to 256 bytes. If you assign to that variable a string longer than 256 bytes (including the null terminator), InstallShield increases the amount of memory reserved for that string variable.

If you declare a string variable with an explicit length, you must make it long enough to receive the string you assign to it. In the example below, the string literal contains 51 characters. Therefore, both `szStringVarA` and `szStringVarB` must have a declared length of at least 52, which is just large enough to accommodate the string itself and the null terminator that is added automatically to the end of the string.

```

STRING szStringVarA[52], szStringVarB[52];
szStringVarA = "This is a sample string that is 51 characters long.";
szStringVarB = szStringVarA;

```

**Caution** ▪ Unlike C++, InstallScript does not support multiple assignment operations in a single statement. In InstallScript, the statement `a = b = c` is equivalent to the C++ statement `a = b == c`. That is, the first operator is interpreted as an assignment operator; the second is interpreted as a relational operator. If `b` is equal to `c`, the value 1 (TRUE) is assigned to `a`; if `b` is not equal to `c`, the value 0 (FALSE) is assigned to `a`.

## Bit Operators (&, |, ^, ~, <<, >>)

Bit, or bitwise, operators allow you to manipulate individual bits in a numeric variable. In order to use the operators effectively, you need to be familiar with binary notation. This topic gives you an overview of binary operators, but it does not try to teach you binary notation.

Bit operators work like logical operators, with one exception: logical operators work with expressions, bit operators work with bits. The InstallScript compiler recognizes the bitwise operators listed in the table below:

**Table 2** ▪ Bit Operators

| Symbol | Operator | Explanation                                                                                                               |
|--------|----------|---------------------------------------------------------------------------------------------------------------------------|
| &      | BitAND   | BitAND sets a bit in the result to 1 (TRUE) only if the bits in both operands are 1s; otherwise, the result is 0 (FALSE). |
|        | BitOR    | Bit inclusive OR sets a bit in the result to 0 only if the bits in the operands are 0; otherwise, the result is 1.        |

**Table 2** ▪ Bit Operators (cont.)

| Symbol                | Operator    | Explanation                                                                                                                                                                                          |
|-----------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>^</code>        | BitXOR      | Bit exclusive OR sets a bit in the result to 1 if the corresponding bits in the operands are different (one 1, the other 0). Otherwise, the result is 0.                                             |
| <code>~</code>        | BitNOT      | <p>BitNOT is a unary operator that reverses every bit in the operand, changing every 1 to a 0 and vice versa, as in the following example:</p> <pre>~00001100</pre> <p>The result is 11110011.</p>   |
| <code>&lt;&lt;</code> | Shift left  | <p>Moves bits a specified number of bits to the left. For example, the expression shown below moves bits three spaces to the left:</p> <pre>00001100 &lt;&lt; 3</pre> <p>The result is 01100000.</p> |
| <code>&gt;&gt;</code> | Shift right | <p>Moves bits a specified number of bits to the right. For example, the expression shown below moves bits two spaces to the right:</p> <pre>00001100 &gt;&gt; 2</pre> <p>The result is 00000011.</p> |

Shift operations work the same way in InstallScript that they do in the C language. When you shift by two bits to the right (`>> 2`), the two bit values furthest to the right are lost. The other bit values are shifted to the right two places, and the sign bit is shifted into the empty bits.

You can use shift operations to multiply and divide a value by a power of 2. Left-shifting an integer by *n* has the same effect as multiplying the number by 2 to the power of *n*. Right-shifting an integer by *n* has the same effect as dividing the number by 2 to the power of *n*.

## BYREF Operator

By default, the parameters of a user-defined function are passed by value; that is, a copy of the data specified by each parameter is passed to the function. Because the function operates on a copy, the original data cannot be changed by the function.

**Note** ▪ There is one exception: By default, string variables passed to DLL functions are passed by reference, so the value of the variable can be changed by the function.

When you want a user-defined function to operate directly on a variable it receives in a parameter rather than on a copy of that variable, you must specify the BYREF operator with the parameter type declaration in the function prototype, as shown below:

```
prototype StrInvert( BYREF STRING );
```

The BYREF operator indicates that the parameter is to be passed by reference—that is, the actual variable is to be passed to the function, and any changes made to that variable will be visible to the caller when the function returns. Parameters that are passed by reference are often referred to as variable parameters because they require a variable. Constants and literals cannot be passed by reference.

## Using BYREF With Multiple Parameters

When a user-defined function has more than one parameter, the BYREF operator must be specified with each variable parameter. In the example below, the first and third parameters are passed by reference and the second parameter is passed by value:

```
prototype StrChangeChar( BYREF STRING, CHAR, BYREF BOOL);
```

## Limitations

User-defined structure members cannot be passed by reference. Attempting to do so results in a compiler error. Instead, you must pass a pointer to the entire structure by reference and then use the structure pointer operator (->) to access or modify the data elements of the structure.

An autosized string variable that is passed by reference to a function will not be autosized within the called function. If the function attempts to assign a value whose length is greater than the current size of that parameter, run-time error 401 occurs. To avoid this error, declare strings with a specific size when they are to be passed by reference to a function.

# BYVAL Operator

The keyword BYVAL can be specified in the parameter specification of a function prototype to indicate a parameter that is passed by value rather than by reference, as in the example below:

```
prototype DisplayString( BYVAL STRING );
```

When a parameter is passed by value, the function receives a copy of the value and any changes it makes to that value are local to the function.

By default, the parameters of a user-defined function are passed by value; so generally it is not necessary to specify this keyword in a function prototype. (There is one exception: by default, string variables passed to DLL functions are passed by reference, so the value of the variable can be changed by the function.)

When you want a user-defined function to operate directly on a variable it receives in a parameter rather than on a copy of that variable, you must specify the BYREF operator.

# Concatenate Operator (+)

Use the concatenate string operator ( + ) to join one string to the end of another. Concatenating two strings results in a new, third string. In the following example, two string constants are concatenated and the resulting string value is assigned to the string variable szThirdString; after the statement has been executed, the value of szThirdString is "First string Second string".

```
szThirdString = "First string " + "Second string";
```

Operands in a concatenation expression may be string literals, string constants, or string variables. In the example below, a string constant and a string literal are concatenated. The resulting string value is assigned to szThirdString.

```
#define FIRST_STRING "This is the first string"
```

```
    STRING szThirdString;
```

```
// . . .
```

```
    szThirdString = FIRST_STRING + "Second string";
```

---

**Caution** ▪ When assigning the result of a concatenation expression to a string variable, you must ensure that the concatenated string is not too long for the string variable to which it is assigned. A statement that assigns a string to a variable of insufficient size produces run-time error 401.

## Indirection Operator (\*)

The indirection operator is a unary operator that can be used to obtain the value stored at the memory location referenced by a pointer variable. The indirection operator must precede the pointer variable name, with no intervening space.

In the following example, nvalue is a number and pnumber is a pointer to a number. The assignment statement is used to copy to nvalue the number being pointed to by pnumber.

```
nvalue = *pnumber;
```

The indirection operator can also be used to pass a value to a function that takes a number value as a parameter, as in the following example:

```
somefunction(*pnumber);
```

The following limitations apply to the indirection operator:

- The indirection operator can be used with number pointers only.
- The indirection operator cannot be used to assign a value to a memory location.
- The indirection operator cannot be used as an argument to a function whose parameter has been defined with the BYREF operator.
- The indirection operator cannot be used to declare a pointer.
- The indirection operator cannot be used to declare a variable parameter in a function declaration.

## Logical Operators (&&, ||, !)

Logical operators allow you to ask more than one relational question at the same time. For example, using a logical operator you can ask if y is greater than 7 and szFilePath contains "C:\\Program Files\\Company Name". Logical operators return either a TRUE (1) or FALSE (0) value. Like relational operators, they are used most often in if and while statements.

The InstallScript compiler recognizes the logical operators listed in the table below:

**Table 3** • Logical Operators

| Symbol | Operation | Example      | Description                                                            |
|--------|-----------|--------------|------------------------------------------------------------------------|
| &&     | AND       | exp1 && exp2 | True only if both exp1 and exp2 are true; otherwise, false.            |
|        | OR        | exp1    exp2 | True if either exp1 or exp2 is true; false (0) only if both are false. |
| !      | NOT       | !exp1        | False if exp1 is true; true if exp1 is false.                          |

Logical operators have a lower precedence than arithmetic or relational operators. Among logical operators, the AND operator has higher precedence than the OR operator.

**Caution** • Unlike C++, InstallShield performs complete Boolean evaluations of logical expressions. Consider the following if statement:

```
if (iVar = 10) && (MyFunction( ) = 0) then
    MessageBox("That is so true.", INFORMATION);
endif;
```

MyFunction will be called even if the expression to the left of the logical operator is false. To obtain the effect of short circuit Boolean evaluations (in which the expression to the right of the && is resolved only if the expression to the left of the && is true), use a nested if statement, as shown below:

```
if (iVar = 10) then
    if (MyFunction( ) = 0) then
        MessageBox("That is so true.", INFORMATION);
    endif;
endif;
```

## Member Operator (.)

Use the member operator to reference individual elements in a structure variable. The member operator must appear between the structure variable name and the element name, with no intervening space. In the example below, a literal value is assigned to each element in a structure variable.

```
typedef SETTINGSREC
begin
    BOOL bSwitchOn;
    STRING szMssg[255];
    INT nVal;
end;

SETTINGSREC settings;

settings.bSwitchOn = FALSE;
settings.szMssg = "Off";
settings.nVal = 0;
```

## Relational Operators (<, >, =, <=, >=, !=)

Relational operators compare one expression to another within the context of a conditional statement, such as an if or while statement. For example, the following statement asks “Is x greater than 20?”:

```
if (x > 20) then
```

The answer to the questions can be only TRUE (1) or FALSE (0). The InstallScript compiler recognizes the relational operators listed in the table below:

**Table 4** • Relational Operators

| Symbol | Operation                | Example | Description                              |
|--------|--------------------------|---------|------------------------------------------|
| =      | Equal                    | x = y   | True if x is equal to y.                 |
| >      | Greater than             | x > y   | True if x is greater than y.             |
| <      | Less than                | x < y   | True if x is less than y.                |
| >=     | Greater than or equal to | x >= y  | True if x is greater than or equal to y. |
| <=     | Less than or equal to    | x <= y  | True if x is less than or equal to y.    |
| !=     | Not equal to             | x != y  | True if x is not equal to y.             |

When you use a relational operator in an if...else statement, the program will follow one of two actions:

- If the expression is TRUE, statements that follow the if *are* executed. Statements that follow the else *are not* executed.
- If the expression is FALSE, statements that follow the if *are not* executed. Statements that follow the else *are* executed.

Relational operators have an overall lower precedence than arithmetic operators. Among just relational operators, less than, less than or equal to, greater than, and greater than or equal to have precedence over equal and not equal.

**Caution** • You cannot use assignment and relational operators in the same conditional expression. For example, the following will fail:

```
if ((ListID = ListCreate (NUMBERLIST)) = LIST_NULL) then . . . endif;
```

**Tip** • Unlike C, which uses == to test for equality, InstallScript's assignment operator and relational operator use the same symbol (=).

## Relational Operator Precedence

Relational operators have an overall lower precedence than arithmetic operators. This means that InstallShield performs all arithmetic operations before beginning to evaluate logical operations. Logical expressions are evaluated from left to right, unless the order of operations is modified by parentheses. Among relational operators the order of precedence is as follows:

- First, less than ( < ), less than or equal to ( <= ), greater than ( > ), and greater than or equal to ( >= ).
- Then, equal to ( = ) and not equal to ( != ).

Therefore, when combining arithmetic and relational expressions, the InstallShield Script Compiler evaluates precedence in the following order:

1. Negative (minus) unary.
2. Multiplication and division.
3. Addition and subtraction.
4. Less than ( < ), less than or equal to ( <= ), greater than ( > ), and greater than or equal to ( >= ).
5. Equal to ( = ) and not equal to ( != ).

In the expression `6 + 7 > y`, the InstallScript compiler adds 6 and 7 together and then compares the result (13) to `y`. To change the order of precedence, use parentheses. For example, in the expression `6 + (7 > y)`, the InstallScript compiler first determines if 7 is greater than `y`. If it is, then 1 (the numeric value of TRUE) is added to 6. If it is not, then 0 (the numeric value of FALSE) is added to 6.

When a statement contains arithmetic, relational, and logical operators, the compiler evaluates precedence in the following order:

1. Negative (minus) unary has first precedence.
2. Multiplication and division have second precedence.
3. Addition and subtraction have third precedence.
4. NOT ( ! ) has fourth precedence.
5. Less than ( < ), less than or equal to ( <= ), greater than ( > ), and greater than or equal to ( >= ) have fifth precedence.
6. Equal to ( = ) and not equal to ( != ) have sixth precedence.
7. AND ( && ) has seventh precedence.
8. OR ( || ) has eighth precedence.

Use logical operators in if and while statements the same way you used relational operators. The example below adds `nExampleSize` and `nHelpSize` if `bInstallExample` and `bInstallHelp` are true.

```
if (bInstallExample && bInstallHelp) then
    nTotalSize = nExampleSize + nHelpSize;
endif;
```

The next example sets `bPublicFile` to TRUE if *either* `bInstallProgram1` or `bInstallProgram2` is TRUE.

```
if (bInstallProgram1 || bInstallProgram2) then
    bPublicFile = TRUE;
endif;
```

**Note** • You cannot use the `&&` or `||` operators within an argument to a function. Instead, follow the above example and assign the value of the logical expression to a Boolean variable and then call the function with the variable as an argument.

## String Operators (^, +, %)

The string operators allow you to directly manipulate strings without the use of functions. Note that string operators are not case-sensitive. The InstallScript compiler supports the following string operations:

**Table 5** • String Operators

| Operation                    | Description                                                                    |
|------------------------------|--------------------------------------------------------------------------------|
| Append to Path Operator (^)  | Adds additional paths to a path or a file name.                                |
| Concatenate Operator (+)     | Appends one string to the end of another string.                               |
| Find String Operator (%)     | Locates a substring in another string.                                         |
| String Constant Operator (@) | Access a string constant that is used for one of the project's string entries. |

**Note** • Do not use parentheses to enclose expressions on either side of a string operator. For example, avoid statements like the following:

```
szPath = szTestPath ^ (AUTOFIELD + ".bat");
```

Instead, create expressions without parentheses for use with string operators, as shown below:

```
szFile = AUTOFIELD + ".bat";    szPath = szTestPath ^ szFile;
```

## String Constant Operator (@)

String entries enable you to access text strings for a given language from within your InstallScript code. That is, to keep the InstallScript code for your installation completely separate from any language-specific strings that you may want to display during the installation, you can refer to each string by using its string identifier. When you use string identifiers in your InstallScript, you must precede them with the at sign (@).

The String Editor view shows the collection of language-independent identifiers and corresponding language-specific values for your project. To learn more, see [Localizing the End-User Interface](#).

When you build a project that includes an InstallScript file (.rul) and the InstallScript code contains one or more references to string entries that use the @ operator, InstallShield validates the string entries at build time. If a string identifier in the project's InstallScript file is not defined in String Editor view, InstallShield displays build warning -7174.

**Note** ▪ The @ operator is case-insensitive when it comes to string identifiers. Therefore, when you use a string identifier in your script, you do not necessarily need to match the case of the string identifier that is specified in the String Editor view. However, mixing case may prevent InstallShield from matching the string entries in the script to the corresponding string entries in the String Editor view at build time. Therefore, it is recommended that you use uppercase for all instances of string identifiers.

**Tip** ▪ As an alternative to the @ operator, you can use the **LoadStringFromStringTable** function if you want to provide your own missing string error handling.

## Structure Pointer Operator (->)

Use the structure pointer operator to reference individual elements in a structure by means of a pointer variable. The structure pointer operator must appear between the pointer variable name and the element name, with no intervening space. In the example below, a literal value is assigned to each element in a structure.

```
typedef  DIMENSIONS
begin
    SHORT sLength;
    SHORT sWidth;
end;
DIMENSIONS Table;
NUMBER   nvNumValue;
DIMENSIONS POINTER   pointerObject;
begin
    pointerObject = &Table;
    pointerObject->sLength = 500;
    pointerObject->sWidth = 750;
```

**Caution** ▪ You can use only one structure pointer in an expression. If structure A contains a member (Bptr) that is a pointer to structure B, which contains a member (Cptr) that is a pointer to structure C, you cannot reference a member of C from A. The expression A.Bptr->Cptr->Cmember is invalid in InstallScript.

## Find String Operator (%)

Use the boolean Find String operator ( % ) to determine if one string is a substring of another string. The following example tests szStringVarA to determine if it contains the string “sample.” If it does, then MessageBox is called to display a message.

```
szStringVarA = "This is a sample string.";
if (szStringVarA % "sample") then
    MessageBox("Variable contains 'string'.", INFORMATION);
endif;
```

The character comparison is not case-sensitive. In the following example, the message box will be displayed:

```
typedef  DIMENSIONS
begin
```

```
        SHORT sLength;  
        SHORT sWidth;  
    end;  
  
    DIMENSIONS Table;  
    NUMBER    nvNumValue;  
    DIMENSIONS POINTER    pointerObject;  
  
    begin  
        pointerObject = &Table;  
        pointerObject->sLength = 500;  
        pointerObject->sWidth = 750;  
    end
```

---

**Note** ▪ The `InstallScript` function `StrFind` also determines if a substring is contained within another string. If the substring is found, `StrFind` returns its position within the string.

# Objects and Object Handlers

This section describes the objects and object handlers that InstallScript supports.

## Objects

InstallScript supports the following objects.

**Table 1** • InstallScript Objects

| Object                | Description                                                                                                                                                                                             |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Err Object</b>     | Use for exception handling.                                                                                                                                                                             |
| <b>Objects Object</b> | Obtain access to your project's InstallShield objects by either index or name.                                                                                                                          |
| <b>Reboot Object</b>  | Pass command-line arguments to the installation after a reboot. This information is written to the appropriate registry key at the end of the installation, so that the installation runs after reboot. |
| <b>TextSub Object</b> | Make text substitutions.                                                                                                                                                                                |

## Err Object

The Err object is used for exception handling. It has the following properties and methods:

## Properties

**Table 2** • Err Object Properties

| Property            | Description                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Number</b>       | A number that identifies the error.                                                                                     |
| <b>Source</b>       | A string that identifies the source of the error.                                                                       |
| <b>Description</b>  | A string that describes the error.                                                                                      |
| <b>HelpFile</b>     | A string that specifies the fully qualified file name of a help file containing additional information about the error. |
| <b>HelpContext</b>  | A number that specifies the identifier of a help topic containing additional information about the error.               |
| <b>LastDllError</b> | This property holds the return value of the Windows API function <b>GetLastError</b> .                                  |

## Methods

**Table 3** • Err Object Methods

| Method       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Clear</b> | Clears the values of the Err object's properties.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Raise</b> | <p>If executed after the try keyword, script processing passes to the next exception handler (that is, code inside a catch/endcatch block); otherwise processing passes to the setup engine's built-in exception handler. Also resets the values of Err object properties as follows:</p> <ul style="list-style-type: none"> <li>• <code>Err.Raise( );</code>—Does not reset any Err object property values.</li> <li>• <code>Err.Raise( nNumber );</code>—Resets the value of Err.Number to nNumber.</li> <li>• <code>Err.Raise( nNumber, szSource );</code>—Resets the value of Err.Number to nNumber and Err.Source to szSource.</li> <li>• <code>Err.Raise( nNumber, szSource, szDesc );</code>—Resets the value of Err.Number to nNumber, Err.Source to szSource, and Err.Description to szDesc.</li> <li>• <code>Err.Raise( nNumber, szSource, szDesc, szHelpFile );</code>—Resets the value of Err.Number to nNumber, Err.Source to szSource, Err.Description to szDesc, and Err.HelpFile to szHelpFile.</li> <li>• <code>Err.Raise( nNumber, szSource, szDesc, szHelpFile, nHelpContext );</code>—Resets the value of Err.Number to nNumber, Err.Source to szSource, Err.Description to szDesc, Err.HelpFile to szHelpFile, and Err.HelpContext to nHelpContext.</li> </ul> |

## Objects Object

**Project** ▪ This information applies to InstallScript projects.

The Objects object is used for getting access to your project's InstallShield objects by either index or name; for example:

```
set obj1 = Objects(1);
set obj2 = Objects("New MFC 6.2 Runtime 1");
```

### Properties

**Table 4** ▪ Objects Object Properties

| Property     | Description                                                   |
|--------------|---------------------------------------------------------------|
| <b>Count</b> | The number of InstallShield objects included in your project. |

## Reboot Object

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The Reboot object is used for passing command-line arguments to the Setup.exe file after a restart; this information is written to the appropriate registry key at the end of the installation, so that the installation runs after the system is restarted. For example, the following statement runs the installation in debug mode after a restart:

```
Reboot.CommandLine = "-d";
```

Note that the specified argument or arguments are added to the existing command line; they do not replace the existing command line. Note also that currently you cannot change the existing command line or remove text from it.

### Passing Parameters to the InstallScript Variable CMDLINE in an InstallScript MSI Installation

As with any Setup.exe command line, in an InstallScript MSI installation, if you are trying to pass information to the InstallScript variable CMDLINE variable when the Setup.exe file is launched after the restart, you must include the information after specifying the -z option. For example, the following adds **TEST1 TEST2** to the reboot string and thus the CMDLINE variable when the Setup.exe file is launched after the restart.

```
Reboot.CommandLine = -z"TEST1 TEST2"
```

Note that since multiple -z parameters are not supported, you must specify all information that is intended for the CMDLINE variable in a single Reboot.CommandLine call for your InstallScript MSI installation.

## TextSub Object

**Project** - This information applies to InstallScript projects.

The TextSub object is used for making text substitutions. It has the following property and method:

### Properties

**Table 5** • TextSub Object Properties

| Property                     | Description                                                          |
|------------------------------|----------------------------------------------------------------------|
| <b>Value( szIdentifier )</b> | The value of the string associated with the identifier szIdentifier. |

### Methods

**Table 6** • TextSub Object Methods

| Method                        | Description                                                                         |
|-------------------------------|-------------------------------------------------------------------------------------|
| <b>Substitute( szString )</b> | Replaces all angle-bracketed identifiers in szString with their associated strings. |

### Example

The following code:

```
TextSub.Value( "SUBBED" ) = "substituted text";
szString = "123<SUBBED>456<UNSUBBED>789";
TextSub.Substitute( szString );
```

gives szString the value "123substituted text456<UNSUBBED>789".

## Object Handlers

InstallScript supports the following object handlers.

**Table 7** • InstallScript Object Handlers

| Object Handler        | Description                                                                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InitProperties</b> | Executed when the object is inserted in a project. It initializes the values of the object script's variables that are used to read or write the values of object properties.                                                    |
| <b>ReadProperties</b> | Executed when the object project is opened and when an installation that includes the object is launched. It calls the appropriate ReadxxxxProperty functions to retrieve the property values stored in the property bag object. |

**Table 7** ■ InstallScript Object Handlers (cont.)

| Object Handler         | Description                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WriteProperties</b> | Executed when the object project is saved or built. It calls the appropriate WritexxxxProperty functions to save the property values to the property bag object. |

## InitProperties

**Project** ■ This information applies to InstallScript projects.

The InitProperties handler is executed when the object is inserted in a project. It initializes the values of the object script's variables that are used to read or write the values of object properties.

If you add a property to the object project by using the Add New Property dialog box, an appropriate statement, based on your entry in the dialog box's Default Value edit box, is automatically placed in this handler.

## ReadProperties

**Project** ■ This information applies to InstallScript projects.

The ReadProperties handler is executed when the object project is opened and when a setup that includes the object is launched. It calls the appropriate ReadxxxxProperty functions to retrieve the property values stored in the property bag object. (Property values are saved to the property bag object by the WritexxxxProperty functions, which are called by the WriteProperties handler.)

If you add a property to the object project by using the Add New Property dialog box, an appropriate ReadxxxxProperty function call is automatically placed in this handler.

## WriteProperties

**Project** ■ This information applies to InstallScript projects.

The WriteProperties handler is executed when the object project is saved or built. It calls the appropriate WritexxxxProperty functions to save the property values to the property bag object. (Property values are retrieved from the property bag object by the ReadxxxxProperty functions, which are called by the ReadProperties handler.)

If you add a property to the object project by using the Add New Property dialog box, an appropriate WritexxxxProperty function call is automatically placed in this handler.

# Exception Handling

Exception handling lets you separate error handling from the rest of your script code. InstallScript supports exception handling with the Err object and the keywords try, catch, and endcatch.

If an exception is raised during execution of code that follows the try keyword, script processing passes to the next exception handler (that is, code inside a catch/endcatch block). After an exception handler has executed, processing passes to the line after its endcatch keyword. If no exception is raised by code that follows the try keyword, the code in the exception handler is skipped and processing resumes with the line after the endcatch keyword.

An exception can be raised by a call to the Err object's Raise method, which takes from zero to five arguments. You can retrieve the values of those arguments in the exception handler by checking the value of the corresponding Err object properties.

**Note** - Raised errors must be negative numbers; otherwise, the installation engine converts the error into the appropriate COM error. Therefore, any error code thrown should be a negative number.

The following code sample demonstrates exception handling:

```
askfile:
AskText( "Path to file?", "", svPathName );

try
    if (!Is( FILE_EXISTS, svPathName )) then
        /* If file does not exist, raise an exception.
           (ERR_NOT_EXIST must have been given a value
            in a #define statement. The error number
            must be a negative number.) */
        Err.Raise( ERR_NOT_EXIST );
    endif;

    if GetFileInfo ( svPathName, FILE_SIZE,
        nvFileSize, svResult )<0 then
        /* If file information could not be obtained,
           raise an exception. (ERR_NO_INFO must have been
            given a value in a #define statement. The error
            number must be a negative number.) */
        Err.Raise ( ERR_NO_INFO );
    endif;

    SprintfBox ( INFORMATION, "File Size", "Size of %s is %ld.",
        svPathName, nvFileSize );
catch
    /* Exception handler. */
    nTemp = Err.Number;
    /* Handle the exception based on its cause. */
    switch (nTemp)
        case ERR_NOT_EXIST:
            if AskYesNo( svPathName +
                " does not exist. Enter another path?", YES )=YES then
                bTryAgain = TRUE;
            endif;
        case ERR_NO_INFO:
```

```

        MessageBox ( "Could not get size of " +
                    svPathName, INFORMATION );
        bTryAgain = FALSE;
    endswitch;
endcatch;

if bTryAgain then
    bTryAgain = FALSE;
    goto askfile;
endif;

```

Try/catch/endcatch blocks can be nested as in the following example:

```

try
    /* Normal processing, part 1. */
    try
        /* Normal processing, part 2. */
        catch
            /* Exception handling for part 2. */
        endcatch;
    /* Normal processing, part 3. */
catch
    /* Exception handling for parts 1 and 3. */
endcatch;

```

# Built-In Functions (A-D)

For a list of functions by category, see [Built-In Functions by Category](#).

## AddFolderIcon

The [CreateShortcut](#) function supersedes the **AddFolderIcon** function.

The **AddFolderIcon** function lets you perform tasks such as the following:

- Create a shortcut or folder on the Start menu, the Programs menu, or the desktop. Use the `szProgramFolder` parameter to specify the appropriate location for the shortcut or folder.
- Create a cascading submenu on the Startup menu, and include a shortcut in the submenu.

---

**Note** ▪ The shortcut target must be present on the target system before **AddFolderIcon** can be called.

**AddFolderIcon** does not support the creation of Internet shortcuts.

### Syntax

```
AddFolderIcon ( szProgramFolder, szItemName, szCommandLine, szWorkingDir, szIconPath, nIcon,
                szShortCutKey, nFlag );
```

## Parameters

**Table 1** • AddFolderIcon Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szProgramFolder</b> | <p>Specify the name of the folder that should contain the shortcut, or specify the name of the program folder that you want to create. If the folder does not exist, the installation creates it. For this parameter, you can specify a subfolder in a multi-level cascading menu. If the subfolder does not exist, <b>AddFolderIcon</b> creates the subfolder and, if necessary, its parent folders.</p> <p>To add the shortcut to a specific folder, specify the fully qualified path—for example:</p> <pre>C:\ProgramData\Microsoft\Windows\Start Menu\Programs</pre> <p>To add a shortcut to the Programs menu on the Start menu, you can pass a null string ("") in this parameter.</p> <p>You can pass one of the following InstallScript system variables in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FOLDER_DESKTOP</b>—Adds the shortcut to the desktop.</li> <li>● <b>FOLDER_STARTUP</b>—Adds the shortcut to the Startup menu.</li> <li>● <b>FOLDER_STARTMENU</b>—Adds the shortcut to the Start menu.</li> <li>● <b>FOLDER_PROGRAMS</b>—Adds the shortcut to the Start\Programs menu.</li> </ul> <p>You can also specify a path relative to a folder that is identified by an InstallScript system variable—for example:</p> <pre>FOLDER_PROGRAMS ^ "ACCESSORIES\GAMES"</pre> |
| <b>szItemName</b>      | <p>Specify the name of the shortcut. Calling <b>AddFolderIcon</b> to add a shortcut to a program folder also creates a link file in the links directory that is specified by szCommandLine. Note that Explorer shell does not allow the following characters in item names: /, \, :, ?, &lt;, &gt;, or  .</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>szCommandLine</b>   | <p>Specify one of the following:</p> <ul style="list-style-type: none"> <li>● The fully qualified name of the executable file that is associated with the shortcut, including any command-line parameters. This is added to the Target value on the shortcut's Properties dialog box. To add a shortcut to the Start Programs menu, enter the fully qualified path of the links directory, which is where your application stores its icon link files.</li> <li>● The fully qualified path if szItemName is a subfolder.</li> </ul> <div>  <p><b>Caution</b> • If the command line includes a long file name, it must be enclosed in quotes. Command-line parameters, however, should not be surrounded with quotation marks. For that reason, it is advisable to build the szCommandLine string from two separate strings.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 1** - AddFolderIcon Parameters (cont.)

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szWorkingDir</b>  | <p>Specify the working directory for the shortcut target.</p> <p>If szItemName is a subfolder, this parameter is not applicable.</p> <p><b>AddFolderIcon</b> writes this directory in the Start In box on the Shortcut tab of the shortcut's Properties dialog box. If you pass a null string ("") in this parameter, the function leaves this Start In box blank, and the path in the Target box is used.</p> <hr/>  <p><b>Caution</b> - Do not call <b>LongPathToQuote</b> to enclose this path in quotation marks. InstallShield automatically encloses these paths in quotation marks.</p> |
| <b>szIconPath</b>    | <p>Specify the fully qualified path to the file that contains the icon that you want to be displayed for the shortcut.</p> <p>If szItemName is a subfolder, this parameter is not applicable.</p> <hr/>  <p><b>Caution</b> - Do not call <b>LongPathToQuote</b> to enclose this path in quotation marks. InstallShield automatically encloses these paths in quotation marks.</p>                                                                                                                                                                                                              |
| <b>nlcon</b>         | <p>Specify the icon index in the executable file that is specified by szIconPath. An icon index of 0 refers to the first icon in the file, an icon index of 1 refers to the second icon, and so on. If you are not using an icon, specify 0 in this parameter.</p> <p>If szItemName is a subfolder, this parameter is not applicable.</p>                                                                                                                                                                                                                                                                                                                                       |
| <b>szShortCutKey</b> | <p>Specify the shortcut key (in the form of a string) that you want to be assigned to your shortcut. You can set szShortCutKey for the shortcut so that end users can press the appropriate hot keys to launch the shortcut.</p> <p>For example, if you want end users to be able to launch the product by pressing the CTRL key, the ALT key, and then the 1 key on the numeric keyboard, pass "Ctrl + Alt + 1" in this parameter.</p> <p>If szItemName is a subfolder, this parameter is not applicable.</p>                                                                                                                                                                  |

**Table 1** ▪ AddFolderIcon Parameters (cont.)

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nFlag</b> | <p>Pass one or more of the following predefined constants in this parameter. To pass two or more predefined constants in this parameter, combine those constants with the bitwise OR operator (   ).</p> <ul style="list-style-type: none"> <li>● <b>REPLACE</b>—Indicates that the current icon or shortcut in the folder is to be replaced.</li> <li>● <b>RUN_MAXIMIZED</b>—Indicates that the program should be maximized when launched.</li> <li>● <b>RUN_MINIMIZED</b>—Indicates that the program should be minimized when launched.</li> <li>● <b>NULL</b>—Indicates no options.</li> </ul> |

## Return Values

**Table 2** ▪ AddFolderIcon Return Values

| Return Value  | Description                                                                                                                                                                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully added or replaced the shortcut in the specified folder and associated the executable file with it.                                                                                                                                                        |
| <b>&lt; 0</b> | <p>Indicates that the function was unable to add or replace the shortcut and associate the executable file with it.</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

## AddFolderIcon Examples

Choose one of the following examples:

- [Place a shortcut to an executable file on the Start menu and the Start Programs menu.](#) (AddFolderIcon Example 1)
- [Create a cascading submenu on the Startup menu and add a shortcut to the menu.](#) (AddFolderIcon Example 2)
- [Place a subfolder on the desktop and a shortcut pointing to an executable file in the new folder.](#) (AddFolderIcon Example 3)

### AddFolderIcon Example 1

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the AddFolderIcon function.
*
* This example places a shortcut to an executable file on the
* Start menu and the Start Programs menu.
*
* Note: Before running this script, set the preprocessor
*       constants so that they reference the fully qualified
*       names of the Windows Notepad executable and a valid
*       text file on the target system.
*
\*-----*/

#define PROGRAM "C:\\Windows\\Notepad.exe"
#define PARAM   "C:\\Windows\\Readme.txt"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_AddFolderIcon(HWND);

szIconPath = "";
nIcon = 0;
szShortCutKey = "";
nFlag = REPLACE|RUN_MAXIMIZED;

// Add the shortcut to the submenu; create the submenu if necessary.
nResult = AddFolderIcon (szProgramFolder, szItemName, szCommandLine,
                        szWorkingDir, szIconPath, nIcon,
                        szShortCutKey, nFlag);

// Report the results.
if (nResult < 0) then
    MessageBox ("AddFolderIcon failed.", SEVERE);
else
    sprintfBox (INFORMATION, "AddFolderIcon", "%s created successfully.",
                szItemName);
endif;

end;

```

## AddFolderIcon Example 3

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the AddFolderIcon function.
*
* This example places a subfolder on the desktop and an icon
* pointing to an executable in the new folder. The folder is
* a shortcut that points to an actual directory. From this
* folder the user can execute a shortcut that runs the program.
*
* Note: Before running this script, set the preprocessor
* constants so that they reference the fully qualified
* names of the Windows Notepad executable and a valid
* text file on the target system.
*
\*-----*/

```

```

#define FOLDER      "C:\\Windows\\"
#define PROGRAM     "C:\\Windows\\Notepad.exe"
#define PARAM       "C:\\Windows\\Readme.txt"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_AddFolderIcon(HWND);

function ExFn_AddFolderIcon(hMSI)
    STRING  szProgramFolder, szItemName, szCommandLine, szWorkingDir;
    STRING  szIconPath, szShortCutKey;
    STRING  szProgram, szParam, szFolderDir;
    NUMBER  nIcon, nFlag, nResult;
begin

    // szProgramFolder is the Desktop on the local system.
    szProgramFolder = FOLDER_DESKTOP;
    szItemName      = "Example folder";

    // Create the folder which the folder icon will point to.
    szFolderDir = FOLDER ^ szItemName;

    MessageBox ("AddFolderIcon failed.", SEVERE);
else
    sprintfBox (INFORMATION, "AddFolderIcon", "%s created successfully.",
                szItemName);
endif;

end;

```

## AddProfString

The **AddProfString** function unconditionally adds a profile string to an .ini file. Use AddProfString only to add non-unique keys, such as those found in the [386Enh] section of the System.ini file (device = ...). AddProfString adds the line KEY=VALUE to the end of the specified .ini file section. It does not replace or update an existing key. To update an existing non-unique key, call [ReplaceProfString](#). To add a unique key or to update an existing unique key's value in an .ini file, call [WriteProfString](#).

### Syntax

```
AddProfString ( szFileName, szSectionName, szKeyName, szValue );
```

## Parameters

**Table 3** • AddProfString Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>    | Specifies the name of the .ini file to which the profile string is to be added. If szFileName is unqualified (that is, if a drive designation and path are not included), InstallShield searches for the file in the Windows folder. If the file does not exist, it is created in the specified folder; if a path is not included in file name, the file is created in the Windows folder. If the file name is qualified with a path that does not exist, AddProfString fails. |
| <b>szSectionName</b> | Specifies the name of a section in the .ini file section. The profile string is inserted at the end of that section. If the section does not exist, InstallShield creates it. The section name should <i>not</i> be enclosed within delimiting brackets ( [ ] ). Note that the profile string is inserted even if the key specified by szKeyName already exists in that section.                                                                                               |
| <b>szKeyName</b>     | Specifies the name of the key to insert. The value of this parameter will appear to the left of the equal sign in the profile string (szKeyName = szValue).                                                                                                                                                                                                                                                                                                                    |
| <b>szValue</b>       | Specifies the value to assign to the key. The value of this parameter will appear to the right of the equal sign in the profile string (szKeyName = szValue).                                                                                                                                                                                                                                                                                                                  |

## Return Values

**Table 4** • AddProfString Return Values

| Return Value  | Description                                                                     |
|---------------|---------------------------------------------------------------------------------|
| <b>0</b>      | AddProfString successfully added the specified profile string to the .ini file. |
| <b>&lt; 0</b> | AddProfString was unable to add the profile string.                             |

## Additional Information

- AddProfString does not use the Windows API to change the .ini files. The Windows API cannot handle the types of changes possible with AddProfString.
- Changes made to .ini files can be logged for uninstallation. However, there are some important restrictions to be aware of. For more information, see Uninstalling Initialization (.ini) File Entries.

## AddProfString Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the functions AddProfString and GetProfString.
*
* This script adds a profile string to a file; then it
* retrieves and displays the string that was added.
*
* Note: The first time you run this script, it will create a
*       file named ISExempl.ini in the root of drive C. You
*       can delete that file when you have finished analyzing
*       this script.
*
\*-----*/

#define EXAMPLE_INI "C:\\ISExempl.ini"

// The new section, key, and value to add to the file.
#define NEW_SECTION "New Section"
#define NEW_KEY      "New Key"
#define NEW_VALUE    "Test"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_AddProfString(HWND);

function ExFn_AddProfString(hMSI)
    STRING svResult;
begin

    // Add the profile string to the file.
    if (AddProfString (EXAMPLE_INI, NEW_SECTION, NEW_KEY, NEW_VALUE) != 0) then
        // Display an error message if the string could not be added.
        MessageBox ("AddProfString failed.", SEVERE);
    else
        // Retrieve the value of a key from the file.
        if (GetProfString (EXAMPLE_INI, NEW_SECTION, NEW_KEY, svResult) != 0) then
            // Display an error message if the string could not be retrieved.
            MessageBox ("GetProfString failed.", SEVERE);
        else
```

```

        // Display the key and its current value.
        MessageBox (NEW_KEY + "=" + svResult, INFORMATION);
    endif;
endif;

end;

```

## AdminAskPath

---

**Project** ▪ This information applies to InstallScript MSI projects.

The **AdminAskPath** function displays a dialog that prompts the end user to enter the path to a destination location for an administrative installation (when the end user runs an InstallScript MSI project Setup.exe with the /a argument).

### Syntax

```
AdminAskPath ( szMsg, szDefaultPath, svResultPath );
```

## Parameters

**Table 5** • AdminAskPath Parameters

| Parameter            | Description                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b>         | Specifies the message to display in this dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                        |
| <b>szDefaultPath</b> | Specifies the default path to display in the edit field. The end user can modify this string. The default implementation of OnAdminInstallUIBefore passes INSTALLDIR in this parameter.                                                                 |
| <b>svResultPath</b>  | Returns the resulting path, regardless of whether the user accepts the default path, modifies it, or selects an alternate path from the Choose Folder dialog. The default implementation of OnAdminInstallUIBefore passes INSTALLDIR in this parameter. |

## Return Values

**Table 6** • AdminAskPath Return Values

| Return Value     | Description                                      |
|------------------|--------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the user clicked the Back button. |

## Additional Information

**AdminAskPath** uses the **AskPath** dialog, and it uses the same dialog resources as **AskPath**. Therefore, any changes you make to the layout of **AskPath** in the Dialog Editor are reflected in **AdminAskPath**.

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## AdminAskPath Example

**Project** • This information applies to InstallScript MSI projects.

```
//-----
//
// InstallShield Example Script
//
// Demonstrates the AdminAskPath function.
//
// In the OnAdminInstallUIBefore event of an InstallScript MSI project,
// prompt the user for the target directory into which files should be
// uncompressed and copied.
```

```
//
//-----

function OnAdminInstallUIBefore( )
    int nResult;

begin
    Dlg_SdWelcome:
        SdWelcome("", "");

    Dlg_AdminAskPath:
        // prompt the user for the target path, storing it in INSTALLDIR
        nResult = AdminAskPath("", INSTALLDIR, INSTALLDIR);
        if (nResult = BACK) goto Dlg_SdWelcome;

        // prepare the status dialog
        SetStatusExStaticText(SdLoadString(IDS_IFX_STATUSEX_STATICTEXT_FIRSTUI));
        Enable(STATUSEX);
end;
```

## AskDestPath

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **AskDestPath** function displays a dialog that enables the end user to specify a destination folder for the files to be installed by your installation. The dialog also includes a Browse button that enables the end user to select an existing folder on the system.

To open the Choose Folder dialog from the Choose Destination Location dialog, the end user must click the Browse button. The Choose Folder dialog displays a list of all available folders. The end user can select an existing folder or enter a new folder name. If the end user enters the name of a folder that does not exist, a message box opens to enable the end user to create the folder.

**Note** ▪ Installations that run in silent mode should create the new folder if it does not exist before calling **AskDestPath**. This ensures that the confirmation dialog is not displayed. Without this step, two response files are required to handle the two possible conditions.

The folder selected by the end user must be writable; non-writable folders are not accepted. If you want the end user to be able to select folders that are not writable, call the **AskPath** function instead.

### Syntax

```
AskDestPath ( szTitle, szMsg, svDir, nReserved );
```

## Parameters

**Table 7** • AskDestPath Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title Choose Destination Location, pass a null string ("" ) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>szMsg</b>     | Specifies the message to display in the dialog. To pass multiple lines of static text in this parameter, insert newline escape sequences ( \n ) where needed to break the line. To display the default instructions for this dialog, pass a null string ("" ) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>svDir</b>     | <p>Specifies the default path to display when the dialog is opened; returns the path to the folder selected by the end user.</p>  <p><b>Note</b> ▪ If the default folder specified by svDir does not already exist on the end user's system, it is not created unless the end user clicks the Browse button and follows the steps to create it from the Choose Folder dialog. Therefore, whenever you specify a default folder that you intend to use before calling <a href="#">FeatureMoveData</a> (which creates the folder if necessary), you must call <a href="#">ExistsDir</a> when AskDestPath returns in order to determine whether that folder exists. If it does not exist, call <a href="#">CreateDir</a> to create it on the end user's system. Note that <a href="#">FeatureTransferData</a> is called automatically in an installation running an event-based script.</p> |
| <b>nReserved</b> | The value of this parameter must be 0 (zero).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Return Values

**Table 8** • AskDestPath Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## AskDestPath Example

**Project** - This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the AskDestPath function.
 *
 * This script calls AskDestPath to get the path to the location
 * where the installation will install files. That path is then
 * displayed in a message box.
 *
 \*-----*/

#define TITLE_TEXT "AskDestPath Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_AskDestPath(HWND);

function ExFn_AskDestPath(hMSI)
    STRING szTitle, szMsg, svDir;
    NUMBER nReturn;
begin

    // Set a default path for the installation.
    svDir = INSTALLDIR;

    // Get a destination directory. Pass a null string in the
    // second parameter to display the default message.
    nReturn = AskDestPath (TITLE_TEXT, "", svDir, 0);

    if (nReturn < 0) then
        // Report the error.
        MessageBox ("AskDestPath failed.", SEVERE);
    elseif (nReturn = NEXT) then
        // Display the selected destination directory name.
        MessageBox ("You selected " + svDir + ".", INFORMATION);
    endif;

end;
```

## AskOptions

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **AskOptions** function formats and displays a dialog that prompts the end user to select one or more options. The dialog displays up to nine selection controls—either check boxes or option buttons—depending on the value of `nValue`.

The default title for this dialog is Select Features. To change the contents of the title bar, call **SetDialogTitle** before calling **AskOptions**.

---

**Note** ▪ You cannot use the **PlaceWindow** function in conjunction with the **AskOptions** function. By default, the dialog appears in the center of the desktop, unless the background window mode is enabled. If the installation is in window mode, the dialog appears in the center of the background window.

## Syntax

```
AskOptions ( nValue, szMsg, szText1, bvCheck1, szText2, bvCheck2[, szTextn, bvCheckn] [,..., ...] );
```

## Parameters

**Table 9** • AskOptions Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nValue</b>   | <p>Specifies the type of controls to display. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>EXCLUSIVE</b>—Specifies option buttons, which enable the end user to select only one option.</li> <li>● <b>NONEXCLUSIVE</b>—Specifies check boxes, which enable the end user to select more than one option.</li> </ul>                                                                                                                                                                                                                                                                                                                         |
| <b>szMsg</b>    | <p>Specifies the message to display in the dialog. You can use this message to describe the options and/or ask the user to choose one or more options. If the message is too long for one line, use newline escape sequences ( \n ) to insert line breaks.</p>  <p><b>Note</b> ▪ Your operating system dictates the maximum message string length. By default, the display of szMsg text is limited to two lines by the AskOptions dialog resource in _Isres.dll. To display more than two lines of szMsg text, you can create a custom dialog from the AskOptions dialog.</p>                                                 |
| <b>szText1</b>  | <p>Specifies a text label to display next to the first check box or option button. The maximum number of characters that can be displayed depends on the font you use; be sure to check that the string specified fits in the static text field of the dialog. If the string does not fit, either shorten it or call <b>SdAskOptions</b> instead.</p> <p>To create an accelerator key, insert an ampersand (&amp;) before the character you want to designate for that purpose. The character is displayed with an underline to indicate its function. For example, to make Alt + C the accelerator key for Custom, pass "&amp;Custom"; to make Alt + S the accelerator key for Custom, pass "Cu&amp;stom."</p> |
| <b>bvCheck1</b> | <p>Specifies the initial status of the first check box or option button when the dialog is opened; returns the status of the first check box or option button when the dialog is closed. The following constants are passed and returned in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—The first check box or option button is selected.</li> <li>● <b>FALSE</b>—The first check box or option button is not selected.</li> </ul>                                                                                                                                                                                                                                                 |
| <b>szText2</b>  | <p>Specifies a text label to display next to the second check box or option button. The maximum number of characters that can be displayed depends on the font you use; be sure to check that the string specified fits in the static text field of the dialog. If the string does not fit, either shorten it or call <b>SdAskOptions</b> instead.</p> <p>Create an accelerator in the same manner as you did for szText1.</p>                                                                                                                                                                                                                                                                                  |

**Table 9** ▪ AskOptions Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bvCheck2</b> | <p>Specifies the initial status of the second check box or option button when the dialog is opened; returns the status of the second check box or option button when the dialog is closed. The following constants are passed and returned in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—The first check box or option button is selected.</li> <li>● <b>FALSE</b>—The first check box or option button is not selected.</li> </ul> <p>Up to seven additional options can be defined. Each additional option is indicated by a pair of parameters—a string parameter that defines a label and a number variable that indicates the state of the option when AskOptions returns. To set the initial state of an option, assign TRUE or FALSE to the number variable before calling AskOptions.</p> <div>  </div> <p><b>Note</b> ▪ If <i>nValue</i> is <i>EXCLUSIVE</i> and the initial state of more than one option is set to <i>TRUE</i>, AskOptions preselects the first option in the parameter list that is set to <i>TRUE</i>.</p> |

## Return Values

**Table 10** ▪ AskOptions Return Values

| Return Value     | Description                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. The states of the controls are returned in the individual bvCheck variables. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. The states of the controls are returned in the individual bvCheck variables. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## AskOptions Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
*
```

```

* InstallShield Example Script
*
* Demonstrates the AskOptions function.
*
* The AskOptions dialog is displayed twice. First, it is
* displayed with check boxes; then it is displayed with option
* buttons. The example shows the maximum number of options
* allowed--nine.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_AskOptions(HWND);

                szText1, nvCheck1,
                szText2, nvCheck2,
                szText3, nvCheck3,
                szText4, nvCheck4,
                szText5, nvCheck5,
                szText6, nvCheck6,
                szText7, nvCheck7,

```

```

        szText8, nvCheck8,
        szText9, nvCheck9);

    // Display the option button (EXCLUSIVE) dialog.
    nValue = EXCLUSIVE;
    AskOptions (nValue, szMsg,
        szText1, nvCheck1,
        szText2, nvCheck2,
        szText3, nvCheck3,
        szText4, nvCheck4,
        szText5, nvCheck5,
        szText6, nvCheck6,
        szText7, nvCheck7,
        szText8, nvCheck8,
        szText9, nvCheck9);

end;

```

## AskPath

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **AskPath** function displays a dialog that prompts the end user to enter the path to a destination location. The dialog contains a single-line edit field in which you can display a default path. The end user has three options:

- Accept the default path.
- Edit the default path.
- Display the Choose Folder dialog to select a folder.

To open the Choose Folder dialog, the end user must click the Browse button. The Choose Folder dialog displays a list of all available folders. The end user can select an existing folder or enter a new folder name. If the end user enters the name of a folder that does not exist, the folder is created.

**Caution** ▪ *AskPath* does not verify the existence of the path entered by the end user. After calling *AskPath*, call *CreateDir* to create the path.

**Note** ▪ You cannot use the *PlaceWindow* function in conjunction with the *AskPath* function. By default, the dialog opens in the center of the desktop, unless the background window mode is enabled. If the installation is in window mode, the dialog opens in the center of the background window.

The default title for the dialog is Choose Destination Location. To change the title, call *SetDialogTitle* before calling *AskPath*.

The *AskPath* function accepts the name of a folder that exists but is not writable. To limit the end user's selection to writable folders, call the *AskDestPath* function instead.

## Syntax

```
AskPath ( szMsg, szDefPath, svResultPath );
```

## Parameters

**Table 11** ▪ AskPath Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b>        | Specifies the message to display in this dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>szDefPath</b>    | Specifies the default path to display in the edit field. The end user can modify this string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>svResultPath</b> | Returns the resulting path, regardless of whether the user accepts the default path, modifies it, or selects an alternate path from the Choose Folder dialog. AskPath adds a backslash to the end of the path before placing it into svResultPath. If necessary, that backslash can be removed by calling <a href="#">StrRemoveLastSlash</a> after AskPath returns. If the user clicks the Back button, the value of svResultPath will be unpredictable. Therefore, if you are using the same variable for both szDefPath and svResultPath, be sure to reinitialize that variable when the return value from AskPath is BACK. |

**Note** ▪ The edit field displayed in the dialog scrolls to accommodate long strings. Because the number of characters that can be entered into the edit field is not limited, you should declare the variable passed in svResultPath without an explicit size. If the string variable is not large enough to store the text entered by the user, the string is truncated and an error message is displayed. Because this function appends a backslash and a NULL terminator to the end of the string, the size of the string must be at least two characters longer than the path entered by the user.

## Return Values

**Table 12** ▪ AskPath Return Values

| Return Value     | Description                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button.                                            |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button; svResultPath is set to a null string (""). |

## Additional Information

**AdminAskPath** uses the **AskPath** dialog, and it uses the same dialog resources as **AskPath**. Therefore, any changes you make to the layout of **AskPath** in the Dialog Editor are reflected in **AdminAskPath**.

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## AskPath Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the AskPath function.
 *
 * This script obtains the path to a folder on the
 * end user's computer. If the path does not exist, it creates
 * a folder at that location if indicated by the
 * end user. Finally, it displays the selected path.
 *
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_AskPath(HWND);

function ExFn_AskPath(hMSI)
    STRING szMsg, svResultPath[101];
    BOOL bTargetDirOk;
begin

    // Disable the Back button in installation dialogs.
    Disable (BACKBUTTON);

    // Create the message to display in the AskPath dialog.
    szMsg = "Specify a folder for the application.";

    // Initialize valid path indicator.
    bTargetDirOk = FALSE;

    repeat
        // Get a path from the user. The default path is
        // the current value of the system variable INSTALLDIR.
        if (AskPath (szMsg, INSTALLDIR, svResultPath) = NEXT) then
            // Does the path entered by the user exist on the
            // target system?
            if (ExistsDir (svResultPath) = 0) then
                // If it exists, set indicator to exit the loop.
                bTargetDirOk = TRUE;
            else
                // If the path doesn't exist, ask if it should be created.
                if (AskYesNo ("Folder does not exist. Create it?",YES) = YES) then
                    // Attempt to create the folder (directory).
                    if (CreateDir (svResultPath) = 0) then
                        // If the folder was created, set indicator to exit the loop.

```

```

        bTargetDirOk = TRUE;
    else
        // Inform the end user that the folder was not created.
        MessageBox ("Unable to create " + svResultPath, WARNING);
    endif;
endif;
endif;
endif;
until bTargetDirOk;

// Display the name of the target folder.
MessageBox ("The target folder is " + svResultPath, INFORMATION);

// You'd also enable the Back button for subsequent dialogs.
Enable (BACKBUTTON);

end;

```

## AskText

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **AskText** function displays a dialog that contains one static text field and one edit box. Specify default text for the static text field in the parameter `szQuestion`. Specify default text for the edit box in the parameter `szDefault`.

**Note** ▪ You cannot use the [PlaceWindow](#) function in conjunction with the `AskText` function. By default, the dialog appears in the center of the desktop, unless the background window mode is enabled. If the installation is in window mode, the dialog opens in the center of the background window.

The default title of this dialog is *Enter Information*. To change the contents of the title bar, call [SetDialogTitle](#) before calling `AskText`.

### Syntax

```
AskText ( szQuestion, szDefault, svResult );
```

## Parameters

**Table 13** ▪ AskText Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szQuestion</b> | Specifies the question or statement to display. If the length of the string in this parameter exceeds the width of the static text field, one or more line breaks will be inserted into the string so that it displays on multiple lines in the dialog. If you prefer, you can format the string manually by inserting one or more newline escape sequences ( \n ) into it. This parameter does not have a default value.                                                                                                                                                                                                                                        |
| <b>szDefault</b>  | Specifies the default text for the edit box. The edit box scrolls, if necessary, to accommodate a long string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>svResult</b>   | <p>Returns the text entered by the end user when the Next button is clicked to close the dialog. If the user clicks the Back button, the value of svResult will be unpredictable. Therefore, if you are using the same variable for both szDefault and svResult, be sure to reinitialize that variable when the return value from AskText is BACK.</p>  <p><b>Note</b> ▪ The string variable that you pass in svResult must be large enough to accommodate the text entered into the edit box. For that reason, you should use the autosize method to declare the variable.</p> |

## Return Values

**Table 14** ▪ AskText Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

The dialog that is displayed by the AskText function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## AskText Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the AskText function.
 *
 * This script gets a company name from the end user.
 *
\*-----*/

#define MSG_TEXT      "Please enter your company name."
#define DEFAULT_COMPANY "My Software Company"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_AskText(HWND);

function ExFn_AskText(hMSI)
    STRING svCompany, szTitle;
    NUMBER nResult;
begin

    // Get the company name.
    nResult = AskText (MSG_TEXT, DEFAULT_COMPANY, svCompany);

    if nResult = NEXT then
        // Display the company name that was entered by the user.
        MessageBox ("Company: " + svCompany, INFORMATION);
    endif;

end;

```

## AskYesNo

**Project** ▪ This information applies to the following project types:

- Basic MSI
- InstallScript
- InstallScript MSI

The **AskYesNo** function presents a message box that displays a question that the end user can answer by clicking a Yes or No button. The **AskYesNo** message box contains four items:

- Question mark icon
- Question text
- Yes button
- No button

**Note** ▪ The default title is **Question**. To change the contents of the title bar, call [SetDialogTitle](#) before calling **AskYesNo**.

The **AskYesNo** message box is created by a direct call to the corresponding Windows API function, which displays a system modal dialog. Once a modal dialog is displayed, it retains focus until the end user closes it.

Windows displays this dialog; therefore, the installation cannot change the text of the buttons on the dialog. Windows displays the button text—"Yes" and "No" on English-based systems—in the language of the operating system; no manual localization of this text is required. If you need to display a more flexible dialog, call a Windows API function directly or use a custom dialog.

## Syntax

```
AskYesNo ( szQuestion, nDefault );
```

## Parameters

**Table 15** ▪ AskYesNo Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szQuestion</b> | Specifies the question to display in the message box. If the message is too large to fit on one line, embed newline escape characters ( \n ) in the message to insert line breaks.                                                                                                                           |
| <b>nDefault</b>   | Specifies the button that is selected by default. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li><b>YES</b>—The Yes button is highlighted when the dialog opens.</li> <li><b>NO</b>—The No button is highlighted when the dialog opens.</li> </ul> |

## Return Values

**Table 16** ▪ AskYesNo Return Values

| Return Value   | Description                                     |
|----------------|-------------------------------------------------|
| <b>YES (1)</b> | Indicates that the user clicked the Yes button. |
| <b>NO (0)</b>  | Indicates that the user clicked the No button.  |

## Additional Information

The dialog that is displayed by the **AskYesNo** function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## AskYesNo Example

**Project** ▪ This information applies to the following project types:

- Basic MSI
- InstallScript
- InstallScript MSI

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the AskYesNo function.
*
* This script asks the user whether or not to display the
* ReadMe file. If yes, the script launches the Windows
* Notepad to open a ReadMe file.
*
* Note: Before running this script, set the preprocessor
*       constants so that they reference the fully qualified
*       names of the Windows Notepad executable and a valid
*       text file on the target system.
*
\*-----*/

#define PROGRAM "C:\\Windows\\Notepad.exe"
#define PARAM   "C:\\Windows\\Readme.txt"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_AskYesNo(HWND);

function ExFn_AskYesNo(hMSI)
begin
    // Display the AskYesNo dialog. The default is set to Yes.
    if (AskYesNo("Installation complete. Would you like to read the Readme " +
        "file now?", YES) = YES) then
        LaunchApp(PROGRAM, PARAM);
    endif;
end;
```

# BatchAdd

The **BatchAdd** function inserts a SET command or other DOS command into a batch file that has been loaded into memory with **BatchFileLoad**. The parameter `nOptions` allows you to add the new command as the first or last statement in the file, replace an existing statement with the new command, or specify that the new command be added before or after an existing statement.

Before calling **BatchAdd**, you must call **BatchFileLoad** to load the file to be modified into memory. After you modify the file, call **BatchFileSave** to save it to disk.

Do not mix the Ez batch file functions with the advanced batch file functions. After calling **BatchFileLoad**, you cannot use Ez batch file functions until you have called **BatchFileSave** to save the file.

## Syntax

```
BatchAdd ( szKey, szValue, szRefKey, nOptions );
```

## Parameters

**Table 17** ▪ BatchAdd Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>    | Specifies the keyword to add to the batch file. PATH, TEMP, and MYENV are examples of valid keys for this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szValue</b>  | <p>Specifies the value of the key to be added to the batch file. This string must be no longer than 512 bytes; passing a string longer than 512 bytes will cause an installation error. To add a longer string, use the <a href="#">FileGrep</a> and <a href="#">FileInsertLine</a> functions.</p> <div>  <p><b>Caution</b> ▪ Batch files do not support long paths completely. If you are using this function to add a line that contains a long path, call <a href="#">LongPathToShortPath</a> to convert the long path to its short path equivalent before adding it to the string to be placed in the batch file. For information on long paths and long file names, refer to <i>Long File Name Format</i>.</p> </div> |
| <b>szRefKey</b> | Specifies the reference key relative to which you are adding szKey in the batch file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 17** ▪ BatchAdd Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOptions</b> | <p>Specifies where in the file to insert the line. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>BEFORE</b>—The statement is added before the first line that contains szRefKey. If szRefKey is a null string (""), the statement is added as the first line of the file.</li> <li>● <b>AFTER</b>—The statement is added after the last line that contains szRefKey. If szRefKey is a null string (""), the statement is added as the last line of the file.</li> <li>● <b>REPLACE</b>—The statement replaces an existing line in the file. If multiple lines with same key exist, only the last line is replaced. If szKey does not exist in the file, a new line will be added after szRefKey. If szRefKey is a null string (""), the new line is added as the last line of the file.</li> </ul> <p>When the statement to be added is not a SET command, pass a null string ("") in szKey, pass the complete command in szValue, and use the OR operator to combine the constant COMMAND with one of the other option constants, as shown below:</p> <pre>BatchAdd("", "PAUSE", "", COMMAND   AFTER);</pre> <div data-bbox="636 1108 672 1152" data-label="Image"></div> <p><b>Note</b> ▪ <i>BatchAdd automatically adds the DOS keyword SET to the beginning of the statement to be inserted unless you use the OR operator to combine the constant COMMAND with the value you pass in nOptions. If you do not explicitly specify REPLACE in nOptions, the specified statement is added even if a duplicate line exists in the batch file.</i></p> |

## Return Values

**Table 18** • BatchAdd Return Values

| Return Value | Description                                                                      |
|--------------|----------------------------------------------------------------------------------|
| 0            | BatchAdd successfully added a SET statement or other command to the batch file.  |
| < 0          | BatchAdd was unable to add the SET statement or other command to the batch file. |

## Additional Information

An InstallScript reference key is either an environment variable, a DOS command, or a program file name. Environment variables are keywords such as PATH, COMSPEC, LIB, or other predefined or user-defined identifiers. The value of an environment variable is established by using the DOS SET command. Statements that appear in a batch file must be either DOS commands, program names (with or without command-line parameters), or comments. Refer to your operating system manual for a detailed definition of commands and environment variables.

## BatchAdd Example

The following example applies to:

### InstallScript/InstallScript MSI Installations

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the BatchAdd function.
*
* This example script adds three statements to a batch file.
* First, it adds a PATH statement. Next, it adds a command to
* set the environment variable EXENV. Then it adds a command
* to launch SHARE.EXE, placing it before the existing command
* to start Windows. Finally, it backs up the original file
* and saves the edited file under its original name.
*
* If any of the calls to BatchAdd fails, the setup exits
* without saving changes to the batch file.
*
* Note: Before running this script, create a batch file
*      named ISExempl.bat in the root of drive C. For
*      best effect, that file should include the following
*      lines:
*
*      PATH=C:\Windows
*      Win
*
\*-----*/

```

```

#define EXAMPLE_BAT "C:\\ISEXAMPL.BAT"
#define EXAMPLE_BAK "ISEXAMPL.BAK"

    STRING szPath;

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"
    function OnBegin()
    begin

        // Load the batch file to be edited.
        if (BatchFileLoad (EXAMPLE_BAT) < 0) then
            MessageBox ("Unable to load " + EXAMPLE_BAT+".", SEVERE);
            abort;
        endif;

        // Add a SET PATH command that appends the value of an existing
        // search path to C:\\EXAPP\\BIN.
        szPath = "C:\\EXAPP\\BIN;%PATH%";

        if (BatchAdd ("PATH", szPath, "PATH", AFTER) < 0) then
            MessageBox ("First call to BatchAdd failed", WARNING);
            abort;
        endif;

        // Add the line SET EXENV = C:\\OTHERAPP\\BIN. If the
        // environment variable EXENV already exists in the batch
        // file, the last SET EXENV statement is replaced.
        szPath = "C:\\OTHERAPP\\BIN";

        if (BatchAdd ("EXENV", szPath, "EXENV", REPLACE) < 0) then
            MessageBox ("Second call to BatchAdd failed", WARNING);
            abort;
        endif;

        // Add the command SHARE.EXE before the command WIN.
        if (BatchAdd ("", "SHARE.EXE", "WIN", BEFORE | COMMAND) < 0) then
            MessageBox ("Third call to BatchAdd failed", WARNING);
            abort;
        endif;

        // Save the updated file; back up the original file.
        if (BatchFileSave(EXAMPLE_BAK) < 0) then
            MessageBox ("Unable to save " + EXAMPLE_BAK + ".", SEVERE);
        else
            MessageBox ("Batch file saved. Backup created.", INFORMATION);
        endif;

    end;

```

The following example applies to:

## Basic MSI Installations

**Tip** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the BatchAdd function.
*
* This example script adds three statements to a batch file.
* First, it adds a PATH statement. Next, it adds a command to
* set the environment variable EXENV. Then it adds a command
* to launch SHARE.EXE, placing it before the existing command
* to start Windows. Finally, it backs up the original file
* and saves the edited file under its original name.
*
* If any of the calls to BatchAdd fails, the setup exits
* without saving changes to the batch file.
*
* Note: Before running this script, create a batch file
*       named ISEXAMPL.bat in the root of drive C. For
*       best effect, that file should include the following
*       lines:
*
*       PATH=C:\Windows
*       Win
*
\*-----*/

#define EXAMPLE_BAT "C:\\ISEXAMPL.BAT"
#define EXAMPLE_BAK "ISEXAMPL.BAK"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_BatchAdd(HWND);

function ExFn_BatchAdd(hMSI)
    STRING szPath;
begin

    // Load the batch file to be edited.
    if (BatchFileLoad (EXAMPLE_BAT) < 0) then
        MessageBox ("Unable to load " + EXAMPLE_BAT+".", SEVERE);
        abort;
    endif;

    // Add a SET PATH command that appends the value of an existing
    // search path to C:\EXAPP\BIN.
    szPath = "C:\\EXAPP\\BIN;%PATH%";

    if (BatchAdd ("PATH", szPath, "PATH", AFTER) < 0) then
```

```

        MessageBox ("First call to BatchAdd failed", WARNING);
        abort;
    endif;

    // Add the line SET EXENV = C:\OTHERAPP\BIN. If the
    // environment variable EXENV already exists in the batch
    // file, the last SET EXENV statement is replaced.
    szPath = "C:\\OTHERAPP\\BIN";

    if (BatchAdd ("EXENV", szPath, "EXENV", REPLACE) < 0) then
        MessageBox ("Second call to BatchAdd failed", WARNING);
        abort;
    endif;

    // Add the command SHARE.EXE before the command WIN.
    if (BatchAdd ("", "SHARE.EXE", "WIN", BEFORE | COMMAND) < 0) then
        MessageBox ("Third call to BatchAdd failed", WARNING);
        abort;
    endif;

    // Save the updated file; back up the original file.
    if (BatchFileSave(EXAMPLE_BAK) < 0) then
        MessageBox ("Unable to save " + EXAMPLE_BAK + ".", SEVERE);
    else
        MessageBox ("Batch file saved. Backup created.", INFORMATION);
    endif;

end;

```

## BatchDeleteEx

The **BatchDeleteEx** function deletes lines in a batch file that contain the value specified in szKey.

**Note** ▪ Before calling *BatchDeleteEx*, you must call *BatchFileLoad* to load the file to be modified into memory. After you modify the file, call *BatchFileSave* to save it to disk.

Do not mix the Ez batch file functions with the advanced batch file functions. After calling *BatchFileLoad*, you cannot use Ez batch file functions until you have called *BatchFileSave* to save the file.

### Syntax

```
BatchDeleteEx ( szKey, nOptions );
```

## Parameters

**Table 19** ▪ BatchDeleteEx Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>    | Specifies the reference keyword that identifies the line or lines to be deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>nOptions</b> | <p>Indicates whether szKey specifies an environment variable in a SET statement or a command. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li> <b>0</b>—Specifies that szKey is an environment variable in a SET statement. An environment variable is either a predefined identifier (such as PATH, COMSPEC, and LIB), or a user-defined identifier. For example, the following statement would be deleted if the value of szKey was "LIBPATH" and nOptions was set to 0:           <pre>SET LIBPATH=C:\Lang\Lib</pre> </li> <li> <b>COMMAND</b>—Specifies that szKey is either a DOS command or a program file name.           </li> </ul> |

## Return Values

**Table 20** ▪ BatchDeleteEx Return Values

| Return Value  | Description                                                              |
|---------------|--------------------------------------------------------------------------|
| <b>0</b>      | BatchDeleteEx successfully deleted lines containing the specified value. |
| <b>&lt; 0</b> | BatchFileLoad was unable to delete lines containing the specified value. |

## BatchDeleteEx Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
```

```

* Demonstrates the BatchDeleteEx function.
*
* This example script deletes lines from a batch file. First,
* it calls BatchFileLoad to load the file. Next, it deletes
* all lines with a PATH command. Then it deletes all lines
* that reference MyApp.exe (for example, C:\MyApps\MyApp.exe).
* Finally, it backs up the original file and saves the
* edited file under its original name.
*
* Note: Before running this script, create a batch file
*       named ISExempl.bat in the root of drive C. For
*       best effect, that file should include the
*       following lines:
*
*       SET PATH=C:\Windows
*       C:\MyApps\MyApp.exe
*
\*-----*/

#define EXAMPLE_BAT "C:\\ISExempl.bat"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_BatchDeleteEx(HWND);

function ExFn_BatchDeleteEx(hMSI)
    STRING szBackupFile;
begin

    // Load or create the batch file to be edited.
    if (BatchFileLoad (EXAMPLE_BAT) < 0) then
        MessageBox ("Unable to load " + EXAMPLE_BAT + ".", SEVERE);
        abort;
    endif;

    // Delete all SET PATH= commands.
    BatchDeleteEx ("PATH", 0);

    // Delete all lines with references to MyApp.exe.
    BatchDeleteEx ("MyApp.exe", COMMAND);

    // Save the edited batch file.
    if (BatchFileSave("Example.bak") < 0) then
        MessageBox ("Unable to save " + EXAMPLE_BAT + ".", SEVERE);
    else
        MessageBox ("Batch file saved.", INFORMATION);
    endif;

end;

```

# BatchFileLoad

The **BatchFileLoad** function loads a copy of the specified batch file into memory so that other advanced batch file functions can be called to operate on the file. Specify the name of the batch file you want to edit in `szBatchFile` or pass a null string ("" ) in `szBatchFile` to edit the default batch file, which is set initially by InstallShield to the bootup `Autoexec.bat` file used by the system.

Note that you can call `BatchFileLoad` to create a new batch file. To do so, pass in `szBatchFile` the name of a file that does not exist. Then call other batch functions to edit the new file. Finally, call [BatchFileSave](#) to save the new file to disk.

---

**Note** ▪ Before using any of the advanced batch file functions, you must call `BatchFileLoad` to load the file to be modified into memory. After you modify the file, call `BatchFileSave` to save it to disk. To obtain the fully qualified file name of the batch file that will be used by default in the installation script, call [BatchGetFileName](#). To specify a different batch file to be used by default in the installation script, call [BatchSetFileName](#).

Do not mix the Ez batch file functions with the advanced batch file functions. After calling `BatchFileLoad`, you cannot use Ez batch file functions until you have called `BatchFileSave` to save the file.

## Syntax

```
BatchFileLoad ( szBatchFile );
```

## Parameters

**Table 21** ▪ BatchFileLoad Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szBatchFile</b> | <p>Specifies the fully qualified name of the batch file to load into memory. To load the current default batch file, pass a null string (""). If you specify a file in this parameter, that file becomes the default batch file. After calling this function, you can use all of the advanced batch file functions to manipulate this file.</p> <p>To create a new batch file with BatchFileLoad, pass in szBatchFile the name of a file that does not exist. Then call other batch functions to edit the new file.</p> |

## Return Values

**Table 22** ▪ BatchFileLoad Return Values

| Return Value  | Description                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | BatchFileLoad successfully initialized the batch file buffer. If szConfigFile specified an existing batch file, the file was loaded into the buffer; otherwise, an empty buffer was created. |
| <b>&lt; 0</b> | BatchFileLoad was unable to initialize the batch file buffer.                                                                                                                                |

## BatchFileLoad Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the BatchFileLoad and BatchFileSave functions.
*
* This example script shows how to open a batch file for
* editing, how to create a backup of the original file, and
* how to save and close the edited file.
*
```

```

* To demonstrate how the file backup feature of BatchFileSave
* prevents the overwriting of existing files, this script loads
* and saves two different batch files. The first batch file is
* backed up with a specific file name. The second is backed up
* with a wildcard extension so that BatchFileSave will
* generate a unique file extension consisting of three digits.
*
* Note: Before running this script, create two batch files
*       (ISExamp1.bat and ISExamp2.bat) in the root of drive C.
*       For best effect, you should delete or move any other
*       files named ISExamp1.* or ISExamp2.*.
*
\*-----*/

// Names of batch files and backup files used in this example.
#define EXAMPLE1 "ISExamp1"
#define EXAMPLE2 "ISExamp2"

// Full names of batch files.
#define EXAMPLE1_BAT "C:\\\" + EXAMPLE1 + ".bat"
#define EXAMPLE2_BAT "C:\\\" + EXAMPLE2 + ".bat"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_BatchFileLoad(HWND);

function ExFn_BatchFileLoad(hMSI)
begin
    // Load EXAMPLE1_BAT.
    if (BatchFileLoad (EXAMPLE1_BAT) < 0) then
        MessageBox ("Unable to load " + EXAMPLE1_BAT + ".", SEVERE);
        abort;
    endif;

    // Use other batch file functions here to edit the first file.
    // Back up the original file with the extension "bak"; save the
    // edited file under its original name. If ISExamp1.bak already
    // exists, BatchFileSave will generate a numbered extension.
    if (BatchFileSave (EXAMPLE1 + ".bak") < 0) then
        MessageBox ("Unable to save " + EXAMPLE1_BAT + ".", SEVERE);
        abort;
    else
        MessageBox (EXAMPLE1_BAT + " saved.", INFORMATION);
    endif;

    // Load EXAMPLE2_BAT.
    if (BatchFileLoad (EXAMPLE2_BAT) < 0) then
        MessageBox ("Unable to load " + EXAMPLE2_BAT + ".", SEVERE);
        abort;
    endif;

    // Use other batch file functions here to edit the second file.
    // Back up the original batch file with a numbered extension
    // and save the edited file under its original name.

```

```

if (BatchFileSave (EXAMPLE2 + ".*") < 0) then
    MessageBox ("Unable to save " + EXAMPLE2_BAT + ".", SEVERE);
    abort;
else
    MessageBox (EXAMPLE2_BAT + " saved.", INFORMATION);
endif;

end;

```

## BatchFileSave

The **BatchFileSave** function saves to disk a batch file that has been loaded into memory with the function **BatchFileLoad**. The file is saved under its original name. If a file name is specified in szBackupFile, the original file is renamed with that file name before the edited file is written to disk. If szBackupFile contains a null string (""), the original file is replaced with the modified file. If you do not call BatchFileSave when you are finished modifying a batch file with advanced batch file functions, all modifications will be lost.

---

**Note** ▪ Do not mix the Ez batch file functions with the advanced batch file functions. After calling BatchFileLoad, you cannot use Ez batch file functions until you have called BatchFileSave to save the file.

### Syntax

```
BatchFileSave ( szBackupFile );
```

## Parameters

**Table 23** ▪ BatchFileSave Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szBackupFile</b> | <p>Specifies whether a backup copy of the original file as it existed before editing should be saved.</p> <ul style="list-style-type: none"> <li>• If no backup file should be created, specify a null string in this parameter.</li> <li>• If the original file should be backed up with a specific name, pass that file name in this parameter. The file name must be unqualified (that is, do not specify a drive and/or path). Note that if a file with the specified name already exists, BatchFileSave will generate a unique file extension, as described in the next bullet item.</li> <li>• If the original file should be backed up with an installation-generated file extension, specify the wildcard character "*" as the file extension (for example, "Batch.*"). The installation will then assign a numeric value, starting at 001, as the extension. If a file already exists with that extension, the extension's value will be increased by one until a unique file name is created.</li> </ul> <p>Once the backup has been created, InstallShield stores the backup file name in the system variable <b>INFOFILENAME</b>.</p> <div>  <p><b>Note</b> - If the batch file specified by the last call to BatchFileLoad did not exist, then the backup file is identical to the batch file created by the call to BatchFileSave. If szBackupFile specifies the name of the original batch file, then a backup file is not created.</p> </div> |

## Return Values

**Table 24** ▪ BatchFileSave Return Values

| Return Value | Description                                                        |
|--------------|--------------------------------------------------------------------|
| 0            | BatchFileSave successfully saved the batch file in memory to disk. |
| < 0          | BatchFileSave was unable to save the batch file to disk.           |

## BatchFileSave Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the BatchFileLoad and BatchFileSave functions.
*
* This example script shows how to open a batch file for
* editing, how to create a backup of the original file, and
* how to save and close the edited file.
*
* To demonstrate how the file backup feature of BatchFileSave
* prevents the overwriting of existing files, this script loads
* and saves two different batch files. The first batch file is
* backed up with a specific file name. The second is backed up
* with a wildcard extension so that BatchFileSave will
* generate a unique file extension consisting of three digits.
*
* Note: Before running this script, create two batch files
*       (ISExamp1.bat and ISExamp2.bat) in the root of drive C.
*       For best effect, you should delete or move any other
*       files named ISExamp1.* or ISExamp2.*.
*
\*-----*/

    // Back up the original batch file with a numbered extension
    // and save the edited file under its original name.
    if (BatchFileSave (EXAMPLE2 + ".*") < 0) then
        MessageBox ("Unable to save " + EXAMPLE2_BAT + ".", SEVERE);
        abort;
    else
        MessageBox (EXAMPLE2_BAT + " saved.", INFORMATION);
    endif;

end;

```

## BatchFind

The **BatchFind** function searches a batch file for one or more occurrences of the reference key specified in szRefKey. If you specify the constant RESTART in nOptions, the first occurrence of the reference key is returned. To find the next occurrence of szRefKey, call this function repeatedly with nOptions set to CONTINUE.

**Note** - Before calling *BatchFind*, you must call *BatchFileLoad* to load the file to be modified into memory. After you modify the file, call *BatchFileSave* to save it to disk.

Do not mix the Ez batch file functions with the advanced batch file functions. After calling *BatchFileLoad*, you cannot use Ez batch file functions until you have called *BatchFileSave* to save the file.

## Syntax

```
BatchFind ( szRefKey, svResult, nOptions );
```

## Parameters

**Table 25** ▪ BatchFind Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szRefKey</b> | Specifies the reference key to search for. The reference key can be an environment variable, a DOS command, or a program name. If the reference key is a file name and you do not specify a file extension, the function returns all reference keys with the base file name. For example, if you specify Win.com, the search looks for this reference key only. If you specify Win, the reference keys Win.exe, Win.dll, Win.sys, and so on will be returned if they exist in the batch file.                                                                                                                        |
| <b>svResult</b> | Specifies the value of the reference key that was found in the batch file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>nOptions</b> | <p>Specifies where to start the search; pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>CONTINUE</b>—Starts the search from the current position in the batch file.</li> <li>● <b>RESTART</b>—Starts the search from the beginning of the batch file.</li> </ul> <p>When the reference key you are searching for is a DOS command or program name (not an environment variable), use the OR operator to combine the constant COMMAND with CONTINUE or RESTART, as shown below:</p> <pre>BatchFind ("SCAN.EXE", svResult, COMMAND   RESTART);</pre> |

## Return Values

**Table 26** ▪ BatchFind Return Values

| Return Value  | Description                                                                     |
|---------------|---------------------------------------------------------------------------------|
| <b>0</b>      | BatchFind successfully found the value of szRefKey and returned it in svResult. |
| <b>&lt; 0</b> | BatchFind was unable to find the value of szRefKey and return it in svResult.   |

## BatchFind Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the BatchFind function.
*
* This example script searches a batch file and reports whether
* or not the file includes a command that references SHARE.EXE.
* It then finds and displays all PATH and SET PATH statements.
*
* Note: Before running this script, create a batch file
*       named ISExempl.bat and store it in the root of
*       drive C. The batch file should include a command
*       to launch Share.exe, and it should contain at least
*       one PATH or SET PATH= statement.
*
\*-----*/

#define TARGET_BATCH "C:\\ISExempl.bat"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_BatchFind(HWND);

function ExFn_BatchFind(hMSI)
    STRING svResult;
    NUMBER nResult;
begin

    // Load the target batch file.
    if (BatchFileLoad (TARGET_BATCH ) < 0) then
        MessageBox ("Unable to load " + TARGET_BATCH + ".", SEVERE);
        abort;
    endif;

    // Check for a SHARE.EXE command.
    nResult = BatchFind ("SHARE.EXE", svResult, COMMAND);

    if (nResult < 0) then
        MessageBox ("SHARE.EXE command not found.", WARNING);
    else
        MessageBox ("SHARE.EXE command found.", INFORMATION);
    endif;

    // Find the first PATH or SET PATH= statement. Pass RESTART in
    // the third parameter to begin searching at the top of the file.
    nResult = BatchFind ("PATH", svResult, RESTART);
```

```

if (nResult < 0) then
    MsgBox ("PATH command not found.", WARNING);
else

    // Loop while PATH commands are found.
    while (nResult = 0)
        MsgBox (svResult, INFORMATION);

        // Find the next PATH command. Pass CONTINUE in the
        // third parameter to continue the search with the
        // statement that follows the last match.
        nResult = BatchFind ("PATH", svResult, CONTINUE);
    endwhile;

    MsgBox ("No more PATH commands.", WARNING);

endif;

end;

```

## BatchGetFileName

The **BatchGetFileName** function retrieves the fully qualified name of the default batch file, which is set initially by InstallShield to the bootup Autoexec.bat file used by the system. To specify a different batch file to be used by default in the script, call [BatchSetFileName](#).

---

**Note** ▪ Do not mix the Ez batch file functions with the advanced batch file functions. After calling [BatchFileLoad](#), you cannot use Ez batch file functions until you have called [BatchFileSave](#) to save the file.

### Syntax

```
BatchGetFileName ( svFileName );
```

## Parameters

**Table 27** ▪ BatchGetFileName Parameters

| Parameter         | Description                                                               |
|-------------------|---------------------------------------------------------------------------|
| <b>svFileName</b> | Returns the fully qualified name of the default batch file in svFileName. |

## Return Values

**Table 28** ▪ BatchGetFileName Return Values

| Return Value  | Description                                                                                 |
|---------------|---------------------------------------------------------------------------------------------|
| <b>0</b>      | BatchGetFileName successfully retrieved the fully qualified name of the default batch file. |
| <b>&lt; 0</b> | BatchGetFileName was unable to retrieve the fully qualified name of the default batch file. |

## BatchGetFileName Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the BatchGetFileName and BatchSetFileName
 * functions.
 *
 * This example script retrieves the fully qualified name of the
 * default batch file, which initially is the Autoexec.bat file
 * on the boot drive. It then makes C:\ISExempl.bat the default
 * batch file. Finally, it retrieves the name of the default
 * batch file again to show that it has been changed.
 *
 \*-----*/

#define DEFAULT_BATCH_FILE "C:\\ISExempl.bat"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_BatchGetFileName(HWND);

function ExFn_BatchGetFileName(hMSI)
    STRING svFilename;

```

```

begin

    // Get the name of the default batch file.
    if (BatchGetFileName (svFilename) < 0) then
        // Report the error; then abort.
        MessageBox ("First call to BatchGetFileName failed.", SEVERE);
        abort;
    else
        // Display the name of the default batch file.
        MessageBox ("The default batch file is " + svFilename + ".",
                    INFORMATION);
    endif;

    // Make C:\ISExempl.bat the default batch file.
    if (BatchSetFileName(DEFAULT_BATCH_FILE) < 0) then
        // Report the error.
        MessageBox ("Unable to set new default batch file.", SEVERE);
    else

        // Verify that the default batch file has been changed.
        if (BatchGetFileName(svFilename) < 0) then
            // Handle an error.
            MessageBox ("Second call to BatchGetFileName failed.", SEVERE);
        else
            // Display the name of the default batch file.
            MessageBox ("Now the default batch file is " + svFilename + ".",
                        INFORMATION);
        endif;
    endif;

endif;

end;

```

## BatchMoveEx

The **BatchMoveEx** function moves the line specified by szMove from one location to another in a batch file. The parameter nOptions specifies whether to position the line at the beginning or end of the batch file, or before or after the line specified by szRefKey.

**Note** ▪ Before calling *BatchMoveEx*, you must call *BatchFileLoad* to load the file to be modified into memory. After you modify the file, call *BatchFileSave* to save it to disk.

Do not mix the Ez batch file functions with the advanced batch file functions. After calling *BatchFileLoad*, you cannot use Ez batch file functions until you have called *BatchFileSave* to save the file.

### Syntax

```
BatchMoveEx ( szMove, szRefKey, nOptions, nMoveOption );
```

## Parameters

**Table 29** ▪ BatchMoveEx Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMove</b>      | Specifies the reference key that identifies the line to be moved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szRefKey</b>    | Specifies the key that identifies the reference line used to position the line being moved. If szRefKey is a null string (""), the line specified by szMove is moved to the beginning or end of the file, depending on the value of nOptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>nOptions</b>    | <p>Specifies where to move the line. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>BEFORE</b>—The line specified by szMove is moved before the line containing the reference key in szRefKey. If szRefKey is a null string (""), the line specified by szMove is moved to the beginning of the file.</li> <li>● <b>AFTER</b>—The line specified by szMove is moved after the line containing the reference key in szRefKey. If szRefKey is a null string (""), the line specified by szMove is moved to the end of the file.</li> </ul> <p>When the reference key you are searching for is a DOS command or program name (not an environment variable), use the OR operator to combine the constant COMMAND with BEFORE or AFTER, as shown below:</p> <pre>BatchMoveEx ("PATH", "SCAN.EXE", BEFORE   COMMAND, 0);</pre> |
| <b>nMoveOption</b> | <p>Specifies whether szMove is a command or an environment variable. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>0</b>—Specifies that szMove is an environment variable.</li> <li>● <b>COMMAND</b>—Specifies that szMove is a command.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Return Values

**Table 30** ▪ BatchMoveEx Return Values

| Return Value | Description                                                          |
|--------------|----------------------------------------------------------------------|
| 0            | BatchMoveEx successfully moved the specified line in the batch file. |
| < 0          | BatchMoveEx was unable to move the line in the batch file.           |

## BatchMoveEx Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the BatchMoveEx function.
*
* This example script moves lines within a batch file. First,
* it calls BatchFileLoad to load the file. Next, it moves
* the first PATH command to the end of the file. Then it
* moves the first statement that references Share.exe ahead
* of the statement that launches Windows.
*
* Note: Before running this script, create a batch file
*       named ISExempl.bat in the root of drive C. For
*       best effect, the first line in that file should
*       be a PATH command; the next statement should
*       launch Windows; the last statement should execute
*       Share.exe.
*
\*-----*/

#define TARGET_BATCH "C:\\ISExempl.bat"
#define BACKUP_BATCH "ISExempl.bak"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_BatchMoveEx(HWND);

function ExFn_BatchMoveEx(hMSI)
begin
    // Load the batch file to be edited.
    if BatchFileLoad (TARGET_BATCH) < 0 then
        MessageBox ("Unable to load " + TARGET_BATCH+".", SEVERE);
```

```

        abort;
    endif;

    // Move the PATH statement to the end of the file.
    if (BatchMoveEx ("PATH", "", AFTER, 0) < 0) then
        MessageBox ("Unable to move PATH statement.", SEVERE);
    else
        MessageBox ("PATH statement moved to end of file.", INFORMATION);
    endif;

    else
        MessageBox ("Batch file saved. Backup created.", INFORMATION);
    endif;

end;

```

## BatchSetFileName

The **BatchSetFileName** function specifies the name of the batch file to be used by Ez batch file functions and by **BatchFileLoad** when it is called with a null string ("" ) as its parameter. In InstallScript, this file is referred to as the default batch file. During installation initialization, the default batch file is set to the bootup Autoexec.bat file used by the system.

BatchSetFileName simply assigns the name of the default batch file. It does not verify that the specified file exists, nor does it load the file into memory. Because of this, the function will succeed even if the file name is invalid or the specified file does not exist. An invalid file name causes subsequent Ez batch file and advanced batch file functions to fail.

---

**Note** ▪ Do not mix the Ez batch file functions with the advanced batch file functions. After calling **BatchFileLoad**, you cannot use Ez batch file functions until you have called **BatchFileSave** to save the file.

### Syntax

```
BatchSetFileName ( szBatchFile );
```

## Parameters

**Table 31** ▪ BatchSetFileName Parameters

| Parameter          | Description                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------|
| <b>szBatchFile</b> | Specifies the fully qualified name of the batch file to be used by default in the installation script. |

## Return Values

**Table 32** ▪ BatchSetFileName Return Values

| Return Value  | Description                                                                     |
|---------------|---------------------------------------------------------------------------------|
| <b>0</b>      | BatchSetFileName successfully set the specified file as the default batch file. |
| <b>&lt; 0</b> | BatchSetFileName was unable to set the file as the default batch file.          |

## BatchSetFileName Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the BatchGetFileName and BatchSetFileName
* functions.
*
* This example script retrieves the fully qualified name of the
* default batch file, which initially is the Autoexec.bat file
* on the boot drive. It then makes C:\ISExempl.bat the default
* batch file. Finally, it retrieves the name of the default
* batch file again to show that it has been changed.
*
\*-----*/

#define DEFAULT_BATCH_FILE "C:\\ISExempl.bat"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_BatchSetFileName(HWND);

function ExFn_BatchSetFileName(hMSI)

```

```

    STRING svFilename;
begin

    // Get the name of the default batch file.
    if (BatchGetFileName (svFilename) < 0) then
        // Report the error; then abort.
        MessageBox ("First call to BatchGetFileName failed.", SEVERE);
        abort;
    else
        // Display the name of the default batch file.
        MessageBox ("The default batch file is " + svFilename + ".",
                    INFORMATION);
    endif;

    // Make C:\ISExempl.bat the default batch file.
    if (BatchSetFileName(DEFAULT_BATCH_FILE) < 0) then
        // Report the error.
        MessageBox ("Unable to set new default batch file.", SEVERE);
    else

        // Verify that the default batch file has been changed.
        if (BatchGetFileName(svFilename) < 0) then
            // Handle an error.
            MessageBox ("Second call to BatchGetFileName failed.", SEVERE);
        else
            // Display the name of the default batch file.
            MessageBox ("Now the default batch file is " + svFilename + ".",
                        INFORMATION);
        endif;
    endif;

end;

```

## CalculateAndAddFileCost

The **CalculateAndAddFileCost** function determines the cost of the specified file and adds it to the current value of nvCostHigh and/or nvCostLow. This allows you to calculate and add up the cost of multiple files by calling the function multiple times in a loop. Set nvCostHigh and nvCostLow to zero before calling the function to determine the cost of a single file. This function is typically used when you need to determine the cost of file of a known size so this cost can then be passed to FeatureAddCost.

**Note** ▪ Note that this function does not actually set any information to be used directly by the installation. You must call FeatureAddCost (as appropriate) after calling this function to add the additional cost to an existing feature.

### Syntax

```
CalculateAndAddFileCost ( nFileSizeHigh, nFileSizeLow, szTargetDir, nClusterSize, nvCostHigh, nvCostLow
);
```

## Parameters

**Table 33** ▪ CalculateAndAddFileCost Parameters

| Parameter            | Description                                                                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nFileSizeHigh</b> | The upper 31 bits of the file size (in bytes). Typically retrieved using GetFileInfo.                                                                                              |
| <b>nFileSizeLow</b>  | The lower 31 bits of the file size (in bytes). Typically retrieved using GetFileInfo.                                                                                              |
| <b>szTargetDir</b>   | If nClusterSize is 0, the target folder for the file. This path is used to determine the cluster size of the target drive. If nClusterSize is non-zero, this parameter is ignored. |
| <b>nClusterSize</b>  | Specifies the cluster size of the target drive. If this parameter is 0, the function determines this information from szTargetDir.                                                 |
| <b>nvCostHigh</b>    | The upper 31 bits of the installation cost (in bytes) of this file is added to the current value of this variable.                                                                 |
| <b>nvCostLow</b>     | The lower 31 bits of the installation cost (in bytes) of this file is added to the current value of this variable.                                                                 |

## Return Values

**Table 34** ▪ CalculateAndAddFileCost Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# CallDLLFx

**Tip** ▪ The **CallDLLFx** function is supported only for compatibility with scripts created in previous versions of InstallShield. Consider using the more flexible method described in *Calling a .dll File Function* instead of using the **CallDLLFx** function.

The **CallDLLFx** function calls a function within a specified .dll file.

## Syntax

```
CallDLLFx ( szDLL, szFunction, lvValue, svValue );
```

The function called must use the following fixed definition, where `hwnd` is the main window handle for the main InstallShield window:

```
LONG WINAPI YourFunction (HWND hwnd, LPLONG lpIValue, LPSTR lpszValue);
```

## Parameters

**Table 35** • CallDLLFx Parameters

| Parameter         | Description                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------|
| <b>szDLL</b>      | Specifies the fully qualified file name of the .dll file that contains the function to execute. |
| <b>szFunction</b> | Specifies the name of the function in the .dll file specified in <code>szDLL</code> .           |
| <b>lvValue</b>    | Specifies a long integer variable to pass by reference to the .dll function.                    |
| <b>svValue</b>    | Specifies a string variable to pass to the .dll function.                                       |

## Return Values

The `CallDLLFx` function returns a long integer from the function in the .dll file.

## CallDLLFx Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CallDLLFx function.
*
* Note: This script requires that the constant DLL_FILE be set
*       to the fully qualified name of a .dll file that contains
*       a function called Test whose format matches the
*       prototype declaration below. That function should
*       modify the values passed in the third and fourth
*       parameters and then return those values in the same
*       parameters.
*
*-----*/
```

```

#define ID_NEXT 1 // Return value if user clicks 'Next' button
#define ID_CANCEL 2 // Return value if user clicks 'Cancel' button
#define ID_BACK 4 // Return value if user clicks 'Back' button

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_CallDLLFx(HWND);

function ExFn_CallDLLFx(hMSI)
    INT nValue, nResult;
    STRING szString, szResult, szDLL, szValue, szReturn;
begin

    // Set the setup window title.
    SetTitle ("CallDLLFx Example", 18, WHITE);

    // Set the location of the .dll.
    szDLL = SUPPORTDIR ^ "MYDLL.DLL";

    // Set up parameters for call to .dll function.
    nValue = 3000;
    szString = "Test String";

    // Show inputs to users.
    sprintfBox (INFORMATION, "", "Before - nValue: %i , szString: %s",
    nValue, szString);

    // Call .dll function; pass by value.
    nResult = CallDLLFx(szDLL, "Test", nValue, szString);

    // Show values returned by .dll function.
    sprintfBox(INFORMATION, "", "Returned - nValue: %i , szString: %s",
    nValue, szString);

end;

```

## ChangeDirectory

The **ChangeDirectory** function sets the current directory.

**Note** ▪ After you call *ChangeDirectory* to make a specified directory the current directory, that directory cannot be deleted. Before you can delete that directory, you must call *ChangeDirectory* again to set a different current directory.

### Syntax

```
ChangeDirectory ( szPath );
```

## Parameters

**Table 36** ▪ ChangeDirectory Parameters

| Parameter                                                                                                                                                                                                                                                                                                                                                                                                                                             | Description                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPath</b>                                                                                                                                                                                                                                                                                                                                                                                                                                         | Specifies the name of the directory to set as the current directory. That name can be either a fully qualified directory name or a UNC path; it must not include a trailing backslash. If necessary, call <a href="#">StrRemoveLastSlash</a> before calling ChangeDirectory. |
|  <p><b>Note</b> ▪ When you are specifying a file in your script, always specify the full path (using the appropriate InstallShield system variable, for example, SRCDIR) rather than depend on the current folder having the appropriate value. The script internally executes code that can change the current folder, so its value may not be what you expect.</p> |                                                                                                                                                                                                                                                                              |

## Return Values

**Table 37** ▪ ChangeDirectory Return Values

| Return Value  | Description                                                                         |
|---------------|-------------------------------------------------------------------------------------|
| <b>0</b>      | ChangeDirectory successfully set the specified directory as the current directory.  |
| <b>&lt; 0</b> | ChangeDirectory was unable to set the specified directory as the current directory. |

## ChangeDirectory Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ChangeDirectory function.
*
* This example script makes the Windows folder the current
* directory and then launches NotePad to display the file

```

```

* Readme.txt.
*
\*-----*/
// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ChangeDirectory(HWND);

function ExFn_ChangeDirectory(hMSI)
begin

// Make the Windows folder the default directory. Note that
// the InstallShield system variable WINDIR points
// to the Windows folder.

ChangeDirectory (WINDIR);
// Launch Notepad to view the Windows Readme.txt file.
LaunchApp ("Notepad.exe", "Readme.txt" );

end;

```

## CharReplace

The **CharReplace** function replaces all instances of the character cFind with cReplace in the string svString, except characters whose string index is less than nStart. The string index of the first character in a string is 0.

### Syntax

```
CharReplace ( svString, cFind, cReplace, nStart );
```

## Parameters

**Table 38** ▪ CharReplace Parameters

| Parameter       | Description                                                                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svString</b> | Specifies the string whose characters will be replaced, and returns the modified string.                                                                                                                                      |
| <b>cFind</b>    | Specifies the character to be replaced. Use the <a href="#">STRTOCHAR</a> function to specify a char literal as cFind; for example:<br><br>CharReplace( svString, STRTOCHAR('a'), STRTOCHAR('e'), nStart );                   |
| <b>cReplace</b> | Specifies the character to replace cFind. Use the <a href="#">STRTOCHAR</a> function to specify a char literal as cReplace; for example:<br><br>CharReplace( svString, STRTOCHAR('a'), STRTOCHAR('e'), nStart );              |
| <b>nStart</b>   | Specifies the string index at which to begin searching for cFind. Note that the string index of the first character in svString is 0 (zero). If you want to replace all instances of cFind in svString, specify 0 for nStart. |

## Return Values

**Table 39** ▪ CharReplace Return Values

| Return Value              | Description                                            |
|---------------------------|--------------------------------------------------------|
| <b>X</b>                  | The total number of replacements of cFind by cReplace. |
| <b>&lt; ISERR_SUCCESS</b> | The function failed to replace the characters.         |

## Additional Information

cFind or cReplace can be null characters ('\0'). To handle null-delimited strings, specify cFind or cReplace as StrToChar('\0'); note that the constant NULL is 0, not '\0', and cannot be used to specify the null character. When cFind or cReplace is '\0', CharReplace automatically sets the last two characters of the string buffer to '\0' before returning; therefore, the size of the string (which should be set explicitly) should be at least the number of characters to be stored plus two.

## CharReplace Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
//-----
//
// InstallScript Example Script
```

```
//
// Demonstrates the CharReplace function.
//
// This sample shows a sample path string before and after replacing
// every backslash character with a forward slash.
//
//-----

function OnBegin( )
    STRING path_to_convert;
begin

    // example path to convert
    path_to_convert = FOLDER_COMMON_APPDATA;

    MessageBox("Path before conversion: " + path_to_convert,
        INFORMATION);

    // replace backslashes with forward slashes
    CharReplace(path_to_convert,
        STRTOCHAR('\\'), STRTOCHAR('/'), 0);

    MessageBox("Path after conversion: " + path_to_convert,
        INFORMATION);

end;
```

## CloseFile

The **CloseFile** function closes a file that has been opened with a call to `OpenFile`. You cannot read from or write to a file after you close it.

### Syntax

```
CloseFile ( nvFileHandle );
```

## Parameters

**Table 40** ▪ CloseFile Parameters

| Parameter           | Description                                    |
|---------------------|------------------------------------------------|
| <b>nvFileHandle</b> | Specifies the handle of the file to be closed. |

## Return Values

**Table 41** ▪ CloseFile Return Values

| Return Value  | Description                                               |
|---------------|-----------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully closed the file. |
| <b>&lt; 0</b> | Indicates that the function was unable to close the file. |

## CloseFile Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the OpenFile and CloseFile functions.
*
* OpenFile is called to open a file, which is then read into
* a list. The file is then closed and the list is displayed.
*
* Note: Before running this script, set the preprocessor
* constants so that they reference an existing file
* in an existing directory.
*
\*-----*/

#define EXAMPLE_FILE "Readme.txt"
#define EXAMPLE_DIR "C:\\Windows"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_CloseFile(HWND);

function ExFn_CloseFile(hMSI)
    STRING svLine;
```

```

    NUMBER  nvFileHandle;
    LIST    listID;
begin

    // Set the file mode to normal.
    OpenFileMode (FILE_MODE_NORMAL);

    // Open the text file.
    if (OpenFile (nvFileHandle, EXAMPLE_DIR, EXAMPLE_FILE) < 0) then
        MessageBox ("OpenFile failed.", SEVERE);
        abort;
    endif;

    // Create an empty string list.
    listID = ListCreate (STRINGLIST);

    // Read lines from the text file into the string list.
    while GetLine (nvFileHandle, svLine) = 0
        ListAddString (listID, svLine, AFTER);
    endwhile;

    // Close the file.
    if (CloseFile (nvFileHandle) < 0) then
        MessageBox ("CloseFile failed.", SEVERE);
    endif;

    // Display the text that was read from the file.
    SdShowInfoList ("", "", listID);

end;

```

## CmdGetHwndDlg

The **CmdGetHwndDlg** function retrieves the window handle of the dialog identified by szDialogName. The dialog already must have been defined with **EzDefineDialog** or **DefineDialog** and initialized by calling **WaitOnDialog**.

**CmdGetHwndDlg** is typically called in the DLG\_INIT routine for a custom dialog. The handle of the dialog is assigned to a HWND variable to be used by other functions that need it.

---

**Note** ▪ When a dialog is initialized with the **WaitOnDialog** function, a window handle is assigned to it; that handle is associated with the dialog only until it is closed by a call to **EndDialog**. If you call **WaitOnDialog** to open a dialog that has been opened and closed previously in your script, you must call **CmdGetHwndDlg** again to get the new handle. The old handle is no longer valid.

### Syntax

```
CmdGetHwndDlg ( szDialogName );
```

## Parameters

**Table 42** ▪ CmdGetHwndDlg Parameters

| Parameter           | Description                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a dialog that has been defined with <b>EzDefineDialog</b> or <b>DefineDialog</b> . |

## Return Values

**Table 43** ▪ CmdGetHwndDlg Return Values

| Return Value  | Description                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt; 0</b> | The window handle of the dialog that was specified by szDialogName.                                                                                 |
| <b>&lt; 0</b> | <b>CmdGetHwndDlg</b> was unable to retrieve the handle. Verify that szDialogName refers to a dialog that has been properly defined and initialized. |

## CmdGetHwndDlg Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CmdGetHwndDlg function.
*
* This example displays a custom dialog. On initialization
* of the dialog, the script calls CmdGetHwndDlg to retrieve
* the dialog's window handle so that it can perform the
* following operations:
*
* -- Change the text of the window's title bar.
* -- Disable and enable buttons in the dialog.
* -- Send messages to maximize and restore the dialog window.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the
* built-in function SdBitmap. Because this dialog is stored in
* the file _isres.dll, which is already compressed in the
* installation, it can be used in a script as a custom dialog.
* Note that the script changes the static text of the dialog's
* Back and Next buttons to fit the requirements of the example.
*
*-----*/
```

```

// Dialog controls
#define RES_DIALOG_ID      12027    // ID of the custom dialog
#define RES_PBUT_RESTORE   1        // ID of dialog's Next button
#define RES_PBUT_CANCEL    9        // ID of dialog's Cancel button
#define RES_PBUT_MAXIMIZE  12       // ID of dialog's Back button

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_CmdGetHwndDlg(HWND);

function ExFn_CmdGetHwndDlg(hMSI)
    STRING szDialogName;
    NUMBER nResult, nCmdValue, hwndDlg;
    BOOL bDone;
    HWND hwndDlg;
begin

    // Specify a name to identify the custom dialog in
    // this installation.
    szDialogName = "CustomDialog";

    // Define the dialog. Pass a null string in the second parameter
    // to get the dialog from _ISUSER.DLL or _ISRES.DLL. Pass a null
    // string in the third parameter because the dialog is identified
    // by its ID in the fourth parameter.
    nResult = EzDefineDialog (szDialogName, "", "", RES_DIALOG_ID);

    if (nResult < 0) then
        // Report an error; then terminate.
        MessageBox ("Error in defining dialog", SEVERE);
        abort;
    endif;

    // Initialize the indicator used to control the loop.

                abort;
            case DLG_INIT:
                // Initialize the back, next, and cancel button enable/disable
                // states for this dialog and replace %P, %VS, %VI with
                // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
                // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
                hwndDlg = CmdGetHwndDlg(szDialogName);

```

```

SdGeneralInit(szDialogName, hwndDlg, 0, "");

// Set the static text of the buttons.
CtrlSetText (szDialogName, RES_PBUT_MAXIMIZE, "&Maximize");
CtrlSetText (szDialogName, RES_PBUT_RESTORE, "&Restore");

// Disable the Restore button using a call from WinSub.
_WinSubEnableControl (hwndDlg, RES_PBUT_RESTORE, 0);
case RES_PBUT_RESTORE:
    // Restore the window to its normal size.
    SendMessage (hwndDlg, WM_SYSCOMMAND, SC_RESTORE, 0);

    // Disable the Restore button using a call from WinSub.
    _WinSubEnableControl (hwndDlg, RES_PBUT_RESTORE, 0);

    // Enable the Maximize button using a call from WinSub.
    _WinSubEnableControl (hwndDlg, RES_PBUT_MAXIMIZE, 1);
case RES_PBUT_MAXIMIZE:
    // Maximize the dialog's window.
    SendMessage (hwndDlg, WM_SYSCOMMAND, SC_MAXIMIZE, 0);

    // Disable the Maximize button using a call from WinSub.
    _WinSubEnableControl (hwndDlg, RES_PBUT_MAXIMIZE, 0);

    // Enable the Restore button using a call from WinSub.
    _WinSubEnableControl (hwndDlg, RES_PBUT_RESTORE, 1);
case RES_PBUT_CANCEL:
    // The user clicked the Cancel button.
    Do (EXIT);
endswitch;

until bDone;

// Close the dialog.
EndDialog (szDialogName);

// Free the dialog from memory.
ReleaseDialog (szDialogName);

end;

```

## CoCreateObject

**Project** - This information applies to InstallScript projects.

The **CoCreateObject** function initializes the COM object named by szProgID and returns a reference that can be assigned to a variable of type OBJECT by using the set keyword.

### Syntax

```
CoCreateObject ( szProgID );
```

## Parameters

**Table 44** • CoCreateObject Parameters

| Parameter       | Description                                                   |
|-----------------|---------------------------------------------------------------|
| <b>szProgID</b> | Specifies the program ID of the COM object to be initialized. |

## Return Values

The reference can be assigned to a variable of type OBJECT by using the set keyword.

## Additional Information

- To check whether the object was initialized successfully, call the [IsObject](#) function.
- Any object variable can be released by setting the object variable to the value of NOTHING or reassigning the object with the **CoCreateObject**, **CoCreateObjectDotNet**, **CoGetObject**, or **DotNetCoCreateObject** functions. However, this does not automatically unload the library referenced by the object. You must call the Windows API, `CoFreeLibrary`, manually to free the library. Otherwise, the library remains loaded until the installation finishes. For more information, see [Extending Your Installation with COM Objects](#).

# CoCreateObjectDotNet

**Project** • The following project types support the **CoCreateObjectDotNet** function:

- *InstallScript*
- *InstallScript MSI*
- *Basic MSI with InstallScript custom actions*

The **CoCreateObjectDotNet** function has been deprecated. Calling this function is the same as calling the **DotNetCoCreateObject** function with a null string ("" ) for the `szAppDomain` parameter.

For more information, see [DotNetCoCreateObject](#).

# CoGetObject

**Project** • This information applies to *InstallScript* projects.

The **CoGetObject** function returns a reference to the specified COM object (as Visual Basic's `GetObject` function does); that reference can be assigned to a variable of type OBJECT by using the set keyword.

## Syntax

```
CoGetObject ( szFilename, szProgID );
```

## Parameters

**Table 45** • CoGetObject Parameters

| Parameter         | Description                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>szFilename</b> | Specifies the fully qualified name of the COM object. This parameter can be a null string ("") if szProgID is non-null. |
| <b>szProgID</b>   | Specifies the program ID of the COM object. This parameter can be a null string ("") if szFilename is non-null.         |

## Return Values

- A reference that can be assigned to a variable of type OBJECT by using the set keyword.
- Any object variable can be released by setting the object variable to the value of NOTHING or reassigning the object with the **CoCreateObject**, **CoCreateObjectDotNet**, **CoGetObject**, or **DotNetCoCreateObject** functions. However, this does not automatically unload the library referenced by the object. You must call the Windows API, **CoFreeLibrary**, manually to free the library. Otherwise, the library remains loaded until the installation finishes. For more information, see [Extending Your Installation with COM Objects](#).

## Additional Information

To check whether the object was initialized successfully, call the [IsObject](#) function.

## CoGetObject Example

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CoGetObject function.
*
* This example shows how to create a virtual
* directory on IIS server.
*
\*-----*/

#include "ifx.h"

#define VIRTUALDIR "My Virtual Dir"
#define VIRTUALDIRPATH "c:\inetpub\wwwroot\MyDir"

function OnBegin()
OBJECT objIIS_Root, objVirtDir;

begin

    set objIIS_Root = CoGetObject("IIS://localhost/W3SVC/1/Root", "");
    if (IsObject(objIIS_Root)) then
```

```

try
    set objVirtDir = objIIS_Root.Create("IISWebVirtualDir", VIRTUALDIR);
    if (IsObject(objVirtDir)) then
        objVirtDir.Path = VIRTUALDIRPATH;
        objVirtDir.AccessRead = TRUE;
        objVirtDir.AccessScript = TRUE;
        objVirtDir.SetInfo();
        objVirtDir.AppCreate(TRUE);
        objVirtDir.SetInfo();
    endif;
catch
    MsgBox("Unable to create Virtual Directory.", INFORMATION);
endcatch;
endif;

end;

```

## ConfigAdd

The **ConfigAdd** function adds a statement to the system configuration file that has been loaded into memory with **ConfigFileLoad**. You can specify the position of the statement relative to a reference key, or you can add the statement as the first or last line of the file. You can also replace an existing line in the file.

---

**Note** ▪ Before calling *ConfigAdd*, you must first call *ConfigFileLoad* to load the system configuration file into memory. After you edit the file, call *ConfigFileSave* to save the file.

Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling *ConfigFileLoad*, you cannot use the Ez configuration file functions until you call *ConfigFileSave* to save your changes.

### Syntax

```
ConfigAdd ( szKey, szValue, szRefKey, nOptions );
```

## Parameters

**Table 46** ▪ ConfigAdd Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>    | Specifies the keyword in the statement that is being added to the system configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>szValue</b>  | Specifies the value of the keyword that is being added to the system configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>szRefKey</b> | Specifies the reference key relative to which you are adding szKey in the system configuration file. If you pass a null string ("") in this parameter, the line is added as the first or last line in the file, depending on which predefined constant is passed in nOptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>nOptions</b> | <p>Specifies whether the line is to be added before or after the line containing the reference key, or whether the line replaces an existing line. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>BEFORE</b>—The statement is added before the line containing szRefKey. If szRefKey is a null string (""), the statement is added as the first line of the file.</li> <li>● <b>AFTER</b>—The statement is added after the line containing szRefKey. If szRefKey is a null string (""), the statement is added as the last line of the file.</li> <li>● <b>REPLACE</b>—The statement replaces an existing line in the file. If multiple lines with same key exist, only the last line is replaced. If a line to be replaced does not exist in the file, the new line is added as the last line of the file.</li> </ul> |

## Return Values

**Table 47** ▪ ConfigAdd Return Values

| Return Value  | Description                                                                            |
|---------------|----------------------------------------------------------------------------------------|
| <b>0</b>      | ConfigAdd successfully added the statement to the specified system configuration file. |
| <b>&lt; 0</b> | ConfigAdd was unable to add the statement to the specified system configuration file.  |

## Additional Information

When the ConfigAdd function replaces a line in a system configuration file, it compares the reference keys in the

two lines. A reference key is a substring that identifies the line. For example, in the following statement, the reference key is Kybrd.drv.

```
DEVICE=C:\Windows\System\Kybrd.drv /1024 /C:345
```

In the next statement, the reference key is PATH:

```
SET PATH=C:\Windows;C:\Windows\System
```

## ConfigAdd Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ConfigAdd function.
*
* This example script adds two statements to a configuration
* file. First, it calls ConfigFileLoad to load the file for
* editing. Next, it adds a DEVICE statement. Then it adds a
* DEVICEHIGH statement. Finally, it backs up the original file
* and saves the edited file.
*
* Note: Before running this script, create a configuration
*       file named ISExempl.sys in the root of drive C.
*       That file should include the following lines:
*
*       DEVICE=C:\Exapp\Exapp.sys
*       DEVICE=C:\Otherapp.exe
*
\*-----*/

#define EXAMPLE_SYS "C:\\ISExempl.sys"
#define EXAMSYS_BAK "ISExempl.bak"

// Variables to pass as parameters to ConfigAdd.

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ConfigAdd(HWND);

function ExFn_ConfigAdd(hMSI)
    STRING szKey, szValue, szRefKey;
begin

    // Load the target config file into memory.
    if ConfigFileLoad (EXAMPLE_SYS) < 0 then
        MessageBox ("Unable to load " + EXAMPLE_SYS + ".", SEVERE);
        abort;
    endif;
```

```

// Set up parameters for the first call to ConfigAdd.
szKey    = "DEVICE";
szValue  = "C:\\Exapp\\Exapp2.sys";
szRefKey = "Exapp.sys";

// Add the line DEVICE=C:\\Exapp\\Exapp2.SYS before the first
// statement that references Exapp.sys.
if (ConfigAdd (szKey, szValue, szRefKey, BEFORE) < 0) then
    MessageBox ("First call to ConfigAdd failed.", WARNING);
    abort;
endif;

// Set up parameters for the second call to ConfigAdd.
szKey    = "DEVICEHIGH";
szValue  = "C:\\Otherapp\\Otherapp.exe";
szRefKey = "Otherapp.exe";

// Replace the last existing line that references OtherApp.exe
// with the statement DEVICEHIGH=C:\\Otherapp\\Otherapp.exe.
if (ConfigAdd (szKey, szValue, szRefKey, REPLACE) < 0) then
    MessageBox ("Second call to ConfigAdd failed.", WARNING);
    abort;
endif;

// Backup the original file and save the edited file.
if ConfigFileSave (EXAMSYS_BAK) < 0 then
    MessageBox ("Unable to save " + EXAMPLE_SYS + ".", SEVERE);
else
    MessageBox (EXAMPLE_SYS + " was updated and saved.", INFORMATION);
endif;

end;

```

## ConfigDelete

The **ConfigDelete** function removes lines from the system configuration file that has been loaded into memory by a call to **ConfigFileLoad**. The parameter **szKey** specifies a reference key that identifies the lines to be deleted. After using advanced configuration functions to edit a system configuration file, you must call **ConfigFileSave** to save your changes.

**Note** ▪ Do not mix the Ez batch file functions with the advanced batch file functions. After calling **BatchFileLoad**, you cannot use Ez batch file functions until you have called **BatchFileSave** to save the file.

### Syntax

```
ConfigDelete ( szKey );
```

## Parameters

**Table 48** ▪ ConfigDelete Parameters

| Parameter    | Description                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b> | Specifies the reference key that identifies the line or lines to delete. Common reference keys include Himem.sys, FILES, and STACKS. |

## Return Values

**Table 49** ▪ ConfigDelete Return Values

| Return Value  | Description                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | ConfigDelete successfully deleted the lines containing the reference key from the system configuration file. |
| <b>&lt; 0</b> | ConfigDelete was unable to delete the specified lines.                                                       |

## ConfigDelete Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ConfigDelete function.
*
* This example script deletes statements from a configuration
* file. First, it calls ConfigFileLoad to load the file for
* editing. Next, it deletes lines that contain a FILES
* statement. Finally, it backs up the original file and
* saves the edited file.
*
* Note: Before running this script, create a configuration
*       file named ISExempl.sys in the root of drive C.
*       That file should include at least one FILES statement.
*
\*-----*/

#define TARGET_CONFIG "C:\\ISExempl.sys"
#define BACKUP_CONFIG "ISExempl.bak"

// Include Ifx.h for built-in InstallScript function prototypes.
```

```

#include "Ifx.h"

export prototype ExFn_ConfigDelete(HWND);

function ExFn_ConfigDelete(hMSI)
    STRING szMsg;
begin

    // Load the target config file to be edited.
    if (ConfigFileLoad (TARGET_CONFIG) < 0) then
        MessageBox ("Unable to load " + TARGET_CONFIG + ".", SEVERE);
        abort;
    endif;

    // Remove all lines in the file that contain the key "FILES".
    if (ConfigDelete ("FILES") < 0) then
        MessageBox ("ConfigDelete failed.", SEVERE);
    else
        // Back up the original file and save the edited file.
        if ConfigFileSave (BACKUP_CONFIG) < 0 then
            MessageBox ("Unable to save " + TARGET_CONFIG + ".", SEVERE);
        else
            MessageBox (TARGET_CONFIG + " was updated and saved.", INFORMATION);
        endif;
    endif;

end;

```

## ConfigFileLoad

The **ConfigFileLoad** function loads a copy of the specified system configuration file into memory so that other advanced configuration file functions can be called to operate on the file. Specify the name of the system configuration file you want to edit in szConfigFile or pass a null string ("" ) in szConfigFile to edit the default system configuration file, which is set initially by the installation to the bootup Config.sys file that is used by the system.

**Note** ▪ Before using any of the advanced configuration file functions, you must first call **ConfigFileLoad** to load the system configuration file into memory. After you modify the file, call **ConfigFileSave** to save it to disk. To obtain the fully qualified name of the default system configuration file, call **ConfigGetFileName**. To make another file the default system configuration file, call **ConfigSetFileName**.

Note that you cannot call **ConfigFileLoad** to create a new configuration file. To create a new configuration file, use **CreateFile** and **CloseFile**; this creates an empty file. Then use **ConfigFileLoad** and other functions to load and modify the file as needed.

Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling the **ConfigFileLoad** function, you cannot use the Ez configuration file functions until you use the **ConfigFileSave** function to save your changes.

### Syntax

```
ConfigFileLoad ( szConfigFile );
```

## Parameters

**Table 50** ▪ ConfigFileLoad Parameters

| Parameter           | Description                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConfigFile</b> | Specifies the fully qualified name of the system configuration file to load into memory. To load the default system configuration file, pass a null string ("") in this parameter. |

## Return Values

**Table 51** ▪ ConfigFileLoad Return Values

| Return Value  | Description                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | ConfigFileLoad successfully initialized the configuration file buffer. If szConfigFile specified an existing configuration file, the file was loaded into the buffer; otherwise, an empty buffer was created. |
| <b>&lt; 0</b> | ConfigFileLoad was unable to initialize the configuration file buffer.                                                                                                                                        |

## ConfigFileLoad Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ConfigFileLoad and ConfigFileSave functions.
*
* This example script shows how to open a configuration file
* for editing, how to create a backup of the original file,
* and how to save and close the edited file.
*
* To demonstrate how the file backup feature of ConfigFileSave
* prevents the overwriting of existing files, this script loads
* and saves two different configuration files. The first file
* is backed up with a specific file name. The second is backed
* up with a wildcard extension so that ConfigFileSave will
* generate a unique file extension consisting of three digits.
*
* Note: Before running this script, create two files
*       (IExamp1.sys and IExamp2.sys) in the root of
*       drive C. For best effect, you should delete or
*       move any other files named IExamp1.* or IExamp2.*.
```

```

*
\*-----*/

// Names of Config files and backup files used in this example.
#define EXAMPLE1 "ISEXAMP1"
#define EXAMPLE2 "ISEXAMP2"

// Full names of Config files.
#define EXAMPLE1_SYS "C:\\\" + EXAMPLE1 + ".sys"
#define EXAMPLE2_SYS "C:\\\" + EXAMPLE2 + ".sys"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ConfigFileLoad(HWND);

function ExFn_ConfigFileLoad(hMSI)
begin

    // Load EXAMPLE1_SYS.
    if (ConfigFileLoad (EXAMPLE1_SYS) < 0) then
        MessageBox ("Unable to load " + EXAMPLE1_SYS + ".", SEVERE);
        abort;
    endif;

    // Use other Config functions here to edit the first file.

    // Back up the original file with the extension 'bak'; save the
    // edited file under its original name. If ISExamp1.bak already
    // exists, ConfigFileSave will generate a numbered extension.
    if (ConfigFileSave (EXAMPLE1 + ".bak") < 0) then
        MessageBox ("Unable to save " + EXAMPLE1_SYS + ".", SEVERE);
        abort;
    else
        MessageBox (EXAMPLE1_SYS + " saved.", INFORMATION);
    endif;

    // Load EXAMPLE2_SYS.
    if (ConfigFileLoad (EXAMPLE2_SYS) < 0) then
        MessageBox ("Unable to load " + EXAMPLE2_SYS + ".", SEVERE);
        abort;
    endif;

    // Use other Config file functions here to edit the second file.

    // Back up the original Config file with a numbered extension
    // and save the edited file under its original name.
    if (ConfigFileSave (EXAMPLE2 + ".*") < 0) then
        MessageBox ("Unable to save " + EXAMPLE2_SYS + ".", SEVERE);
        abort;
    else
        MessageBox (EXAMPLE2_SYS + " saved.", INFORMATION);
    endif;

end;

```

# ConfigFileSave

The **ConfigFileSave** function saves to disk a system configuration file that has been loaded into memory with the function **ConfigFileLoad**. The file is saved under its original name. If a file name is specified in `szBackupFile`, the original file is renamed with that file name before the edited file is written to disk. If `szBackupFile` contains a null string (""), the original file is replaced with the modified file. If you do not call **ConfigFileSave** when you are finished modifying a system configuration file with advanced configuration file functions, all modifications will be lost.

---

**Note** ▪ Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling the **ConfigFileLoad** function, you cannot use the Ez configuration file functions until you use the **ConfigFileSave** function to save your changes.

## Syntax

```
ConfigFileSave ( szBackupFile );
```

## Parameters

**Table 52** ▪ ConfigFileSave Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szBackupFile</b> | <p>Specifies whether or not a backup copy of the original file as it existed before editing should be saved, according to the following criteria:</p> <ul style="list-style-type: none"> <li>• If no backup file should be created, specify a null string in this parameter.</li> <li>• If the original file should be backed up with a specific name, pass that file name in this parameter. The file name must be unqualified (that is, do not specify a drive and/or path). Note that if a file with the specified name already exists, ConfigFileSave generates a unique file extension, as described in the next bullet item.</li> <li>• If the original file should be backed up with an installation-generated file extension, specify the wildcard character (*) as the file extension (for example, "Config.*"). The installation then assigns a numeric value, starting at 001, as the extension. If a file already exists with that extension, the extension's value is increased by one until a unique file name is created.</li> </ul> <p>Once the backup has been created, InstallShield stores the backup file name in the system variable <b>INFOFILENAME</b>.</p> |

## Return Values

**Table 53** ▪ ConfigFileSave Return Values

| Return Value  | Description                                                     |
|---------------|-----------------------------------------------------------------|
| <b>0</b>      | ConfigFileSave successfully wrote the file from memory to disk. |
| <b>&lt; 0</b> | ConfigFileSave was unable to write the file to disk.            |

## ConfigFileSave Example

end;

```

## ConfigFind

The **ConfigFind** function searches a system configuration file that has been loaded into memory with the function [ConfigFileLoad](#). The parameter szRefKey is a reference key that specifies the search target in that file. If the reference key is found, its value is returned in svResult. To find all occurrences of szRefKey, call this function repeatedly with nOptions set to CONTINUE. To restart the search from the top of the file, specify the constant RESTART in nOptions. After you edit the file, call [ConfigFileSave](#) to save it.

---

**Note** - Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling the ConfigFileLoad function, you cannot use the Ez configuration file functions until you use the ConfigFileSave function to save your changes.

### Syntax

```
ConfigFind (szRefKey, svResult, nOptions);
```

## Parameters

**Table 54** • ConfigFind Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szRefKey</b> | Specifies the reference key to search for. If the reference key is a file name without a file extension, all file extensions are included in the search. For example, if you specify Win.com, the search looks only for that reference key. If you specify WIN, the files Win.exe, Win.dll, Win.sys, etc., are all returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>svResult</b> | Returns the value of the reference key that was found in the system configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>nOptions</b> | <p>Indicates whether to start the search from the beginning of the file or to continue from where the previous search was terminated. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>RESTART</b>—Starts the search from the beginning of the file.</li> <li>● <b>CONTINUE</b>—Starts the search from the current position in the system configuration file.</li> <li>● <b>COMMAND</b>—Indicates that the reference key in szRefKey is a command, not an environment variable. The constant COMMAND can be joined with the constant RESTART or the constant CONTINUE by using the bitwise OR operator ( ), as in the following example:</li> </ul> <pre>ConfigFind("Vga.drv", svResult, CONTINUE   COMMAND);</pre> <div>  <p><b>Note</b> • A system configuration file can contain both environment variables and commands. To distinguish between environment variables and commands with the same name, use the constant COMMAND to specify that you are looking for executable commands.</p> </div> |

## Return Values

**Table 55** • ConfigFind Return Values

| Return Value | Description                                                                            |
|--------------|----------------------------------------------------------------------------------------|
| 0            | ConfigFind successfully found the specified reference key and returned it in svResult. |
| < 0          | ConfigFind was unable to find the specified reference key.                             |

## ConfigFind Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the ConfigFind function.
 *
 * This example script searches a batch file and reports whether
 * or not the file includes a BUFFERS command. It then finds
 * and displays all commands that reference Abc44.sys.
 *
 * Note: Before running this script, create a configuration
 *       file called ISExempl.sys and store it in the root
 *       of drive C. The configuration file should include
 *       the following lines:
 *
 *       DEVICE=C:\Abc44.sys /e:300
 *       DEVICE=C:\Abc44.sys /s:off
 *       BUFFERS=50
 *
 \*-----*/

#define EXAMPLE_SYS "C:\\ISExempl.sys"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ConfigFind(HWND);

function ExFn_ConfigFind(hMSI)
    STRING svResult;
    NUMBER nResult;
begin

    // Load EXAMPLE_SYS.
    if (ConfigFileLoad (EXAMPLE_SYS) < 0) then

```

```

        MessageBox ("Unable to load " + EXAMPLE_SYS + ".", SEVERE);
        abort;
    endif;

    // Check for a BUFFERS command. RESTART is passed in the
    // third parameter to begin searching at the top of the file.
    nResult = ConfigFind("BUFFERS", svResult, RESTART);

    if (nResult < 0) then
        MessageBox ("BUFFERS command not found.", WARNING);
    else
        MessageBox (svResult, INFORMATION);
    endif;

    // Find the first command that references Abc44.sys.
    nResult = ConfigFind ("Abc44.sys", svResult, COMMAND | RESTART);

    if nResult < 0 then
        MessageBox ("The file Abc44.sys is not referenced.", WARNING);
    else

        // Loop while matching statements are found.
        while nResult = 0
            // Display the matching statement.
            MessageBox (svResult, INFORMATION);

            // Find the next statement that references Abc44.sys.
            nResult = ConfigFind ("Abc44.sys", svResult, CONTINUE);
        endwhile;

        MessageBox ("No more matches on Abc44.sys.", WARNING);

    endif;

end;

```

## ConfigGetFileName

The **ConfigGetFileName** function retrieves the fully qualified name of the default system configuration file, which is set initially by InstallShield to the Config.sys file that was executed when the target system was started. To specify a different batch file to be used by default in the script, call **ConfigSetFileName**.

**Note** - Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling the **ConfigFileLoad** function, you cannot use the Ez configuration file functions until you use the **ConfigFileSave** function to save your changes.

### Syntax

```
ConfigGetFileName (svFileName);
```

## Parameters

**Table 56** ▪ ConfigGetFileName Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svFileName</b> | Returns the fully qualified name of the default system configuration file.                                                                                                                                                                                                                           |
|                   |  <p><b>Note</b> ▪ In rare circumstances, <i>InstallShield</i> might not be able to determine the fully qualified name of the default configuration file. In that case, <i>svFileName</i> is a null string ("").</p> |

## Return Values

**Table 57** ▪ ConfigGetFileName Return Values

| Return Value  | Description                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | ConfigGetFileName successfully retrieved the fully qualified name of the default system configuration file. |
| <b>&lt; 0</b> | ConfigGetFileName was unable to retrieve the fully qualified name of the default system configuration file. |

## ConfigGetFileName Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ConfigGetFileName and ConfigSetFileName
* functions.
*
* This example script retrieves the fully qualified name of the
* default configuration file, which initially is the Config.sys
* file on the boot drive. It then makes C:\ISExempl.sys the
* default configuration file. Finally, it retrieves the name of
* the default configuration file again to show that it has been
* changed.
*
```

```

\*-----*/

#define DEFAULT_CONFIG_FILE "C:\\ISExempl.sys"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_ConfigGetFileName(HWND);

function ExFn_ConfigGetFileName(hMSI)
    STRING svFilename;
begin

    // Get and display the name of the default configuration file.
    if (ConfigGetFileName (svFilename) < 0) then
        // Report the error; then terminate.
        MessageBox ("First call to ConfigGetFileName failed.", SEVERE);
        abort;
    else
        // Display the name of the default configuration file.
        MessageBox ("The default configuration file is " + svFilename + ".",
                    INFORMATION);
    endif;

    // Make C:\\ISExempl.sys the default configuration file.
    if (ConfigSetFileName (DEFAULT_CONFIG_FILE) < 0) then
        // Report the error.
        MessageBox ("Unable to set new default configuration file.", SEVERE);
    else

        // Verify that the default configuration file has been changed.
        if (ConfigGetFileName (svFilename) = 0) then
            // Display the name of the default configuration file.
            MessageBox ("Now the default configuration file is " + svFilename +
                        ".", INFORMATION);
        else
            // Report the error.
            MessageBox ("Second call to ConfigGetFileName failed.", SEVERE);
        endif;
    endif;

end;

```

## ConfigGetInt

The **ConfigGetInt** function retrieves the integer value of a reference key from a system configuration file that has been loaded into memory with the function [ConfigFileLoad](#). ConfigGetInt retrieves values from commands that have only one value to the right of the equal sign (=).

**Note** ▪ *ConfigGetInt* does not work on a command that has more than one value. For example, *ConfigGetInt* recognizes the statement *FILES=20* and returns the number 20, but it does not recognize the statement *STACKS=9,128*.

Before calling *ConfigGetInt*, you must first call *ConfigFileLoad* to load the system configuration file into memory. After you edit the file, call *ConfigFileSave* to save the file.

Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling the *ConfigFileLoad* function, you cannot use the Ez configuration file functions until you use the *ConfigFileSave* function to save your changes.

## Syntax

```
ConfigGetInt ( szKey, nvValue );
```

## Parameters

**Table 58** ▪ *ConfigGetInt* Parameters

| Parameter      | Description                                                                            |
|----------------|----------------------------------------------------------------------------------------|
| <b>szKey</b>   | Specifies the reference key of the statement from which to retrieve the integer value. |
| <b>nvValue</b> | Returns the integer value of the reference key.                                        |

## Return Values

**Table 59** ▪ *ConfigGetInt* Return Values

| Return Value  | Description                                                   |
|---------------|---------------------------------------------------------------|
| <b>0</b>      | <i>ConfigGetInt</i> successfully retrieved the integer value. |
| <b>&lt; 0</b> | <i>ConfigGetInt</i> was unable to retrieve the integer value. |

## ConfigGetInt Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
```

```

* Demonstrates the ConfigGetInt and ConfigSetInt functions.
*
* This example script gets the current value of the FILES
* command from a configuration file. If a FILES command is not
* found, the command FILES=40 is added to the file. If a FILES
* command is found, its value is tested. If the value is less
* than 40, the command is replaced with the command FILES=40.
*
* Note: Before running this script, create a configuration file
*       called ISExempl.sys in the root directory of drive C.
*       That file should include the following line:
*
*       FILES=20;
*
\*-----*/

#define EXAMPLE_SYS "C:\\ISExempl.sys"
#define EXAMPLE_BAK "ISExempl.bak"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ConfigGetInt(HWND);

function ExFn_ConfigGetInt(hMSI)
    NUMBER nvValue;
    BOOL    bFileChanged;
begin
    // Load the configuration file.
    if (ConfigFileLoad (EXAMPLE_SYS) < 0) then
        MessageBox ("Unable to load " + EXAMPLE_SYS + ".", SEVERE);
        abort;
    endif;

    // Initialize indicator to show if file was updated.
    bFileChanged = FALSE;

    // Find the command "FILES" in the configuration file.
    if (ConfigGetInt ("FILES", nvValue) < 0) then

        // No FILES command found. Add FILES command.
        if ConfigAdd ("FILES", "40", "", AFTER) = 0 then
            MessageBox ("FILES=40 added to " + EXAMPLE_SYS + ".", INFORMATION);
            bFileChanged = TRUE;
        else
            MessageBox ("FILES command not found. Unable to update " +
                EXAMPLE_SYS + ".", SEVERE);
        endif;
    else

        // FILES command found.
        if (nvValue >= 40) then
            // FILES command setting is ok.

```

```

        SprintfBox (INFORMATION, "ConfigGetInt Example",
                    "FILES=%d; no change required.", nvValue);
    else

        // FILES command needs to be changed.
        if (ConfigSetInt ("FILES", 40) < 0) then
            MessageBox ("Unable to update "+EXAMPLE_SYS + ".", SEVERE);
        else
            MessageBox ("The FILES setting was changed to 40.", INFORMATION);
            bFileChanged = TRUE;
        endif;

    endif;

endif;

// If the file was edited, save it.
if bFileChanged then

    // Back up the original file with the extension 'bak'; save the
    // edited file under its original name.  If ISExamp1.bak already
    // exists, ConfigFileSave will generate a numbered extension.
    if (ConfigFileSave (EXAMPLE_BAK) < 0) then
        MessageBox ("Unable to save " + EXAMPLE_SYS + ".", SEVERE);
    else
        MessageBox (EXAMPLE_SYS + " saved.", INFORMATION);
    endif;

endif;

end;

```

## ConfigMove

The **ConfigMove** function moves a line in a system configuration file that has been loaded into memory with the function **ConfigFileLoad**. The line can be moved to the first or last position in the file or before or after a specific line in the file.

**Note** ▪ Before calling the **ConfigMove** function, you must first call **ConfigFileLoad** to load the **Config.sys** file into memory. After you edit the file, call **ConfigFileSave** to save the file.

Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling the **ConfigFileLoad** function, you cannot use the Ez configuration file functions until you use the **ConfigFileSave** function to save your changes.

### Syntax

```
ConfigMove ( szMove, szRefKey, nOptions );
```

## Parameters

**Table 60** ▪ ConfigMove Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMove</b>   | Specifies the line to move.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>szRefKey</b> | Specifies the key that identifies the reference line used to position the line to be moved. The position of the line to be moved is determined by the value of nOptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>nOptions</b> | <p>Specifies whether you are moving the line in szMove before or after the line that contains the reference key in szRefKey. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>BEFORE</b>—The line specified by szMove is placed before the line containing szRefKey. If szMove is a null string (""), the line is placed before the first line in the system configuration file.</li> <li>• <b>AFTER</b>—The line specified by szMove is placed after the line containing szRefKey. If szMove is a null string (""), the line is placed after the last line in the system configuration file.</li> </ul> |

## Return Values

**Table 61** ▪ ConfigMove Return Values

| Return Value  | Description                                                                        |
|---------------|------------------------------------------------------------------------------------|
| <b>0</b>      | ConfigMove successfully moved the specified line in the system configuration file. |
| <b>&lt; 0</b> | ConfigMove was unable to move the line.                                            |

## ConfigMove Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
```

```

* InstallShield Example Script
*
* Demonstrates the ConfigMove function.
*
* This example script moves lines in a configuration file.
* First, it calls ConfigFileLoad to load the file. Next, it
* moves the FILES statement to the end of the file. Then,
* it moves the BUFFERS statement to the end of the file.
* Next, it moves the statement referencing Himem.sys before
* the DOS statement. Finally, it backs up the original file
* and saves the edited file.
*
* Note: Before running this script, create a configuration
*       file called ISExempl.sys in the root of drive C.
*       That file should include the following lines:
*
*       FILES=50
*       DOS=HIGH,UMB
*       DEVICE=C:\WINDOWS\SETVER.EXE
*       BUFFERS=50
*       Device=C:\Windows\Himem.sys
*
\*-----*/

#define TARGET_CONFIG "C:\\ISExempl.sys"
#define BACKUP_CONFIG "ISExempl.bak"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ConfigMove(HWND);

function ExFn_ConfigMove(hMSI)
begin

    // Load the configuration file to be edited.
    if ConfigFileLoad (TARGET_CONFIG) < 0 then
        MessageBox ("Unable to load " + TARGET_CONFIG + ".", SEVERE);
        abort;
    endif;

    // Move the FILES statement to the end of the file.
    if (ConfigMove ("FILES", "", AFTER) < 0) then
        MessageBox ("Unable to move FILES statement.", SEVERE);
    else
        MessageBox ("FILES statement moved to the end of the file.",
                    INFORMATION);
    endif;

    // Move the BUFFERS statement to the end of the file.
    if (ConfigMove ("BUFFERS", "", AFTER) < 0) then
        MessageBox ("Unable to move BUFFERS statement.", SEVERE);
    else
        MessageBox ("BUFFERS statement moved to the end of the file.",
                    INFORMATION);
    endif;
end;

```

```

// Move the Himem.sys statement before the DOS statement.
if (ConfigMove ("Himem.sys", "DOS", BEFORE) < 0) then
    MessageBox ("Unable to move Himem.sys statement.", SEVERE);
else
    MessageBox ("Himem.sys statement moved before DOS statement.",
        INFORMATION);
endif;

// Save the updated file; back up the original file.
if ConfigFileSave (BACKUP_CONFIG) < 0 then
    MessageBox ("Unable to save " + BACKUP_CONFIG+".", SEVERE);
else
    MessageBox ("Config file saved. Backup created.", INFORMATION);
endif;

end;

```

## ConfigSetFileName

The **ConfigSetFileName** function specifies the fully qualified name of the file you want to use as the default system configuration file. During installation initialization, the installation identifies the Config.sys file that was executed when the target system was started and makes it the default system configuration file. If this is the only system configuration file your installation will edit, it is unnecessary to call this function. Ez configuration files will use that file and the advanced configuration function **ConfigFileLoad** will open that file when its parameter is a null string ("").

However, if you want to use Ez configuration file functions to modify a configuration file other than the bootup Config.sys file, you must call ConfigSetFileName to change the default system configuration file. For example, suppose you wanted to create a Config.sys file on the target system that would not be used at bootup time. You can set a file name in the application directory. Ez configuration file functions would operate on that file. If you call ConfigFileLoad with a null parameter, that file is loaded into memory, where it can be edited with advanced file functions.

---

**Caution** ▪ The **ConfigSetFileName** function does not load a system configuration file into memory. You must use **ConfigFileLoad** to load a file into memory.

*ConfigSetFileName does not validate the file name you specify. If you specify an invalid file name, all future configuration file functions fail.*

---

**Note** ▪ Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling the **ConfigFileLoad** function, you cannot use the Ez configuration file functions until you use the **ConfigFileSave** function to save your changes.

### Syntax

```
ConfigSetFileName ( szConfigFile );
```

## Parameters

**Table 62** ▪ ConfigSetFileName Parameters

| Parameter           | Description                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------|
| <b>szConfigFile</b> | Specifies the fully qualified name of the file to set as the default system configuration file. |

## Return Values

**Table 63** ▪ ConfigSetFileName Return Values

| Return Value  | Description                                                                       |
|---------------|-----------------------------------------------------------------------------------|
| <b>0</b>      | ConfigSetFileName successfully retrieved the specified system configuration file. |
| <b>&lt; 0</b> | ConfigSetFileName was unable to retrieve the specified file.                      |

## ConfigSetFileName Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ConfigGetFileName and ConfigSetFileName
* functions.
*
* This example script retrieves the fully qualified name of the
* default configuration file, which initially is the Config.sys
* file on the boot drive. It then makes C:\ISExempl.sys the
* default configuration file. Finally, it retrieves the name of
* the default configuration file again to show that it has been
* changed.
*
\*-----*/

#define DEFAULT_CONFIG_FILE "C:\\ISExempl.sys"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ConfigSetFileName(HWND);

function ExFn_ConfigSetFileName(hMSI)
```

```

    STRING svFilename;
begin

    // Get and display the name of the default configuration file.
    if (ConfigGetFileName (svFilename) < 0) then
        // Report the error; then terminate.
        MessageBox ("First call to ConfigGetFileName failed.", SEVERE);
        abort;
    else
        // Display the name of the default configuration file.
        MessageBox ("The default configuration file is " + svFilename + ".",
                    INFORMATION);
    endif;

    // Make C:\ISExampl.sys the default configuration file.
    if (ConfigSetFileName (DEFAULT_CONFIG_FILE) < 0) then
        // Report the error.
        MessageBox ("Unable to set new default configuration file.", SEVERE);
    else

        // Verify that the default configuration file has been changed.
        if (ConfigGetFileName (svFilename) = 0) then
            // Display the name of the default configuration file.
            MessageBox ("Now the default configuration file is " + svFilename +
                        ".", INFORMATION);
        else
            // Report the error.
            MessageBox ("Second call to ConfigGetFileName failed.", SEVERE);
        endif;
    endif;

end;

```

## ConfigSetInt

The **ConfigSetInt** function changes a specified integer value in a system configuration file that has been loaded into memory with the function **ConfigFileLoad**. ConfigSetInt sets values in commands that have only one value to the right of the equal sign (=).

**Note** - This function does not work on a command that has more than one value. For example, ConfigSetInt recognizes the statement FILES=20 and can change 20 to another value, but it does not recognize the statement STACKS=9,128.

Before calling ConfigSetInt, you must first call ConfigFileLoad to load the system configuration file into memory. After you edit the file, call **ConfigFileSave** to save the file.

Do not mix the Ez configuration file functions with the advanced configuration file functions. After calling the ConfigFileLoad function, you cannot use the Ez configuration file functions until you use the ConfigFileSave function to save your changes.

## Syntax

```
ConfigSetInt ( szKey, nValue );
```

## Parameters

**Table 64** ▪ ConfigSetInt Parameters

| Parameter     | Description                                                                      |
|---------------|----------------------------------------------------------------------------------|
| <b>szKey</b>  | Specifies the reference keyword of the command whose integer value is to be set. |
| <b>nValue</b> | Specifies the integer value you want to set for the command in szKey.            |

## Return Values

**Table 65** ▪ ConfigSetInt Return Values

| Return Value  | Description                                                                           |
|---------------|---------------------------------------------------------------------------------------|
| <b>0</b>      | ConfigSetInt successfully set the specified integer in the system configuration file. |
| <b>&lt; 0</b> | ConfigSetInt was unable to set the specified integer.                                 |

## ConfigSetInt Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ConfigGetInt and ConfigSetInt functions.
*
* This example script gets the current value of the FILES
* command from a configuration file. If a FILES command is not
* found, the command FILES=40 is added to the file. If a FILES
* command is found, its value is tested. If the value is less
* than 40, the command is replaced with the command FILES=40.
*
* Note: Before running this script, create a configuration file
*       called ISExmpl.sys in the root directory of drive C.
*       That file should include the following line:
*
*       FILES=20;
```

```

*
\*-----*/

#define EXAMPLE_SYS "C:\\ISExempl.sys"
#define EXAMPLE_BAK "ISExempl.bak"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ConfigSetInt(HWND);

function ExFn_ConfigSetInt(hMSI)
    NUMBER nvValue;
    BOOL    bFileChanged;
begin

    // Load the configuration file.
    if (ConfigFileLoad (EXAMPLE_SYS) < 0) then
        MessageBox ("Unable to load " + EXAMPLE_SYS + ".", SEVERE);
        abort;
    endif;

    // Initialize indicator to show if file was updated.
    bFileChanged = FALSE;

    // Find the command "FILES" in the configuration file.
    if (ConfigGetInt ("FILES", nvValue) < 0) then

        // No FILES command found. Add FILES command.
        if ConfigAdd ("FILES", "40", "", AFTER) = 0 then
            MessageBox ("FILES=40 added to " + EXAMPLE_SYS + ".", INFORMATION);
            bFileChanged = TRUE;
        else
            MessageBox ("FILES command not found. Unable to update " +
                EXAMPLE_SYS + ".", SEVERE);
        endif;
    else

        // FILES command found.
        if (nvValue >= 40) then
            // FILES command setting is ok.
            sprintfBox (INFORMATION, "ConfigGetInt Example",
                "FILES=%d; no change required.", nvValue);
        else

            // FILES command needs to be changed.
            if (ConfigSetInt ("FILES", 40) < 0) then
                MessageBox ("Unable to update "+EXAMPLE_SYS + ".", SEVERE);
            else
                MessageBox ("The FILES setting was changed to 40.", INFORMATION);
                bFileChanged = TRUE;
            endif;
        endif;
    endif;
end;

```

```

endif;

// If the file was edited, save it.
if bFileChanged then

    // Back up the original file with the extension 'bak'; save the
    // edited file under its original name. If ISExamp1.bak already
    // exists, ConfigFileSave will generate a numbered extension.
    if (ConfigFileSave (EXAMPLE_BAK) < 0) then
        MessageBox ("Unable to save " + EXAMPLE_SYS + ".", SEVERE);
    else
        MessageBox (EXAMPLE_SYS + " saved.", INFORMATION);
    endif;

endif;

end;

```

## ConvertSizeToUnits

The **ConvertSizeToUnits** function converts the size specified through nSizeSrcHigh and nSizeSrcLow in nUnitsSrc into nvSizeTargetHigh and nvSizeTargetLow in nUnitsTarget. You can also use this function to determine the best units to use for a particular size value that is not known until the setup is run.

### Syntax

```

ConvertSizeToUnits ( nSizeSrcHigh, nSizeSrcLow, nUnitsSrc, nvSizeTargetHigh, nvSizeTargetLow,
                    nvUnitsTarget );

```

## Parameters

**Table 66** ▪ CovertSizeToUnits Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nSizeSrcHigh</b>     | Specifies the upper 31 bits of the size to be converted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>nSizeSrcLow</b>      | Specifies the lower 31 bits of the size to be converted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>nUnitsSrc</b>        | <p>The units of nSizeSrcHigh and nSizeSrcLow. Specify one of the following values:</p> <ul style="list-style-type: none"> <li>● <b>BYTES</b>—The value is in bytes.</li> <li>● <b>KBYTES</b>—The value is in kilobytes.</li> <li>● <b>MBYTES</b>—The value is in megabytes.</li> <li>● <b>GBYTES</b>—The value is in gigabytes.</li> <li>● <b>TBYTES</b>—The value is in terabytes.</li> </ul>                                                                                                                                                                                                                 |
| <b>nvSizeTargetHigh</b> | Returns the upper 31 bits of converted size.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>nvSizeTargetLow</b>  | Returns the lower 31 bits of converted size.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>nUnitsTarget</b>     | <p>Specifies (and returns if -1 is specified) the units of nvSizeTargetHigh and nvSizeTargetLow. Specify one of the following values. (You can also specify -1 or any negative value. In this case, the function sets nUnitsTarget to the smallest units that ensures that nvSizeTargetHigh is 0):</p> <ul style="list-style-type: none"> <li>● <b>BYTES</b>—The value is in bytes.</li> <li>● <b>KBYTES</b>—The value is in kilobytes.</li> <li>● <b>MBYTES</b>—The value is in megabytes.</li> <li>● <b>GBYTES</b>—The value is in gigabytes.</li> <li>● <b>TBYTES</b>—The value is in terabytes.</li> </ul> |

## Return Values

**Table 67** ▪ ConvertSizeToUnits Return Values

| Return Value         | Description                                 |
|----------------------|---------------------------------------------|
| <b>ISERR_SUCCESS</b> | Indicates that the function was successful. |

**Table 67** ▪ ConvertSizeToUnits Return Values (cont.)

| Return Value             | Description                                                    |
|--------------------------|----------------------------------------------------------------|
| < <b>ISERR_SUCCESS</b>   | Indicates that the function was not successful.                |
| <b>ISERR_INVALID_ARG</b> | Indicates that either nSizeSrcHigh or nSizeSrcLow is negative. |

## ConvertWinHighLowSizeToISHighLowSize

The **ConvertWinHighLowSizeToISHighLowSize** function converts the unsigned 64-bit Windows size specified through nSizeWinHigh and nSizeWinLow to the corresponding 62-bit InstallShield high and low size value.

### Syntax

```
ConvertWinHighLowSizeToISHighLowSize ( nSizeWinHigh, nSizeWinLow, nvSizeISHigh, nvSizeISLow);
```

## Parameters

**Table 68** ▪ ConvertWinHighLowSizeToISHighLowSize Parameters

| Parameter           | Description                                                       |
|---------------------|-------------------------------------------------------------------|
| <b>nSizeWinHigh</b> | Specifies the upper 31 bits of the Windows 64-bit size value.     |
| <b>nSizeWinLow</b>  | Specifies the lower 31 bits of the Windows 64-bit size value.     |
| <b>nSizeISHigh</b>  | Returns the upper 31 bits of the InstallShield 62-bit size value. |
| <b>nSizeISLow</b>   | Returns the lower 31 bits of the InstallShield 62-bit size value. |

## Return Values

**Table 69** ▪ ConvertWinHighLowSizeToISHighLowSize Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# CopyBytes

The **CopyBytes** function copies a specified number of bytes from one string to another string. You can specify the offset indices into the source and destination strings. CopyBytes is useful for working with binary files.

## Syntax

```
CopyBytes ( svDest, nIndexDest, svSrc, nIndexSrc, nCount );
```

## Parameters

**Table 70** ▪ CopyBytes Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svDest</b>     | Specifies the destination string.                                                                                                                                                                                                                                                          |
| <b>nIndexDest</b> | Specifies the offset index (starting point) in the destination string at which location the bytes are to be inserted. The first byte in the string is at position 0.                                                                                                                       |
| <b>svSrc</b>      | Specifies the source string. Do not pass an autosized string whose size is greater than 256 characters. Instead, declare the string with an explicit size. For more information about string sizing, see <a href="#">String Size and Autosize</a> .                                        |
| <b>nIndexSrc</b>  | Specifies the offset index (starting point) in the source string at which location bytes begin to be copied. The first byte in the string is at position 0.                                                                                                                                |
| <b>nCount</b>     | Specifies the total number of bytes you want to copy from svSrc to svDest. This value must be no larger than the size of svSrc - 1. For example, if svSrc was declared with a size of 512 (giving it a maximum string length of 511), then the value passed in nCount must be 511 or less. |

## Return Values

**Table 71** ▪ CopyBytes Return Values

| Return Value  | Description                                                                           |
|---------------|---------------------------------------------------------------------------------------|
| <b>0</b>      | CopyBytes successfully copied a specified number of bytes from one string to another. |
| <b>&lt; 0</b> | CopyBytes was unable to copy the bytes.                                               |

## CopyBytes Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function,

*execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.*

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CopyBytes function.
*
* This example script retrieves the current date from the
* target system. Then, it copies the year from the date and
* displays the year to the end user.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_CopyBytes(HWND);

function ExFn_CopyBytes(hMSI)
    STRING svDate, svYear;
    NUMBER nvResult, nIndexDate, nIndexYear, nCount;
begin

    // Get the date from the target system.
    GetSystemInfo (DATE, nvResult, svDate);

    // Set up parameters to pass to CopyBytes. The year is
    // in the last four bytes of svDate.
    nIndexYear = 0;
    nCount     = 4;
    nIndexDate  = StrLength(svDate) - nCount;

    // Copy the four bytes representing the year into svYear.
    if (CopyBytes (svYear, nIndexYear, svDate, nIndexDate, nCount) < 0) then
        // Report an error.
        MessageBox ("CopyBytes failed.", SEVERE);
    else
        // Display the year.
        MessageBox ("The year is " + svYear, INFORMATION);
    endif;

end;
```

## CopyCHARArrayToISStringArray

### Description

The **CopyCHARArrayToISStringArray** function copies the strings from an existing array of ANSI character strings (pointed to by pCharArray) to the existing string array specified by vArray.

### Syntax

```
CopyCHARArrayToISStringArray ( vArray, pCharArray );
```

## Parameters

**Table 72** ▪ CopyCharArrayToISStringArray Parameters

| Parameter         | Description                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vArray</b>     | Specifies the string array to which you want to copy strings.                                                                                                                    |
| <b>pCharArray</b> | Specifies a pointer to an array of pointers to ANSI character strings. Typically, this pointer is returned by a previous call to <a href="#">GetCharArrayFromISStringArray</a> . |

## Return Values

**Table 73** ▪ CopyCharArrayToISStringArray Return Values

| Return Value         | Description                                 |
|----------------------|---------------------------------------------|
| <b>ISERR_SUCCESS</b> | This function always returns ISERR_SUCCESS. |

## Additional Information

If **pCharArray** was returned by a previous call to [GetCharArrayFromISStringArray](#), be careful when modifying strings contained in the array. Since the length of the strings contained in string arrays are managed internally by the setup, if you change the length of a string the entire string will not be copied back to the original array when you call [CopyCharArrayToISStringArray](#).

# CopyFile

The **CopyFile** function creates a copy of the file specified by **szSrcFile**. The new file is given the name specified by **szTargetFile**. You must specify the name of the file that you want to copy onto the target location in the **szTargetFile** parameter of this function in order for the function to work.

If you use this function to transfer files to [WINSYSDIR64](#), you must first disable file system redirection using [WOW64FSREDIRECTION](#). Otherwise, files being transferred to WINSYSDIR64 are incorrectly redirected to the 32-bit SysWOW64 folder. Since some Windows functionality that could be used by the installation requires that redirection be enabled to work, Windows documentation recommends that you disable redirection only for as long as necessary. It is recommended that you then enable file system redirection as soon as you have completed transferring the necessary files to WINSYSDIR64. To learn more, see [Targeting 64-Bit Operating Systems with InstallScript Installations](#).

**Tip** ▪ It is strongly recommended that you disable the Cancel button using the **Disable** function before calling the **CopyFile** function if the status dialog is displayed during the copy. If you do not disable the Cancel button and the end user cancels during the copy file operation, the **OnCancelling** event handler is not called. Instead, the copy file operation returns a failure error code, which your script must handle by calling the appropriate event and then

relaunching the copy file operation. You can enable and disable the Cancel button using the [Enable](#) and [Disable](#) functions.

---

**Note** ▪ For file transfer, [XCopyFile](#) is an alternative to **CopyFile**. **XCopyFile** can perform version checking, mark locked .dll and .exe files for update after system restart, and increment registry reference counters for shared .dll and .exe files. You can also use **XCopyFile** to include subdirectories.

If you use unqualified file names and set values for SRCDIR and TARGETDIR when using **CopyFile**, save the current values using [VarSave](#) before calling **CopyFile** and then restore them using [VarRestore](#).

If the target directory does not exist, **CopyFile** creates it.

You cannot rename groups of files by using wildcards with **CopyFile**. You can, however, rename a single file using **CopyFile**.

## Syntax

```
CopyFile ( szSrcFile, szTargetFile );
```

## Parameters

**Table 74** ▪ CopyFile Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSrcFile</b>    | <p>Specify the name of the file to copy. If the file name is qualified—that is, if it includes a path—<b>CopyFile</b> copies the file from the specified location. If szSrcFile contains an unqualified file name—without path information—<b>CopyFile</b> copies from the directory that is identified by the system variable <b>SRCDIR</b>. To copy groups of files, use wild card characters in this parameter.</p> <p>You can specify a valid URL in this parameter. If you pass a CGI or ASP request (for example, "http://www.mydomain.net/login.asp?name=Me&amp;pwd=wow"), the response is sent to the file that is specified in the szTargetFile parameter. When passing a URL, do not include wildcard characters. To check the validity of a URL, call the following:</p> <pre>Is (VALID_PATH, szURL);</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>szTargetFile</b> | <p>Specify the name to give to the copy of the file that is identified by szSrcFile. If the file name is qualified—if it includes a path—<b>CopyFile</b> copies the file to the location specified by the path. If szSrcFile contains an unqualified file name—without path information—the copy is created in the directory specified by the system variable TARGETDIR (in InstallScript installations) or INSTALLDIR (in Basic MSI and InstallScript MSI installations). If the target directory does not exist, it is created.</p> <p>You cannot specify a URL in this parameter. If you do, the function fails and returns ISERR_INVALID_ARG.</p> <div>  <p><b>Note</b> ▪ When a wildcard character is included in the file name that is specified by szSrcFile, the file name part of szTargetFile is not ignored; instead, the szTargetFile value is treated as the target path to which each source file is copied to with its existing name. For example, the following code copies files to a folder named File.txt on the D drive:</p> <pre>CopyFile ("C:\\*.\"", "D:\\File.txt");</pre> <p>If szTargetFile specifies an unqualified file name, the files are copied to the directory that is specified by TARGETDIR (in InstallScript installations) or INSTALLDIR (in Basic MSI and InstallScript MSI installations). For that reason, <b>CopyFile</b> cannot be used to copy and rename a group of files. The source and target directories must be different when szSrcFile contains one or more wildcard characters.</p> </div> |

## Return Values

**Table 75** ▪ CopyFile Return Values

| Return Value              | Description                                                                                                                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                         | Indicates that the function successfully copied the files from source to target directory.                                                                                                                                                     |
| ISERR_INVALID_ARG         | Indicates that an invalid argument was passed to the function.                                                                                                                                                                                 |
| All other negative values | Indicates that the function was unable to copy the requested file.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

After you modify .ini files with [WriteProfString](#) or [WriteProfInt](#), you must flush the cache buffer under before using **CopyFile**. All .ini files are cached. This behavior can cause a delay in writing changes to the specified files. This delay can interfere with subsequent file operations. To avoid this problem, call **WriteProfString** with null parameters to force Windows to write the data to the .ini file immediately, as shown below:

```
WriteProfString ("C:\\Test.ini", "Windows",
"KeyboardDelay", "100");

// null string ("" ) for all four parameters
WriteProfString ("", "", "", "");

// CopyFile should now have access to updated file.
CopyFile ("C:\\Test.ini", "C:\\Temp\\Test.ini");
```

## CopyFile Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CopyFile function.
*
* This script copies files in the directory specified by
* SOURCE_DIR to the directory specified by TARGET_DIR.
*
* Note: Before running this script, you must set the
*       preprocessor constants to existing paths on
*       the target system.
*
\*-----*/
```

```

#define SOURCE_DIR "C:\\Source"
#define TARGET_DIR "C:\\Target"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_CopyFile(HWND);

function ExFn_CopyFile(hMSI)
    NUMBER nResult;
begin

    // Copy all files in the source directory, including files
    // in subdirectories, to the target directory.
    nResult = CopyFile(SOURCE_DIR ^ ".*", TARGET_DIR ^ ".*");

    // Report the results of the copy operation.
    switch (nResult)
    case 0:
        MessageBox ("Files successfully copied.", INFORMATION);
    case COPY_ERR_CREATEDIR:
        MessageBox ("A target directory could not be created.", SEVERE);
    case COPY_ERR_MEMORY:
        MessageBox ("Insufficient memory.", SEVERE);
    case COPY_ERR_NODISKSPACE:
        MessageBox ("Insufficint disk space.", SEVERE);
    case COPY_ERR_OPENINPUT:
        MessageBox ("Unable to open the input files in "+ SOURCE_DIR +".",
            SEVERE);
    case COPY_ERR_OPENOUTPUT:
        MessageBox ("Unable to copy the source files.", SEVERE);
    case COPY_ERR_TARGETREADONLY:
        MessageBox ("A target file already exists and cannot be overwritten.",
            SEVERE);
    default:
        MessageBox ("An unspecified error occurred.", SEVERE);
    endswitch;

end;

```

## CreateDir

The **CreateDir** function creates one or more subdirectories on the target drive. You can use a path that contains subdirectories on more than one level, such as C:\Programs\Winapps\Myapp. If any subdirectory in the path does not exist, CreateDir creates it. For example, if neither C:\Programs\Winapps nor C:\Programs\Winapps\Myapp exists, CreateDir creates both subdirectories.

**Caution** ▪ *CreateDir fails under the following conditions:*

- *The path is illegal.*
- *The drive or any subdirectory in the path is write-protected.*
- *The drive name is invalid.*

- You do not have network privileges to create subdirectories.

## Syntax

```
CreateDir ( szDirPath );
```

## Parameters

**Table 76** ▪ CreateDir Parameters

| Parameter        | Description                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDirPath</b> | Specifies the fully qualified path of the subdirectory to create. Separate each level in the path with a backslash by using the backslash escape character (\\). |

## Return Values

**Table 77** ▪ CreateDir Return Values

| Return Value  | Description                                                                                                                                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates either that the function successfully created the specified directory on the target drive or that the specified directory already exists.                                                                                                                     |
| <b>&lt; 0</b> | Indicates that the directory does not already exist and that the function was unable to create it. You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## CreateDir Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CreateDir function.
*
* The user is asked to input a valid directory. If the
* specified directory does not exist, CreateDir is called to
* create it. Then CreateDir is called again to create a
```

```

* multilevel directory structure beneath the specified
* directory.
*
\*-----*/

#define DEFAULT_DIR "C:\\ISExampl"
#define SUBDIRS     "N_Dir\\A_Dir"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_CreateDir(HWND);

function ExFn_CreateDir(hMSI)
    STRING svPath;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Prompt user for a directory to be created.
    AskPath ("Please enter a valid path.", DEFAULT_DIR, svPath);

    // Check to see if that directory already exists.
    if (ExistsDir (svPath) != EXISTS) then

        // The directory does not exist; create it.
        if (CreateDir (svPath) < 0) then
            // Report the error; then abort.
            MessageBox ("Unable to create directory", SEVERE);
            abort;
        else
            // Report success
            sprintfBox (INFORMATION, "CreateDir", "%s created.", svPath);
        endif;

    endif;

    // Create an entire multilevel directory structure
    // beneath the selected directory.
    if (CreateDir (svPath ^ SUBDIRS) < 0) then
        MessageBox ("Failed to create subdirectories beneath" + svPath + ".",
                    WARNING);
    else
        sprintfBox (INFORMATION, "CreateDir", "%s created beneath %s.", SUBDIRS,
                    svPath);
    endif;

end;

```

## CreateFile

The **CreateFile** function creates a new file. If a file with the same name exists, CreateFile overwrites it. Before you create a file with CreateFile, you must set the file mode with [OpenFileMode](#).

CreateFile leaves the newly created file open in read/write (binary file) or append (text file) mode so you can read from or write to the file using other functions such as GetLine, ReadBytes, WriteLine, and WriteBytes. To write to an existing file, you must first open the file in FILE\_MODE\_APPEND mode using the OpenFileMode and [OpenFile](#) functions.

---

**Note** ▪ In addition to read/write or append mode, all newly created files automatically open in OF\_SHARE\_DENY\_NONE mode. This means that the files are opened without denying other programs read or write access to the files. This mode has its roots in the Windows API OpenFile.

When you finish reading from and writing to a file, you must close the file using the [CloseFile](#) function.

## Syntax

```
CreateFile ( nvFileHandle, szPath, szFileName );
```

## Parameters

**Table 78** ▪ CreateFile Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvFileHandle</b> | Returns the handle of the new file.                                                                                                                                                                                                                                                                                                                                                   |
| <b>szPath</b>       | Specifies the fully qualified path of the subdirectory in which to create the new file.<br><br><br><b>Note</b> ▪ <i>CreateFile fails if the folder specified in szPath does not exist. You can test for the existence of a folder by calling ExistsDir and create a folder by calling CreateDir.</i> |
| <b>szFileName</b>   | Specifies the name of the file to create.                                                                                                                                                                                                                                                                                                                                             |

## Return Values

**Table 79** ▪ Return Values

| Return Value  | Description                                                          |
|---------------|----------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully created the new file.       |
| <b>&lt; 0</b> | Indicates that the function was unable to create the specified file. |

## Additional Information

The actions of the CreateFile function are not logged for uninstallation when logging is enabled. If you want a file that is created by CreateFile to be logged for uninstallation, transfer a starter file with the file name you want to the target system using [XCopyFile](#) while logging is enabled. You enable and disable logging with the [Enable](#) and [Disable](#) functions. XCopyFile actions are logged when logging is enabled, so the starter file is logged for uninstallation. After transferring the logged starter file, you can write to or overwrite the logged starter file using CreateFile and other file-related functions. The file name must remain unchanged; otherwise, it is not found during uninstallation.

## CreateFile Example

**Note** ▪ *To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.*

```
/*-----*\
*
```

```

* InstallShield Example Script
*
* Demonstrates the CreateFile and WriteLine functions.
*
* CreateFile is called to create a file to store a string. The
* string is written into the file by the WriteLine function.
*
* Note: Before running this script, set the preprocessor
*       constant EXAMPLE_DIR so that it references an existing
*       directory on the target system. Note that if the file
*       specified by EXAMPLE_FILE already exists, it will be
*       overwritten.
*
\*-----*/

#define EXAMPLE_DIR "C:\\\"
#define EXAMPLE_FILE "ISExmpl.txt"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_CreateFile(HWND);

function ExFn_CreateFile(hMSI)
    STRING  szTitle, szMsg;
    NUMBER  nvFileHandle;
begin

    // Set the file mode to append.
    OpenFileMode (FILE_MODE_APPEND);

    // Create a new file and leave it open.
    if (CreateFile (nvFileHandle, EXAMPLE_DIR, EXAMPLE_FILE) < 0) then
        // Report the error.
        MessageBox ("CreateFile failed.", SEVERE);
        abort;
    else
        // Set the message to write to the file.
        szMsg = "This line was appended by an example InstallShield script.";

        // Append the message to the file.
        if (WriteLine(nvFileHandle, szMsg) < 0) then
            // Report the error.
            MessageBox ("WriteLine failed.", SEVERE);
        else
            // Report success.
            szTitle = "CreateFile & WriteLine";
            szMsg    = "Successfully created and wrote to %s.";
            sprintfBox (INFORMATION, szTitle, szMsg, EXAMPLE_FILE);
        endif;
    endif;

    // Close the file.
    CloseFile (nvFileHandle);

```

```
end;
```

## CreateInstallationInfo

In an event-based script, the **CreateInstallationInfo** function is called automatically after the First UI Before event. It uses the system variables [IFX\\_KEYPATH\\_PRODUCT\\_INFO](#) and [IFX\\_PRODUCT\\_KEY](#) to create an application information key and a per application paths key for the program you are installing. The application information key is created immediately as a result of calling CreateInstallationInfo. The per application paths key is not created until a subsequent call to RegDBSetItem sets a [Path] or [DefaultPath] value under that key.

CreateInstallationInfo provides the product name for display in the Welcome dialog as well as the company name, product name, and version number that MaintenanceStart uses to initialize the uninstallation log file. MaintenanceStart will fail if CreateInstallationInfo is not called before it in the script.

Call CreateInstallationInfo only once in a setup. If you are launching multiple installations using DoInstall, each installation can of course have its own call to CreateInstallationInfo.

CreateInstallationInfo is a special registry-related function, designed to work with certain predefined registry keys. For more information, see [Special Registry-Related Functions](#).

---

**Note** ▪ The InstallScript engine currently does not support writing or reading Add or Remove Programs information for a product in the 64-bit part of the registry. Therefore, using the REGDB\_OPTION\_WOW64\_64KEY option with the [REGDB\\_OPTIONS](#) system variable is not supported for this registry function. Enabling the REGDB\_OPTION\_WOW64\_64KEY option has no effect on where registry entries are created by this function.

### Syntax

```
CreateInstallationInfo ( );
```

### Parameters

None

## Return Values

**Table 80** ▪ CreateInstallationInfo Return Values

| Return Value | Description                                                                                                                                                                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function was successful.                                                                                                                                                                                                               |
| < 0          | Indicates that the function failed to create one or more of the registry keys<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

- You must call CreateInstallationInfo before calling [RegDBSetItem](#) or [RegDBGetItem](#). See the descriptions of those functions for further information.
- The per application paths key is not actually created until RegDBSetItem is called to set a value under that key.
- CreateInstallationInfo no longer fails when IFX\_COMPANY\_NAME, IFX\_PRODUCT\_NAME, or IFX\_PRODUCT\_VERSION are empty. CreateInstallationInfo fails if a remote registry is connected, IFX\_KEYPATH\_PRODUCT\_INFO is empty, or the application information registry key cannot be created.

# CreateObject

**Project** ▪ In InstallScript projects, the **CreateObject** function has been replaced by the [CoCreateObject](#).

The **CreateObject** function initializes the registered COM object named by szProgID and returns a reference that can be assigned to a variable of type OBJECT by using the set keyword.

To check whether the object was initialized successfully, you can use the keywords try-catch-endcatch for more control over exception handling for COM objects.

**Note** ▪ The COM object must be registered on the target system in order for CreateObject to work.

## Syntax

```
CreateObject ( szProgID );
```

## Parameters

**Table 81** ▪ CreateObject Parameters

| Parameter       | Description                                               |
|-----------------|-----------------------------------------------------------|
| <b>szProgID</b> | Specifies the ProgID of the COM object to be initialized. |

## Return Values

A reference that can be assigned to a variable of type OBJECT by using the set keyword.

# CreateProgramFolder

The **CreateProgramFolder** function creates a new folder on the target system. The folder is created in the Start Programs menu.

## Syntax

```
CreateProgramFolder ( szFolderName );
```

## Parameters

**Table 82** ▪ CreateProgramFolder Parameters

| Parameter           | Description                                                   |
|---------------------|---------------------------------------------------------------|
| <b>szFolderName</b> | Specifies the name of the folder to add to the target system. |

## Return Values

**Table 83** ▪ CreateProgramFolder Return Values

| Return Value  | Description                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully added the folder to the target system or that the folder already existed. |
| <b>&lt; 0</b> | Indicates that the function was unable to add the specified program folder.                                        |

## CreateProgramFolder Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the CreateProgramFolder function.
 *
 * This script creates a program folder named ExampleFolder on
 * the target system.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_CreateProgramFolder(HWND);

function ExFn_CreateProgramFolder(hMSI)
    STRING  szFolderName, szTitle, szMsg;
begin

    // Set up parameters for call to CreateProgramFolder.
    szFolderName = "ExampleFolder";
    szTitle      = "CreateProgramFolder";
  
```

```

    szMsg          = "%s created successfully.";

    // Create the program folder.
    if (CreateProgramFolder (szFolderName) < 0) then
        MessageBox ("Unable to create program folder", SEVERE);
    else
        sprintfBox (INFORMATION, szTitle, szMsg, szFolderName);
    endif;

end;

```

## CreateRegistrySet

The **CreateRegistrySet** function creates the registry entries specified by one or all registry sets in the current media that are *not* associated with a particular component. (The name of the current media is stored in the system variable **MEDIA**.)

It is not necessary to call **CreateRegistrySet** for registry sets that are associated with one or more components since this function has no effect on these registry sets. Registry entries stored in registry sets that are associated with components are created when the component itself is installed (for example, via a **FeatureTransferData** call).

**Note** - When you enable the **REGDB\_OPTION\_WOW64\_64KEY** option, this affects where registry entries from registry sets are created. For example, if this option is enabled when you call the **CreateRegistrySet** function, the registry set is created in the 64-bit part of the registry. Note that this includes the default registry set which is created during file transfer immediately after the **OnMoving** event returns, and registry sets associated with components which are automatically created when the component is installed. Therefore, to avoid the data from these registry sets being created in the 64-bit portion of the registry unintentionally, it is recommended that you set this option only during the calling of the appropriate registry APIs in your script, then disable the option before continuing with the script.

### Syntax

```
CreateRegistrySet (szRegistrySet);
```

## Parameters

**Table 84** • CreateRegistrySet Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| szRegistrySet | Specifies the name of a registry set that is <i>not</i> associated with a particular component in the current media. To create all registry sets that are defined in the current media and are not associated with a particular component, pass a null string ("") in this parameter. |

## Return Values

**Table 85** • CreateRegistrySet Return Values

| Return Value | Description                                       |
|--------------|---------------------------------------------------|
| 0            | Indicates that the function was successful.       |
| < 0          | Indicates that an unspecified error has occurred. |

## Additional Information

- The value of the system variable MEDIA is set to 'DATA' during setup initialization. If you change the value of this variable to refer to a script-created feature set, you must change the value back to 'DATA' before calling **CreateRegistrySet**.
- If a registry set is associated only with components that are not included in the built media (because either they are not included in any features, they are included only in features whose Include in Build property is set to No, or they are included only in features that you have excluded from the built media using the Release Wizard's Features panel), the registry set's entries are not automatically created during file transfer and can be installed by a call to **CreateRegistrySet**.

## CreateRegistrySet Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the CreateShellObjects and CreateRegistrySet
 * functions.
 *
 * Note: To run this example, you must create a project that
 *       specifies registry entries and shell objects in the
 *       Resources pane of the IDE.
 *
 \*-----*/

export prototype ExFn_CreateRegistrySet(HWND);

```

```

function ExFn_CreateRegistrySet(hMSI)
    NUMBER ndisk;
    STRING szPassword;
    STRING svDir;
begin

    // Set the default target for copying files.
    svDir = "C:\\temp";

    // Get a target location from the user.
    AskDestPath ("", "", svDir, 0);

    // Assign the specified target location to
    // the corresponding system variable.
    INSTALLDIR = svDir;

    // Enable the progress indicator.
    SetStatusWindow (0, "");
    Enable (STATUS);
    StatusUpdate (ON, 100);

    // Transfer files.
    if (ComponentMoveData (MEDIA,ndisk,0) < 0 ) then
        MessageBox ("Error in moving data", SEVERE);
        abort;
    endif;

    // Create the Registry sets that were defined in the Resources pane.
    if (CreateRegistrySet ("") < 0) then
        MessageBox ("Unable to create registry set.", SEVERE);
        abort;
    endif;

    // Create the Shell objects that were defined in the Resources pane.
    if (CreateShellObjects ("") < 0) then
        MessageBox ("Unable to create shell objects.", SEVERE);
        abort;
    endif;

end;

```

## CreateShellObjects

The **CreateShellObjects** function creates shortcuts that are included in the current media, but are *not* associated with a particular component. The function also creates the folders that contain the created shortcuts if they do not already exist on the target system. (The name of the current media is stored in the system variable **MEDIA**.)

It is not necessary to call CreateShellObjects for shortcuts that are associated with one or more components because this function has no effect on these shortcuts. Shortcuts that are associated with components are created when the component itself is installed (for example, via a **FeatureTransferData** call). When the shortcuts are created, the folders containing the shortcuts will also be created, if necessary.

**Caution** ▪ This function will have no effect if called from an *InstallShield* object's script. The creation of shell objects is not supported in an *InstallShield* Object project.

**Note** ▪ *CreateShellObjects* will not create an empty folder on the target system: If a folder in the *Shortcuts* view is empty, this function will not create it. This restriction also applies to the shortcuts and corresponding folders that are automatically created when you call *FeatureTransferData*. To create an empty folder, call the *CreateProgramFolder* function in your script.

Syntax

CreateShellObjects (szReserved);

Parameters

Table 86 ▪ CreateShellObjects Parameters

| Parameter  | Description                                                            |
|------------|------------------------------------------------------------------------|
| szReserved | Pass a null string ("" ) in this parameter. No other value is allowed. |

Return Values

Table 87 ▪ CreateShellObjects Return Values

| Return Value | Description                                       |
|--------------|---------------------------------------------------|
| 0            | Indicates that the function was successful.       |
| < 0          | Indicates that an unspecified error has occurred. |

Additional Information

The value of the system variable MEDIA is set to 'DATA' during setup initialization. If you change the value of this variable to refer to a script-created component set, you must change the value back to 'DATA' before calling CreateShellObjects.

This function should be called only after FeatureTransferData has been called.

CreateShellObjects Example

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CreateShellObjects and CreateRegistrySet
```

```

* functions.
*
* Note: To run this example, you must create a project that
*       specifies registry entries and shell objects in the
*       Resources pane of the IDE.
*
\*-----*/

export prototype ExFn_CreateShellObjects(HWND);

function ExFn_CreateShellObjects(hMSI)
    NUMBER ndisk;
    STRING szPassword;
    STRING svDir;
begin

    //Set the default target for copying files.
    svDir = "C:\\temp";

    // Get a target location from the user.
    AskDestPath (""," ",svDir,0);

    // Assign the specified target location to
    // the corresponding system variable.
    INSTALLDIR = svDir;

    // Enable the progress indicator.
    SetStatusWindow (0, "");
    Enable (STATUS);
    StatusUpdate (ON, 100);

    // Transfer files.
    if (ComponentMoveData (MEDIA,ndisk,0) < 0 ) then
        MessageBox ("Error in moving data",SEVERE);
        abort;
    endif;

    //Create the Registry sets that were defined in the Resources pane.
    if (CreateRegistrySet ("") < 0) then
        MessageBox ("Unable to create registry set.",SEVERE);
        abort;
    endif;

    //Create the Shell objects that were defined in the Resources pane.
    if (CreateShellObjects ("") < 0) then
        MessageBox ("Unable to create shell objects.",SEVERE);
        abort;
    endif;

end;

```

## CreateShortcut

The **CreateShortcut** function lets you perform tasks such as the following:

- Add a shortcut or program folder to locations such as the Start menu, the Programs menu, or the desktop. Use the `szShortcutFolder` parameter to specify the appropriate location for the shortcut.
- Create a cascading submenu on the Startup menu, and include a shortcut in the submenu.
- Set Windows Shell properties for a shortcut to configure behavior such as disabling the ability to pin the shortcut to the Start menu.

---

**Note** ▪ The shortcut target must be present on the target system before **CreateShortcut** can be called.

**CreateShortcut** does not support the creation of Internet shortcuts.

## Syntax

CreateShortcut (szShortcutFolder, szName, szCommandLine, szWorkingDir, szIconPath, nIcon, szShortCutKey, nFlag);

## Parameters

**Table 88** • CreateShortcut Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szShortcutFolder</b> | <p>Specify the name of the folder that should contain the shortcut, or specify the name of the program folder that you want to create. If the folder does not exist, the installation creates it. For this parameter, you can specify a subfolder in a multi-level cascading menu. If the subfolder does not exist, <b>CreateShortcut</b> creates the subfolder and, if necessary, its parent folders.</p> <p>To add the shortcut to a specific folder, specify the fully qualified path—for example:</p> <pre>C:\ProgramData\Microsoft\Windows\Start Menu\Programs</pre> <p>To add a shortcut to the Programs menu on the Start menu, you can pass a null string ("") in this parameter.</p> <p>You can pass one of the following InstallScript system variables in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FOLDER_DESKTOP</b>—Adds the shortcut to the desktop.</li> <li>● <b>FOLDER_STARTUP</b>—Adds the shortcut to the Startup menu.</li> <li>● <b>FOLDER_STARTMENU</b>—Adds the shortcut to the Start menu.</li> <li>● <b>FOLDER_PROGRAMS</b>—Adds the shortcut to the Start\Programs menu.</li> </ul> <p>You can also specify a path relative to a folder that is identified by an InstallScript system variable—for example:</p> <pre>FOLDER_PROGRAMS ^ "ACCESSORIES\GAMES"</pre> |
| <b>szName</b>           | <p>Specify the name of the shortcut. Calling <b>CreateShortcut</b> to add a shortcut to a program folder also creates a link file in the links directory that is specified by szCommandLine. Note that Windows Shell does not allow the following characters in names: /, \, :, ?, &lt;, &gt;, or  .</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>szCommandLine</b>    | <p>Specify one of the following:</p> <ul style="list-style-type: none"> <li>● The fully qualified name of the executable file that is associated with the shortcut, including any command-line parameters. This is added to the Target value on the shortcut's Properties dialog box. To add a shortcut to the Start Programs menu, enter the fully qualified path of the links directory, which is where your application stores its icon link files.</li> <li>● The fully qualified path if szName is a subfolder.</li> </ul> <div style="text-align: center;">  </div> <p><b>Caution</b> • If the command line includes a long file name, it must be enclosed in quotes. Command-line parameters, however, should not be surrounded with quotation marks. For that reason, it is advisable to build the szCommandLine string from two separate strings.</p>                                                                                                                                                                                                                                                                                                                                                                 |

**Table 88** ▪ CreateShortcut Parameters (cont.)

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szWorkingDir</b>  | <p>Specify the working directory for the shortcut target.</p> <p>If szName is a subfolder, this parameter is not applicable.</p> <p><b>CreateShortcut</b> writes this directory in the Start In box on the Shortcut tab of the shortcut's Properties dialog box. If you pass a null string ("") in this parameter, the function leaves this Start In box blank, and the path in the Target box is used.</p> <hr/>  <p><b>Caution</b> ▪ Do not call <b>LongPathToQuote</b> to enclose this path in quotation marks. InstallShield automatically encloses these paths in quotation marks.</p> |
| <b>szIconPath</b>    | <p>Specify the fully qualified path to the file that contains the icon that you want to be displayed for the shortcut.</p> <p>If szItemName is a subfolder, this parameter is not applicable.</p> <hr/>  <p><b>Caution</b> ▪ Do not call <b>LongPathToQuote</b> to enclose this path in quotation marks. InstallShield automatically encloses these paths in quotation marks.</p>                                                                                                                                                                                                           |
| <b>nlcon</b>         | <p>Specify the icon index in the executable file that is specified by szIconPath. An icon index of 0 refers to the first icon in the file, an icon index of 1 refers to the second icon, and so on. If you are not using an icon, specify 0 in this parameter.</p> <p>If szName is a subfolder, this parameter is not applicable.</p>                                                                                                                                                                                                                                                                                                                                        |
| <b>szShortCutKey</b> | <p>Specify the shortcut key (in the form of a string) that you want to be assigned to your shortcut. You can set szShortCutKey for the shortcut so that end users can press the appropriate hot keys to launch the shortcut.</p> <p>For example, if you want end users to be able to launch the product by pressing the CTRL key, the ALT key, and then the 1 key on the numeric keyboard, pass "Ctrl + Alt + 1" in this parameter.</p> <p>If szName is a subfolder, this parameter is not applicable.</p>                                                                                                                                                                   |

**Table 88** • CreateShortcut Parameters (cont.)

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nFlag</b> | <p>Pass one or more of the following predefined constants in this parameter. To pass two or more predefined constants in this parameter, combine those constants with the bitwise OR operator (   ).</p> <ul style="list-style-type: none"> <li>● <b>CS_OPTION_FLAG_REPLACE_EXISTING</b>—Replace an existing shortcut.</li> <li>● <b>CS_OPTION_FLAG_RUN_MAXIMIZED</b>—The target of the shortcut is maximized when launched.</li> <li>● <b>CS_OPTION_FLAG_RUN_MINIMIZED</b>—The target of the shortcut is minimized when launched.</li> <li>● <b>CS_OPTION_FLAG_PREVENT_PINNING</b>—Do not allow the shortcut to be pinned to the Start menu or taskbar on Windows 7 or later systems. This option hides the context menu commands that enable end users to pin the shortcut to the taskbar and to the Start menu.<br/><br/>You may want to prevent pinning for shortcuts that are for tools and secondary products that are part of your installation.</li> <li>● <b>CS_OPTION_FLAG_NO_NEW_INSTALL_HIGHLIGHT</b>—Do not highlight the shortcut as newly installed after end users install your product on Windows 7 or later systems. This has the same effect as clearing the <b>Highlight newly installed programs</b> check box in the Customize Start Menu dialog box for an individual item on a target system.<br/><br/>You may want to use this option for shortcuts that are for tools and secondary products that are part of your installation.</li> <li>● <b>CS_OPTION_FLAG_NO_STARTSCREEN_PIN</b>—Do not pin the shortcut to the Start screen by default on Windows 8 target systems. If you pass this constant, the installation sets a Windows Shell property that was introduced in Windows 8.<br/><br/>You may want to prevent pinning for shortcuts that are for tools and secondary products that are part of your installation.</li> <li>● <b>NULL</b>—Indicates no options.</li> </ul> <p>For more information on CS_OPTION_FLAG_PREVENT_PINNING and CS_OPTION_FLAG_NO_STARTSCREEN_PIN, see the <a href="#">Additional Information section</a>.</p> |

## Return Values

**Table 89** • CreateShortcut Return Values

| Return Value | Description                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully added or replaced the shortcut in the specified folder and associated the executable file with it.                                                                                                                                                        |
| < 0          | <p>Indicates that the function was unable to add or replace the shortcut and associate the executable file with it.</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

## Additional Information

Note the following details about two of the nFlag constants.

### CS\_OPTION\_FLAG\_PREVENT\_PINNING

If you configure the shortcut to prevent pinning to the taskbar and the Start menu, the target of the shortcut is ineligible for inclusion in the most frequently used list on the Start menu.

Shortcuts that contain certain strings cannot be pinned to the taskbar or the Start menu, and they cannot be displayed in the most frequently used list. Examples are:

- Documentation
- Help
- Install
- Remove
- Setup
- Support

### CS\_OPTION\_FLAG\_NO\_STARTSCREEN\_PIN

Note that Windows 8 maintains information about shortcut pinning to the Start screen after a shortcut is removed by uninstalling the application. Therefore, the CS\_OPTION\_FLAG\_NO\_STARTSCREEN\_PIN constant has no effect on the target system if the shortcut has already been installed on it. Thus, when you are testing this functionality, ensure that you test on a clean machine—one on which this shortcut and its target have never been installed.

## CreateShortcut Examples

The following examples demonstrate how to use **CreateShortcut**:

- [Place a shortcut to an executable file on the Start menu and the Start Programs menu.](#) (**CreateShortcut** Example 1)
- [Create a cascading submenu on the Startup menu and add a shortcut to the menu.](#) (**CreateShortcut** Example 2)

- Place a subfolder on the desktop and a shortcut pointing to an executable file in the new folder.  
(CreateShortcut Example 3)

## CreateShortcut Example 1

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CreateShortcut function.
*
* This example places a shortcut to an executable file on the
* Start menu and the Start Programs menu.
*
* Note: Before running this script, set the preprocessor
*       constants so that they reference the fully qualified
*       names of the Windows Notepad executable file and
*       a valid text file on the target system.
*
\*-----*/

#define PROGRAM "C:\\Windows\\Notepad.exe"
#define PARAM   "C:\\Windows\\Readme.txt"

function OnFirstUIAfter()
    STRING szShortcutFolder, szName, szCommandLine, szWorkingDir;
    STRING szShortCutKey, szProgram, szParam, szIconPath;
    NUMBER nIcon;
begin

    // Set up parameters for call to CreateShortcut.
    szShortcutFolder = FOLDER_STARTMENU;
    szName           = "Notepad Example 1";
    szProgram        = PROGRAM;
    szParam          = PARAM;

    LongPathToQuote (szProgram, TRUE);

    LongPathToShortPath (szParam);

    szCommandLine = szProgram + " " + szParam;
    szWorkingDir   = "";
    szIconPath     = "";
    nIcon          = 0;
    szShortCutKey  = "";

    // Add a shortcut to the Start menu.
    if (CreateShortcut (szShortcutFolder, szName, szCommandLine, szWorkingDir, szIconPath,
                       nIcon, szShortCutKey, CS_OPTION_FLAG_REPLACE_EXISTING) < 0) then
        MessageBox ("CreateShortcut failed.", SEVERE);
```

```

else
    sprintfBox (INFORMATION, "CreateShortcut", "%s created successfully.",
                szName);
endif;

szShortcutFolder = "";
szName           = "Another Notepad Example";

// Add a shortcut to the Programs menu.
if (CreateShortcut (szShortcutFolder, szName, szCommandLine, szWorkingDir, szIconPath,
                    nIcon, szShortCutKey, CS_OPTION_FLAG_REPLACE_EXISTING) < 0) then

```

## CreateShortcutFolder

The **CreateShortcutFolder** function creates a new folder on the target system. The folder is created on the Start Programs menu. If the folder already exists, it is highlighted.

### Syntax

```
CreateShortcutFolder (szShortcutFolder);
```

## Parameters

**Table 90** ▪ CreateShortcutFolder Parameters

| Parameter               | Description                                                 |
|-------------------------|-------------------------------------------------------------|
| <b>szShortcutFolder</b> | Specify the name of the folder to add to the target system. |

## Return Values

**Table 91** ▪ CreateShortcutFolder Return Values

| Return Value  | Description                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully added the folder to the target system or that the folder already existed. |
| <b>&lt; 0</b> | Indicates that the function was unable to add the specified program folder.                                        |

## CreateShortcutFolder Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CreateShortcutFolder function.
*
* This script creates a program folder named ExampleFolder
* on the target system.
*
\*-----*/

function OnFirstUIAfter()
    STRING  szShortcutFolder, szTitle, szMsg;
begin

    // Set up parameters for call to CreateShortcutFolder.
    szShortcutFolder = "ExampleFolder";
    szTitle          = "CreateShortcutFolder";
    szMsg            = "%s created successfully.";

    // Create the program folder.
    if (CreateShortcutFolder (szShortcutFolder) < 0) then
        MessageBox ("Unable to create program folder", SEVERE);
    else
        sprintfBox (INFORMATION, szTitle, szMsg, szShortcutFolder);
    endif;
```

```
end;
```

## CtrlClear

The **CtrlClear** function clears the contents of various controls; it deletes the contents of a single- or multi-line edit field, static text field, single- or multi-selection list box, or the edit field of a combo box in a custom dialog.

### Syntax

```
CtrlClear ( szDialogName, nControlID );
```

### Parameters

**Table 92** ▪ CtrlClear Parameters

| Parameter           | Description                                                               |
|---------------------|---------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of the dialog that contains the control to be deleted. |
| <b>nControlID</b>   | Specifies the control ID of the dialog identified by szDialogName.        |

### Return Values

**Table 93** ▪ CtrlClear Return Values

| Return Value  | Description                                                           |
|---------------|-----------------------------------------------------------------------|
| <b>0</b>      | CtrlClear successfully deleted the contents of the specified control. |
| <b>&lt; 0</b> | CtrlClear was unable to delete the contents of the dialog.            |

## CtrlClear Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlClear, CtrlGetText, and CtrlSetText
* functions.
*
```

```

* This example script displays a custom dialog that contains
* edit boxes for a user name, company name, and serial number.
* It also contains three buttons: Clear All, Done, and Cancel.
* On initialization of the dialog, the script calls
* CtrlSetText to place default text into each edit control.
*
* Button Operations
*
* Clear All      Calls CtrlClear to clear all edit boxes.
*
* Done           Calls CtrlGetText to retrieve edit box values.
*               If all fields contain data, the dialog
*               closes and the values from the edit boxes are
*               displayed in a message box.
*
* Cancel        Closes the dialog. Edit box values are
*               not retrieved or displayed.
*
* The "custom" dialog used in this script is actually the
* Sd dialog that is displayed by the built-in function
* SdRegisterUserEx. Because this dialog is stored
* in the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*

        "Name: %s\n\nCompany: %s\n\nSerial: %s",
        svName, svCompany,svSerial);
endif;

end;

```

## CtrlDir

The **CtrlDir** function fills a list box or a combo box control with a file listing that matches the specified path or file name in szDir. You can include names of files, subdirectories, and disk drives in the listing. The CtrlDir function works only with custom dialogs.

### Syntax

```
CtrlDir ( szDialogName, nControlID, szDir, nItems );
```

## Parameters

**Table 94** ▪ CtrlDir Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a dialog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>nControlID</b>   | Specifies the resource ID of the list box or combo box control.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>szDir</b>        | Specifies the fully qualified path or file name, which may include wildcard characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>nItems</b>       | <p>Specifies the type of listing to display in the control. Pass one or more of the following predefined constants in this parameter. To include more than one type of element, combined these constants with the bitwise OR operator ( ):</p> <ul style="list-style-type: none"> <li>• <b>DLG_DIR_FILE</b>—Creates a list of files matching the file specification szDir.</li> <li>• <b>DLG_DIR_DIRECTORY</b>—Creates a list of subdirectories that exist in the path specification szDir.</li> <li>• <b>DLG_DIR_DRIVE</b>—Creates a list of drives.</li> </ul> |

## Return Values

**Table 95** ▪ CtrlDir Return Values

| Return Value  | Description                                                    |
|---------------|----------------------------------------------------------------|
| <b>0</b>      | CtrlDir successfully filled the specified control in a dialog. |
| <b>&lt; 0</b> | CtrlDir was unable to fill the specified control.              |

## CtrlDir Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
```

```

* Demonstrates the CtrlDir function.
*
* This example script displays a file listing in a custom
* dialog. The directory listing is created by a call to
* CtrlDir, which builds the list and places it into the
* custom dialog's list box control. The user can then select
* an item from the list with the keyboard or mouse. If the
* dialog is closed with the Next button, the selected item
* is displayed in a message box.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdSetupTypeEx. Because this dialog is stored
* in the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*

```

## CtrlGetCurSel

The **CtrlGetCurSel** function retrieves the currently selected item from a single-selection list box or combo box control in a custom dialog. Call **CtrlGetMultCurSel** to retrieve items from multi-selection list boxes.

### Syntax

```
CtrlGetCurSel ( szDialogName, nControlID, svText );
```

## Parameters

**Table 96** ▪ CtrlGetCurSel Parameters

| Parameter           | Description                                                                      |
|---------------------|----------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a custom dialog that contains the item to be retrieved.    |
| <b>nControlID</b>   | Specifies the resource ID of the single-selection list box or combo box control. |
| <b>svText</b>       | Returns the item currently selected with the control specified by nControlID.    |

## Return Values

**Table 97** ▪ CtrlGetCurSel Return Values

| Return Value  | Description                                                                       |
|---------------|-----------------------------------------------------------------------------------|
| <b>0</b>      | CtrlGetCurSel successfully retrieved the currently selected item from the dialog. |
| <b>&lt; 0</b> | CtrlGetCurSel was unable to retrieve the selected item.                           |

## CtrlGetCurSel Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlGetCurSel and CtrlSetCurSel functions.
*
* This example script displays a custom dialog that has an
* edit box and a list box. After the dialog is initialized,
* the script places the names of folders that reside in the
* root of the Windows disk into the dialog's list box. It
* then calls CtrlSetCurSel to make "Windows" the selected folder.
*
* Each time the user selects a folder name from the list box,
* the script calls CtrlGetCurSel to get the selected item so
* that it can be placed into the edit box. When the dialog
* is closed with the Done button, the currently selected item
* is displayed in a message box.
```

```

*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdSelectFolder. Because this dialog is stored
* in the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*

// display the selected item.
if (nCmdValue = RES_PBUT_NEXT) then
    MessageBox ("You selected " + svSelection + ".", INFORMATION);
endif;

end;

```

## CtrlGetDlgItem

The **CtrlGetDlgItem** function retrieves the window handle of a control in a custom dialog. **CtrlGetDlgItem** is similar to the Windows API **GetDlgItem**, except that with **CtrlGetDlgItem**, you can specify the InstallScript dialog name instead of the dialog's window handle.

### Syntax

```
CtrlGetDlgItem (byval string szDialogName, byval HWND hDialog, byval number nCtrlId);
```

## Parameters

**Table 98** • CtrlGetDlgItem Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specify the name of the dialog that contains the control whose handle is being retrieved. The dialog must already exist when the function is called.<br><br>If hDialog is not a null string (""), you can specify a null string for szDialogName.                                                           |
| <b>hDialog</b>      | Specify the window handle of the dialog that contains the control whose handle is being retrieved. The dialog must already exist when the function is called.<br><br>If you specify a string (""), <b>CtrlGetDlgItem</b> determines the dialog's handle by calling <b>CmdGetHwndDlg</b> using szDialogName. |
| <b>nCtrlId</b>      | Specify the ID of the control whose window handle you want to retrieve.                                                                                                                                                                                                                                     |

## Return Values

**CtrlGetDlgItem** returns the window handle of the control or NULL if the control does not exist or an error occurred. **GetExtendedErrInfo** may return additional error information.

## Additional Information

If you are making multiple calls to **CtrlGetDlgItem** to look up multiple controls, it is recommended that you call **CmdGetHwndDlg** to get the handle of the dialog and pass it to each function call. If you are looking up the window handle of a single control, it is recommended that you specify the dialog name and specify hDialog as a null string ("").

# CtrlGetMLEText

The **CtrlGetMLEText** function retrieves the contents of a multi-line edit field control in a custom dialog. InstallShield places each line of the multi-line edit field into a string list identified by listID. Call **CtrlGetText** to retrieve the contents of a single-line edit field control.

## Syntax

```
CtrlGetMLEText ( szDialogName, nControlID, listID );
```

## Parameters

**Table 99** ▪ CtrlGetMLEText Parameters

| Parameter           | Description                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a custom dialog that contains the multi-line edit control whose contents are to be retrieved.                                                                              |
| <b>nControlID</b>   | Specifies the resource ID of the multi-line edit control.                                                                                                                                        |
| <b>listID</b>       | Returns a string list of the lines in the edit field identified by nControlID. The string list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> . |

## Return Values

**Table 100** ▪ CtrlGetMLEText Return Values

| Return Value  | Description                                                                    |
|---------------|--------------------------------------------------------------------------------|
| <b>0</b>      | CtrlGetMLEText successfully retrieved the contents of a multi-line edit field. |
| <b>&lt; 0</b> | CtrlGetMLEText was unable to retrieve the contents of the control.             |

## CtrlGetMLEText Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlSetMLEText and CtrlGetMLEText functions.
*
* This example script displays a custom dialog that contains
* a multi-line edit box. The script creates a list of all
* program folders on the target system and then calls
* CtrlSetMLEText to place that list into the dialog's multi-
* line edit box. The dialog also contains a Save button that
* enables the end user to save the folder names to a text file.
* When that option is selected, the script calls CtrlGetMLEText
* to get the folder names from the multi-line edit box.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdShowInfoList. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
```

```

* dialog.
*
* Notes: The multi-line edit box is defined as read-only
*       in the resource; its contents cannot be edited.
*
*       The script changes the static text of the dialog
*       box's Next button and disables the Back button in order
*       to make the dialog fit the needs of the example.
*
*       The function GetGroupNameList may return an error
*       if the target system is running under a shell other
*       than the Explorer shell.
*

end;

```

# CtrlGetMultCurSel

The **CtrlGetMultCurSel** function retrieves the currently selected lines from a multi-selection list box control, that is, a list box control with the LBS\_MULTIPLESEL style. (This function does not support extended selection list box controls, that is, list box controls with the LBS\_EXTENDEDSEL style.) Each selected line of the multi-selection list box is placed into a string list identified by listID. To retrieve selected text from a single-selection list box control, call **CtrlGetCurSel**. CtrlGetMultCurSel is for use only with custom dialogs.

## Syntax

```
CtrlGetMultCurSel ( szDialogName, nControlID, listID );
```

## Parameters

**Table 101** ▪ CtrlGetMultCurSel Parameters

| Parameter           | Description                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a custom dialog that contains the list box control whose contents are to be retrieved.                                                                  |
| <b>nControlID</b>   | Specifies the resource ID of the multi-line edit control.                                                                                                                     |
| <b>listID</b>       | Returns the lines of the list box identified by nControlID. The string list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> . |

## Return Values

**Table 102** ▪ CtrlGetMultCurSel Return Values

| Return Value  | Description                                                            |
|---------------|------------------------------------------------------------------------|
| <b>0</b>      | CtrlGetMultCurSel successfully retrieved the currently selected items. |
| <b>&lt; 0</b> | CtrlGetMultCurSel was unable to retrieve the items.                    |

## CtrlGetMultCurSel Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlSetMultCurSel and CtrlGetMultCurSel
* functions.
*
* This script retrieves the names of all program folders
* on the target system and places them in a list. When the
* dialog is initialized, the CtrlSetList function sets this
* list to be displayed in the list box. The CtrlSetMultCurSel
* function is then called to highlight the user-selected
* folder.
*
* This list is then destroyed. A new list is created when the
* Next button is clicked. CtrlGetMultCurSel then retrieves the
* elements in the list box and assigns them to this new string
* list. This list is then displayed in an Sd dialog.
*
* Note: In order for this script to run properly, you must set
* the RES_DIALOG_ID and RES_DIALOG_LISTBOX constants to a
* dialog and list box created in _isuser.dll.
*
* The GetGroupNameList function used in this example may
* return an error if the target system is running under a
* shell other than Explorer.
*

szMsg  = "The following are the elements highlighted in the list box:";

// Display the list of elements highlighted.
SdShowInfoList (szTitle, szMsg, listFolders);

// Remove listFolders string list from memory.
ListDestroy (listFolders);
MessageBox ("listFolders destroyed.", INFORMATION);

// Close the dialog.
EndDialog (szDialogName);

// Remove the dialog from memory.
ReleaseDialog (szDialogName);

end;

```

# CtrlGetState

The **CtrlGetState** function gets the current state of a check box or option button control from a custom dialog.

## Syntax

```
CtrlGetState ( szDialogName, nControlID );
```

## Parameters

**Table 103** ▪ CtrlGetState Parameters

| Parameter           | Description                                                                                         |
|---------------------|-----------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of the dialog that contains the control.                                         |
| <b>nControlID</b>   | Specifies the resource ID of the check box or option button control whose state is to be retrieved. |

## Return Values

**Table 104** ▪ CtrlGetState Return Values

| Return Value                    | Description                                                    |
|---------------------------------|----------------------------------------------------------------|
| <b>BUTTON_CHECKED (-1001)</b>   | The check box or option button is selected.                    |
| <b>BUTTON_UNCHECKED (-1002)</b> | The check box or option button is not selected.                |
| <b>DLG_ERR (-1)</b>             | CtrlGetState was unable to determine the state of the control. |

## CtrlGetState Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlGetState and CtrlSetState functions.
*
* This example script displays a custom dialog that contains
* four check boxes. The script calls CtrlSetState to set the
* first two check boxes to checked. The last two are unchecked
* by default. When the end user clicks the Next button, the
```

```

* script calls CtrlGetState to retrieve the state of each
* each check box. The script then displays a message box that
* reports which check boxes were checked.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdAskOptions. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
\*-----*/

// If fourth option is selected, add line to message.
if (CtrlGetState (szDialogName, ID_OP4_CHECK) = BUTTON_CHECKED) then
    szMsg = szMsg + "Option 4\n";
endif;
endif;

// Close the custom dialog.
EndDialog (szDialogName);

// Remove the custom dialog from memory.
ReleaseDialog (szDialogName);

// Display message if dialog was closed with Next button.
if (nCmdValue = RES_PBUT_NEXT) then
    MessageBox (szMsg, INFORMATION);
endif;

end;

```

## CtrlGetSubCommand

The **CtrlGetSubCommand** function retrieves the action performed on a control in a custom dialog. For example, CtrlGetSubCommand can tell you if the user single-clicked or double-clicked a list box or combo box control. It can also tell you when the contents of an edit field have changed.

Advanced developers can call [CmdGetHwndDlg](#) to handle additional information.

### Syntax

```
CtrlGetSubCommand (szDialogName);
```

## Parameters

**Table 105** ▪ CtrlGetSubCommand Parameters

| Parameter           | Description                            |
|---------------------|----------------------------------------|
| <b>szDialogName</b> | Specifies the name of a custom dialog. |

## Return Values

**Table 106** ▪ CtrlGetSubCommand Return Values

| Return Value                  | Description                                |
|-------------------------------|--------------------------------------------|
| <b>EDITBOX_CHANGE (-1007)</b> | The contents of the edit box have changed. |
| <b>LISTBOX_ENTER (-1008)</b>  | The user double-clicked a list box item.   |
| <b>LISTBOX_SELECT (-1009)</b> | The user single-clicked a list box item.   |

## CtrlGetSubCommand Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlGetSubCommand function.
*
* This example script displays a list of program groups in
* the list box of a custom dialog. It then responds to events
* from the edit box and list box as follows:
*
* Single-click in list box: Selected item is put into edit box.
*
* Double-click in list box: Double-clicked item is stored for
*                           later display and dialog is closed.
*
* Change in edit box value: The default system sound is played.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdSelectFolder. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
\*-----*/
```

    bSelected = TRUE;
    bDone = TRUE;
case RES_PBUT_BACK:
    bDone = TRUE;
endswitch;

until bDone;

// Close the dialog.
EndDialog (szDialogName);

// Free the dialog from memory.
ReleaseDialog (szDialogName);

if bSelected then
    // Display the name of the selected folder.

```

```

        MessageBox ("You selected " + svSelection + ".", INFORMATION);
    endif;

end;

```

## CtrlGetText

The **CtrlGetText** function retrieves the text from an edit field, static text field, or button control of a custom dialog. To retrieve the text from multi-line edit field controls, call [CtrlGetMLEText](#).

### Syntax

```
CtrlGetText ( szDialogName, nControlID, svText );
```

### Parameters

**Table 107** ▪ CtrlGetText Parameters

| Parameter           | Description                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a dialog that contains the field or control whose text is to be retrieved. |
| <b>nControlID</b>   | Specifies the resource ID of the edit field, static text field, or button control.               |
| <b>svText</b>       | Returns the text from the control or field identified by nControlID.                             |

### Return Values

**Table 108** ▪ CtrlGetText Return Values

| Return Value  | Description                                                     |
|---------------|-----------------------------------------------------------------|
| <b>0</b>      | CtrlGetText successfully retrieved the contents of the control. |
| <b>&lt; 0</b> | CtrlGetText was unable to retrieve the contents.                |

## CtrlGetText Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
```

```

*
* InstallShield Example Script
*
* Demonstrates the CtrlSetText, CtrlGetText, and CtrlSelectText
* functions.
*
* This example script displays a custom dialog with two
* edit boxes to obtain a user name and company name. The
* script calls CtrlSetText to place initial values into the
* edit boxes and CtrlSelectText to select the contents of the
* first edit box. When the user clicks the Next button, the
* script calls CtrlGetText to retrieve the contents of the edit
* boxes so that they can be displayed in a message box after
* the custom dialog is closed.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdRegisterUser. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*

endif;

end;

```

## CtrlGetUrlForLinkClicked

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **CtrlGetUrlForLinkClicked** function retrieves the URL for a link that an end user clicked.

**Tip** ▪ To learn how to add links to dialogs in InstallScript and InstallScript MSI projects, see *Using an HTML Control on a Dialog*.

### Syntax

```
CtrlGetUrlForLinkClicked (byval string szDialogName, byval number nControlID, byref string svText);
```

## Parameters

**Table 109** ▪ CtrlGetUrlForLinkClicked Parameters

| Parameter           | Description                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specify the name of the dialog that contains the HTML control.                                                                           |
| <b>nControlID</b>   | Specify the control ID of the HTML control. This ID is the same as the ID of the static control that was converted into an HTML control. |
| <b>svText</b>       | Specify the string variable to return the link URL text.                                                                                 |

## Return Values

**Table 110** ▪ CtrlGetUrlForLinkClicked Return Values

| Return Value             | Description                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>ISERR_GEN_FAILURE</b> | <b>CtrlGetUrlForLinkClicked</b> was unable to determine the link that an end user clicked. This function returns this value if the specified control ID is not for an HTML control. |

## CtrlGetUrlForLinkClicked Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
//-----
//
//  InstallShield Example Script
//
//  Demonstrates how to use an HTML control with the
//  CtrlGetUrlForLinkClicked and CtrlSetText functions
//
//  To use this sample script:
//  1. Add a custom dialog to your project.
//  2. Add a static text control to the dialog.
//
//-----

#define MY_HYPERLINK1 1401

function MyCustomDialog(szTitle, szMsg)
    STRING  szDlg, szTemp, szUrl;
```

```

NUMBER  nId, nMessage, nTemp, nSdDialog;
HWND    hwndDlg;
BOOL    bDone;

begin

    // Specify a name to identify the custom dialog in this installation.
    szDlg = "CustomName";

    while (!bDone)

        nId = WaitOnDialog( szDlg );

        switch(nId)
        case DLG_INIT:
            // Initialize the back, next, and cancel button enable/disable states
            // for this dialog and replace %P, %VS, %VI with
            // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
            // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
            hwndDlg = CmdGetHwndDlg(szDlg);
            SdGeneralInit(szDlg, hwndDlg, 0, "");

            // Put the corresponding Info in the List Field
            if( szMsg != "" ) then
                SdSetStatic(szDlg, SD_STA_MSG, szMsg);
            endif;

            SdSetDlgTitle(szDlg, hwndDlg, szTitle);

            CtrlSetText(szDlg, MY_HYPERLINK1,
                "[html]<style type=\"text/css\">html,body {padding:0; margin:0;} *
                {font-size: 8pt; font-family: \"MS Sans Serif\";}</style>
                <a href=\"http://www.MyWebSite.com\">
                Visit my Web site</a>");

        case MY_HYPERLINK1:
            CtrlGetUrlForLinkClicked(szDlg, MY_HYPERLINK1, szUrl);
            MessageBox("Hyperlink clicked: " + szUrl, 0);

            // TO DO: Add additional case statements as needed.

        default:
            // check standard handling
            if (SdIsStdButton( nId ) && SdDoStdButton( nId )) then
                bDone = TRUE;
            endif;
        endswitch;

    endwhile;
end;

# CtrlPGroups

The **CtrlPGroups** function places a list of existing program folders in a list box or combo box control. This function is for use only with custom dialogs.

## Syntax

```
CtrlPGroups ( szDialogName, nControlID );
```

## Parameters

**Table 111** ▪ CtrlPGroups Parameters

| Parameter           | Description                                                             |
|---------------------|-------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a custom dialog that contains the control to use. |
| <b>nControlID</b>   | Specifies the resource ID of a list box or combo box control.           |

## Return Values

**Table 112** ▪ CtrlPGroups Return Values

| Return Value  | Description                                                                           |
|---------------|---------------------------------------------------------------------------------------|
| <b>0</b>      | CtrlPGroups successfully placed the specified list of program folders in the control. |
| <b>&lt; 0</b> | CtrlPGroups was unable to place the specified list of program folders in the control. |

## CtrlPGroups Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlPGroups function.
*
* This example script displays a custom dialog that has an
* edit box and a list box. After the dialog is initialized,
* the script calls CtrlPGroups to create a list of program
* folder names and place that list into the dialog's list box.
*
```

```

* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdSelectFolder. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
\*-----*/

endif;

```

end;

# CtrlSelectText

The **CtrlSelectText** function selects all the text in an edit field or the edit field of a combo box. If the control is a multi-line edit field, this function selects all the text on all lines. This function is for use only with custom dialogs.

## Syntax

CtrlSelectText ( szDialogName, nControlID );

## Parameters

Table 113 ▪ CtrlSelectText Parameters

| Parameter    | Description                                                                       |
|--------------|-----------------------------------------------------------------------------------|
| szDialogName | Specifies the name of a valid dialog that contains the edit field to be selected. |
| nControlID   | Specifies the resource ID of the edit field or combo box control to be selected.  |

## Return Values

Table 114 ▪ CtrlSelectText Return Values

| Return Value | Description                                                     |
|--------------|-----------------------------------------------------------------|
| 0            | CtrlSelectText successfully selected all the text in the field. |
| < 0          | CtrlSelectText was unable to select the text.                   |

## CtrlSelectText Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlSetText, CtrlGetText, and CtrlSelectText
* functions.
*
* This example script displays a custom dialog with two
```

```

* edit boxes to obtain a user name and company name. The
* script calls CtrlSetText to place initial values into the
* edit boxes and CtrlSelectText to select the contents of the
* first edit box. When the user clicks the Next button, the
* script calls CtrlGetText to retrieve the contents of the edit
* boxes so that they can be displayed in a message box after
* the custom dialog is closed.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdRegisterUser. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*

if nCmdValue = RES_PBUT_NEXT then
    MessageBox (svName + "\n" + svCompany, INFORMATION);

```

```
endif;

end;
```

## CtrlSetCurSel

The **CtrlSetCurSel** function searches the specified list or combo box control for a string. If the string is found, CtrlSetCurSel selects (highlights) the item. Call **CtrlSetMultCurSel** for multi-selection list box and combo box controls. The CtrlSetCurSel function is for use only with custom dialogs.

### Syntax

```
CtrlSetCurSel ( szDialogName, nControlID, szText );
```

### Parameters

**Table 115** ▪ CtrlSetCurSel Parameters

| Parameter           | Description                                                                           |
|---------------------|---------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a valid custom dialog that contains the control to be searched. |
| <b>nControlID</b>   | Specifies the resource ID of the control that contains the search string.             |
| <b>szText</b>       | Specifies the search string. If the string is found, it is selected (highlighted).    |

### Return Values

**Table 116** ▪ CtrlSetCurSel Return Values

| Return Value  | Description                                                         |
|---------------|---------------------------------------------------------------------|
| <b>0</b>      | CtrlSetCurSel successfully found and selected the specified string. |
| <b>&lt; 0</b> | CtrlSetCurSel was unable to find and select the specified string.   |

## CtrlSetCurSel Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

    MessageBox ("You selected " + svSelection + ".", INFORMATION);
endif;

end;

```

## CtrlSetFont

The **CtrlSetFont** function specifies a font for a control in a custom dialog. Call this function from within the DLG\_INIT routine of the dialog message processing loop.

### Syntax

```
CtrlSetFont ( szDialogName, hFont, nControlID );
```

## Parameters

**Table 117** ▪ CtrlSetFont Parameters

| Parameter           | Description                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a valid dialog.                                                                                                                                             |
| <b>hFont</b>        | Specifies the handle of a font that has been created by a call to GetFont                                                                                                         |
| <b>nControlID</b>   | Specifies the resource ID of the control whose font is to be set. To set the font for all the controls in the dialog, pass the predefined constant ALLCONTROLS in this parameter. |

## Return Values

**Table 118** ▪ CtrlSetFont Return Values

| Return Value  | Description                                                     |
|---------------|-----------------------------------------------------------------|
| <b>0</b>      | CtrlSetFont successfully set the requested font in a dialog.    |
| <b>&lt; 0</b> | CtrlSetFont was unable to set the font in the requested dialog. |

## CtrlSetFont Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the GetFont and CtrlSetFont functions.
*
* This example script calls GetFont to retrieve the handles
* of four fonts. These handles are then passed to CtrlSetFont
* to set the font of the static text fields in a custom dialog
* box.
*
* The "custom" dialog used in this script is actually the
* InstallShield dialog that is displayed by the built-in
* function SetupType. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
```

```

* dialog.
*

// Close the dialog
EndDialog (szDialogName);

// Free the dialog from memory
ReleaseDialog (szDialogName);

end;
```

## CtrlSetList

The **CtrlSetList** function places the contents of a string list into the specified single- or multi-selection list box or combo box control. Any pre-existing contents are replaced with the items contained in listID. InstallShield places each element of the string list into each element of the list box or combo box control.

### Syntax

```
CtrlSetList (szDialogName, nControlID, listID);
```

## Parameters

**Table 119** ▪ CtrlSetList Parameters

| Parameter           | Description                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a dialog that contains the list box or combo box.                                             |
| <b>nControlID</b>   | Specifies the resource ID of the list box or combo box.                                                             |
| <b>listID</b>       | Specifies the name of a string list that contains the elements to be copied into the list box or combo box control. |

## Return Values

**Table 120** ▪ CtrlSetList Return Values

| Return Value  | Description                                                                       |
|---------------|-----------------------------------------------------------------------------------|
| <b>0</b>      | CtrlSetList successfully placed the contents of the string list into the control. |
| <b>&lt; 0</b> | CtrlSetList was unable to place the contents of the string list into the control. |

## CtrlSetList Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlSetList function.
*
* This example script displays a custom dialog that
* contains a list box. After the dialog is initialized,
* the script calls CtrlSetList to place a list of
* InstallShield background color constants into the custom dialog's
* list box.
*
* The user can view the background that corresponds to a
* color constant either by double-clicking the constant or by
* selecting it and clicking the Set button.
*

```

```

* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdSetupTypeEx. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog. Note that the script changes the dialog's
* static text and disables the Back button to make the dialog
* meet the requirements of the example.
*

    SetColor (BACKGROUND, nColor);
end;

```

## CtrlSetMLEText

The **CtrlSetMLEText** function sets the text of a multi-line edit box control. InstallShield separately places each string in listID into the multi-line edit box control. This function is for use only with custom dialogs.

### Syntax

```
CtrlSetMLEText ( szDialogName, nControlID, listID );
```

## Parameters

**Table 121** ▪ CtrlSetMLEText Parameters

| Parameter           | Description                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a dialog.                                                                                     |
| <b>nControlID</b>   | Specifies the resource ID of the multi-line edit box control in the dialog.                                         |
| <b>listID</b>       | Specifies the name of a valid string list that contains the elements to be copied into the multi-line edit control. |

## Return Values

**Table 122** ▪ CtrlSetMLEText Return Values

| Return Value  | Description                                               |
|---------------|-----------------------------------------------------------|
| <b>0</b>      | CtrlSetMLEText set the text into the control.             |
| <b>&lt; 0</b> | CtrlSetMLEText was unable to set the text in the control. |

## CtrlSetMLEText Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlSetMLEText and CtrlGetMLEText functions.
*
* This example script displays a custom dialog that contains
* a multi-line edit box. The script creates a list of all
* program folders on the target system and then calls
* CtrlSetMLEText to place that list into the dialog's multi-
* line edit box. The dialog also has a Save button that
* enables the end user to save the folder names to a text file.
* When that option is selected, the script calls CtrlGetMLEText
* to get the folder names from the multi-line edit box.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdShowInfoList. Because this dialog is stored
* in the file _isres.dll, which is already compressed in
```

```

* the installation, it can be used in a script as a custom
* dialog.
*
* Notes: The multi-line edit box is defined as read-only
*       in the resource; its contents cannot be edited.
*
*       The script changes the static text of the dialog
*       box's Next button and disables the Back button to
*       make the dialog fit the needs of the example.
*
*       The function GetGroupNameList may return an error
*       if the target system is running under a shell other
*       than the Explorer shell.
*

# CtrlSetMultCurSel

The **CtrlSetMultCurSel** function searches the specified multi-selection list or combo box control. If `nSelectFlag` is set to `TRUE`, `CtrlSetMultCurSel` selects (highlights) the item when it is found. This function is for use only with custom dialogs.

## Syntax

```
CtrlSetMultCurSel (szDialogName, nControlID, szText, nSelectFlag);
```

## Parameters

**Table 123** ▪ CtrlSetMultCurSel Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a custom dialog.                                                                                                                                                                                                                                                                                                 |
| <b>nControlID</b>   | Specifies the resource ID of the multi-selection list box control in the dialog.                                                                                                                                                                                                                                                       |
| <b>szText</b>       | Specifies the search string.                                                                                                                                                                                                                                                                                                           |
| <b>nSelectFlag</b>  | <p>Indicates whether or not to select an item when CtrlSetMultCurSel finds it. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Indicates that the item is to be selected.</li> <li>• <b>FALSE</b>—Indicates that the item is not to be selected.</li> </ul> |

## Return Values

**Table 124** ▪ CtrlSetMultCurSel Return Values

| Return Value  | Description                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | CtrlSetMultCurSel successfully found the text in the control and either selected it or did not select it, as indicated in nSelectFlag. |
| <b>&lt; 0</b> | CtrlSetMultCurSel was unable to find the text in the control.                                                                          |

## CtrlSetMultCurSel Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlSetMultCurSel and CtrlGetMultCurSel
* functions.
*
```

```

* This script retrieves the names of all program folders
* on the target system and places them in a list. When the
* dialog is initialized, the CtrlSetList function sets this
* list to be displayed in the list box. The CtrlSetMultCurSel
* function is then called to select the user-selected
* folder.
*
* This list is then destroyed. A new list is created when the
* Next button is clicked. CtrlGetMultCurSel then retrieves the
* elements in the list box and assigns them to this new string
* list. This list is then displayed in an Sd dialog.
*
* Note: In order for this script to run properly, you must set
*       the RES_DIALOG_ID and RES_DIALOG_LISTBOX constants to a
*       dialog and list box created in _isuser.dll.
*
*       The GetGroupNameList function used in this example may
*       return an error if the target system is running under a
*       shell other than the Explorer shell.
*

```

# CtrlSetState

The **CtrlSetState** function sets the current state of a check box or option button control in a custom dialog. You can set certain characteristics of option buttons and check boxes when you create them using a resource or dialog editor. If you experience difficulties with the behavior of a button control, check the characteristics of the control in the editor.

## Syntax

```
CtrlSetState ( szDialogName, nControlID, nState );
```

## Parameters

**Table 125** ▪ CtrlSetState Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specifies the name of a dialog that contains the check box or option button control.                                                                                                                                                                                                                           |
| <b>nControlID</b>   | Specifies the resource ID of the check box or option button control.                                                                                                                                                                                                                                           |
| <b>nState</b>       | <p>Specifies the new state of the button control. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>BUTTON_CHECKED</b>—Sets the button's state to CHECKED.</li> <li>● <b>BUTTON_UNCHECKED</b>—Sets the button's state to UNCHECKED.</li> </ul> |

## Return Values

**Table 126** ▪ CtrlSetState Return Values

| Return Value  | Description                                                                        |
|---------------|------------------------------------------------------------------------------------|
| <b>0</b>      | CtrlSetState successfully set the state of the check box or option button control. |
| <b>&lt; 0</b> | CtrlSetState was unable to set the state of the control.                           |

## CtrlSetState Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlGetState and CtrlSetState functions.
*
* This example script displays a custom dialog that contains
* four check boxes. The script calls CtrlSetState to set the
* first two check boxes to checked. The last two are unchecked
* by default. When the end user clicks the Next button, the
* script calls CtrlGetState to retrieve the state of each
```

```

* each check box. The script then displays a message box that
* reports which check boxes were selected.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdAskOptions. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
\*-----*/

    MessageBox (szMsg, INFORMATION);
endif;

end;

```

## CtrlSetText

The **CtrlSetText** function sets the text of a single-line edit field, static text field, or button control in a custom dialog. To set the text in multi-line edit fields, call [CtrlSetMLEText](#).

### Syntax

```
CtrlSetText ( szDialogName, nControlID, szText );
```

## Parameters

**Table 127** ▪ CtrlSetText Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | Specify the name of the dialog that you want to modify.                                                                                                                                                                                                                                                                                  |
| <b>nControlID</b>   | Specify the resource ID of the single-line edit field, static text field, or button control in which text is to be set.                                                                                                                                                                                                                  |
| <b>szText</b>       | Specify the text to place in the control.<br><br> <p><b>Tip</b> ▪ If you want the control to be an HTML control, you can specify [html] at the beginning of the szText value. To learn more, see <a href="#">Using an HTML Control on a Dialog</a>.</p> |

## Return Values

**Table 128** ▪ CtrlSetText Return Values

| Return Value             | Description                                            |
|--------------------------|--------------------------------------------------------|
| <b>0</b>                 | CtrlSetText successfully set the text in the control.  |
| <b>ISERR_GEN_FAILURE</b> | CtrlSetText was unable to set the text in the control. |

## CtrlSetText Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the CtrlSetText, CtrlGetText, and CtrlSelectText
* functions.
*
* This example script displays a custom dialog with two
* edit boxes to obtain a user name and company name. The
* script calls CtrlSetText to place initial values into the
* edit boxes and CtrlSelectText to select the contents of the
* first edit box. When the user clicks the Next button, the
* script calls CtrlGetText to retrieve the contents of the edit
* boxes so that they can be displayed in a message box after
* the custom dialog is closed.
*
```

```

* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdRegisterUser. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
\*-----*/

// Dialog and control IDs.
#define RES_DIALOG_ID      12001 // ID of custom dialog
#define RES_PBUT_NEXT      1 // ID of Next button

```

# DefineDialog

The **DefineDialog** function defines a custom dialog. Call this function instead of [EzDefineDialog](#) when you need to specify a dialog attribute that cannot be specified with **EzDefineDialog**.

---

**Note** ▪ **DefineDialog** does not display the custom dialog. To display a custom dialog, you must call [WaitOnDialog](#).

## Syntax

```
DefineDialog ( szDialogName, hInstance, szDLLName, nDialogID, szDialogID, nReserved, hwndOwner,  
              lMsgLevel );
```

## Parameters

**Table 129** ▪ DefineDialog Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | <p>Specifies the name to associate with the dialog identified by szDialogID or nDialogID. To process this dialog, use this name in subsequent calls to custom dialog functions.</p> <p>Note that the dialog's name is case-sensitive; you must use it exactly as you have specified it in this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>hInstance</b>    | <p>Specifies the instance handle of the .dll file in which the dialog resides. If you specify the fully qualified name of the .dll file in szDLLName, you can specify 0 in this parameter. To obtain the instance handle of a .dll file, call the Microsoft Windows API <b>LoadLibrary</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szDLLName</b>    | <p>Specifies the name of the .dll file that contains the dialog resource. If this name is not qualified (that is, if you do not specify the drive and path with the file name), the InstallScript engine searches for the .dll file in the Windows folder. If it is not found there, the InstallScript engine searches the folders that are specified in the search path. When the dialog is located in _isuser.dll, you can specify a null string ("" ) in this parameter; the InstallScript engine automatically checks _isuser.dll if this parameter is specified as a null string ("" ).</p> <div data-bbox="782 1144 820 1188" data-label="Image"> </div> <p><b>Note</b> ▪ When you use a .dll file other than _isres.dll or _isuser.dll, you must call <a href="#">UseDLL</a> to load the .dll file before calling <b>DefineDialog</b>. To unload the .dll file from memory, call <a href="#">UnUseDLL</a> after calling <a href="#">ReleaseDialog</a>.</p> |
| <b>nDialogID</b>    | <p>Specifies the dialog's resource ID if you use a number rather than a string to identify the resource. This parameter is used only when szDialogID is a null string ("" ). It is recommended that you use nDialogID rather than szDialogID to identify the dialog resource.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 129** ■ DefineDialog Parameters (cont.)

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogID</b> | <p>Specifies the dialog's resource ID if you use a string rather than a number to identify the resource. If this parameter is a null string (""), nDialogID is used to identify the dialog resources. It is recommended that you use nDialogID rather than szDialogID to identify the dialog resource.</p> <p></p> <p><b>Note</b> ■ If you created the dialog in the Dialogs view, the dialog is created with a string ID; therefore, you must specify this name as the szDialogID parameter to define the dialog.</p> <p>If you override an existing dialog in the Dialogs view, the dialog has a numeric ID, and you must specify the ID in the nDialogID parameter.</p> <p>If you want to use numeric IDs in all cases—which is what is recommended—you must edit the dialog in the Dialogs view to change the ISResourceID property of the created dialog to the desired Dialog ID instead of 0. Note that if you do this, the dialog name is no longer used when the dialog is created; it is used only in the Dialogs view in InstallShield to identify the dialog. The dialog is built with the correct numeric ID.</p> |
| <b>nReserved</b>  | Pass zero in this parameter. No other value is allowed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>hwndOwner</b>  | Specifies the window handle of the owner window. Specify HWND_INSTALL in this parameter to make the main installation window the owner of the dialog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>IMsgLevel</b>  | <p>This parameter specifies which windows messages will be sent to the dialog. You must use the OR operator ( ) to combine one of the following constants with the constant DLG_CENTERED.</p> <ul style="list-style-type: none"> <li>● <b>DLG_MSG_STANDARD</b>—Filters out most Windows messages; only those directly related to the dialog's controls are passed to the dialog.</li> <li>● <b>DLG_MSG_ALL</b>—Passes most Windows messages.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Return Values

**Table 130** ▪ DefineDialog Return Values

| Return Value                       | Description                                                                                                                                                  |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                  | <b>DefineDialog</b> successfully defined the dialog.                                                                                                         |
| <b>DLG_ERR_ALREADY_EXISTS (-3)</b> | Indicates that you are trying to define a dialog that has already been defined in the installation script. You cannot define two dialogs with the same name. |
| <b>DLG_ERR (-1)</b>                | Indicates an unspecified error condition.                                                                                                                    |

## DefineDialog Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DefineDialog, EndDialog, and ReleaseDialog
* functions.
*
* This script opens a simple custom dialog that displays
* a bitmap. The dialog can be closed with any of three
* buttons: Back, Next, or Cancel.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdBitmap. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
* In order to use this dialog as a custom dialog, the
* script first defines it by calling DefineDialog. It then
* displays the dialog by calling WaitOnDialog. When an event
* ends dialog processing, EndDialog is called to close the
* dialog. Then the dialog is released from memory by
* a call to ReleaseDialog.
*
\*-----*/

// Dialog and control IDs.
#define RES_DIALOG_ID      12027 // ID of dialog itself
#define RES_PBUT_NEXT      1 // ID of Next button
#define RES_PBUT_CANCEL    9 // ID of Cancel button
#define RES_PBUT_BACK      12 // ID of Back button

```

```

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_DefinedDialog(HWND);

function ExFn_DefinedDialog(hMSI)
    STRING  szDialogName, szDLLName, szDialog;
    NUMBER  nDialog, nResult, nCmdValue;
    BOOL     bDone;
    HWND     hInstance, hwndParent, hwndDlg;
begin

    // Define the name of a dialog to pass as first
    // parameter to DefineDialog.
    szDialogName = "ExampleDialog";

    // DefineDialog's second parameter will be 0 because the
    // .dll file is in _isres.dll.
    hInstance = 0;

    // DefineDialog's third parameter will be null; installation will
    // search for the dialog in _isuser.dll and _isres.dll.
    szDLLName = "";

    // DefineDialog's fifth parameter will be null because the
    // dialog is identified by its ID in the fourth parameter.
    szDialog = "";

    // This value is reserved and must be 0.
    hwndParent = 0;

    // Define the dialog. The installation's main window will own the
    // dialog (indicated by HWND_INSTALL in parameter 7).
    nResult = DefineDialog (szDialogName, hInstance, szDLLName,
                           RES_DIALOG_ID, szDialog, hwndParent,
                           HWND_INSTALL, DLG_MSG_STANDARD|DLG_CENTERED);

    // Check for an error.
    if (nResult < 0) then
        MessageBox ("An error occurred while defining the dialog.", SEVERE);
        bDone = TRUE;
        abort;
    endif;

    // Initialize the indicator used to control the while loop.
    bDone = FALSE;

    // Loop until done.
    repeat

        // Display the dialog and return the next dialog event.
        nCmdValue = WaitOnDialog(szDialogName);

        // Respond to the event.
        switch (nCmdValue)

```

```

case DLG_CLOSE:
    // The user clicked the window's Close button.
    Do (EXIT);
case DLG_ERR:
    MessageBox ("Unable to display dialog. Setup canceled.", SEVERE);
    abort;
case DLG_INIT:
    // Initialize the back, next, and cancel button enable/disable states
    // for this dialog and replace %P, %VS, %VI with
    // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
    // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
    hwndDlg = CmdGetHwndDlg(szDialogName);
    SdGeneralInit(szDialogName, hwndDlg, 0, "");

case RES_PBUT_CANCEL:
    // The user clicked the Cancel button.
    Do (EXIT);
case RES_PBUT_NEXT:
    bDone = TRUE;
case RES_PBUT_BACK:
    bDone = TRUE;
    // check standard handling
    if (SdIsStdButton( nCmdValue ) && SdDoStdButton( nCmdValue )) then
        bDone = TRUE;
    endif;
endswitch;

until bDone;

// Close the dialog.
EndDialog (szDialogName);

// Free the dialog from memory.
ReleaseDialog (szDialogName);

end;

```

## DeinstallSetReference

The **DeinstallSetReference** function is obsolete.

If you want to check whether a file is locked during uninstallation, write script code that calls the **Is** function with the `FILE_LOCKED` constant for the `nlsFlag` parameter and that responds as needed.

### Syntax

```
DeinstallSetReference (szReferenceFile);
```

## DeinstallStart

The **DeinstallStart** function is obsolete. Installations create the required registry keys to enable uninstallation.

## Syntax

```
DeinstallStart (szObsolete, svObsolete, szObsolete, lReserved);
```

# Delay

The **Delay** function delays the execution of a script by a specified number of seconds. Other tasks running simultaneously with InstallShield proceed normally while InstallShield is delayed.

## Syntax

```
Delay ( nSeconds );
```

## Delay Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the Delay function.
 *
 * First, SdShowMsg is called to display a message box and Delay
 * is called to pause the script for three seconds. Then the
 * message box is removed and Delay is called again to pause for
 * two seconds. Finally, another message is displayed for three
 * seconds.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_Delay(HWND);

function ExFn_Delay(hMSI)
begin

    SdShowMsg ("This message will be displayed for three seconds.", TRUE);

    Delay (3);

    SdShowMsg ("", FALSE);

    Delay (2);

    SdShowMsg ("This is another message that will be displayed for a mere " +
        "three seconds.", TRUE);

    Delay (3);
```

```
end;
```

## DeleteCharArray

### Description

The **DeleteCharArray** function deletes the array of pointers to which pCharArray points.

### Syntax

```
DeleteCharArray ( pCharArray );
```

### Parameters

**Table 131** ▪ DeleteCharArray Parameters

| Parameter  | Description                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pCharArray | Specifies a pointer to an array of pointers to ANSI character strings. Typically, this pointer is returned by a previous call to <a href="#">GetCharArrayFromISStringArray</a> . |

### Return Values

**Table 132** ▪ DeleteCharArray Return Values

| Return Value  | Description                                 |
|---------------|---------------------------------------------|
| ISERR_SUCCESS | This function always returns ISERR_SUCCESS. |

## DeleteDir

The **DeleteDir** function deletes a subdirectory. Depending on the value you use in the parameter nFlag, you can delete a subdirectory only if it is empty, delete a subdirectory even if it contains files, or delete an entire root directory. Set nFlag with extreme caution.

**Note** ▪ Note the following restrictions:

- You cannot use DeleteDir to delete the current directory.
- You cannot delete files on a network system where you lack the appropriate rights.
- DeleteDir cannot delete read-only, hidden, or system files.
- If DeleteDir encounters a read-only file, the function can fail after having deleted only some of the files in the subdirectory.

## Syntax

```
DeleteDir( szDir, nFlag );
```

## Parameters

**Table 133** ▪ DeleteDir Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDir</b> | Specifies the fully qualified name of the directory to delete.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>nFlag</b> | <p>Specifies deletion options. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>ALLCONTENTS</b>—Deletes the directory in szDir, including all subdirectories and files beneath it. The directory you are deleting must be a subdirectory and cannot be a root directory of the drive.</li> <li>● <b>ONLYDIR</b>—Deletes the directory in szDir only if it is empty. Otherwise, the function fails.</li> <li>● <b>ROOT</b>—Deletes the directory in szDir even if it is the root directory. If szDir is a root directory, DeleteDir will delete everything on the disk.</li> </ul> |

## Return Values

**Table 134** ▪ DeleteDir Return Values

| Return Value  | Description                                                        |
|---------------|--------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully deleted the subdirectory. |
| <b>&lt; 0</b> | Indicates that the function was unable to delete the subdirectory. |

## DeleteDir Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the DeleteDir function.
 *
 * First, CreateDir is called to create a directory. Then,
 * DeleteDir is called to delete it.
 *
 \*-----*/

#define EXAMPLE_DIR "C:\\Newdir"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_DeleteDir(HWND);

function ExFn_DeleteDir(hMSI)
begin
    // Create a directory.
    if (CreateDir (EXAMPLE_DIR) != 0) then
        // Report the error; then terminate.
        MessageBox ("Unable to create directory.", SEVERE);
    else

        // Report success.
        MessageBox (EXAMPLE_DIR + " was created.", INFORMATION);

        // Delete the directory. If the directory is not
        // empty, it is not deleted.
        if (DeleteDir (EXAMPLE_DIR, ONLYDIR) = 0) then
            // Report success.
            MessageBox (EXAMPLE_DIR + " was deleted.", INFORMATION);
        else
            MessageBox ("Unable to delete directory.", SEVERE);
        endif;
    endif;

end;

```

## DeleteFile

The **DeleteFile** function deletes one or more files.

**Project** ▪ In a Basic MSI or InstallScript MSI project, this functionality might be better achieved by using the Windows Installer RemoveFiles action. For more information, see the [Windows Installer Help](#).

**Note** ▪ Note the following:

- You cannot use **DeleteFile** to delete files on a network system where you lack the appropriate rights.
- **DeleteFile** cannot delete read-only, hidden, or system files.
- You can use wild-card characters with **FindFile** to locate files and then delete them with **DeleteFile**.

## Syntax

```
DeleteFile ( szFile );
```

## Parameters

**Table 135** ▪ DeleteFile Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFile</b> | Specifies the names of the files to delete. If szFile specifies a fully qualified file name, that is, if it includes a path, <b>DeleteFile</b> will delete the file from specified directory. If szFile contains an unqualified file name, that is, without path information, <b>DeleteFile</b> deletes the file from the directory that is specified by the system variable TARGETDIR (in InstallScript installations) or INSTALLDIR (in Basic MSI and InstallScript MSI installations). You can include wildcard characters in szFile to delete more than one file. |

## Return Values

**Table 136** ▪ DeleteFile Return Values

| Return Value                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                                 | Indicates that the function successfully deleted the specified file or files.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ISERR_PATH_NOT_FOUND (0x80070003)</b> | The specified path was not found.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ISERR_FILE_NOT_FOUND (0x80070004)</b> | The specified file was not found or no files matched the specified wildcard.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>All other negative values</b>         | <p>Indicates that the function was unable to delete one or more of the specified files. In the case of multiple files, only the error for the last file that could not be deleted is returned. The system variable <b>ERRORFILENAME</b> contains a semicolon delimited list of the files that could not be deleted.</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <b>FormatMessage</b>.</p> |

## DeleteFile Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DeleteFile function.
*
```

```

* First, DeleteFile is called to delete a specified file from a
* directory. Then it is called again to delete all files with
* the extension "sys" from the same directory.
*
* Note: Before running this script, create a directory named
*       ISExmpl in the root of drive C. Then create a file
*       named ISExmpl.txt in that directory. Finally, create
*       two or more files with the extension "sys" in that
*       directory. These files will be deleted by the script.
*
\*-----*/

#define DEL_DIR      "C:\\ISExmpl"
#define DEL_FILE     "ISExmpl.txt"
#define DEL_SYS_FILES "*.sys"
#define TITLE_TEXT  "DeleteFile example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_DeleteFile(HWND);

function ExFn_DeleteFile(hMSI)
    STRING szMsg;
begin

    // Delete the file specified by DEL_FILE from the target directory.
    if (DeleteFile (DEL_DIR ^ DEL_FILE) < 0) then
        MessageBox ("First call to DeleteFile failed.", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE_TEXT, "%s was delete from %s.",
                    DEL_FILE, DEL_DIR);
    endif;

    // Delete the files specified by DEL_SYS_FILES
    // from the target directory.
    if (DeleteFile (DEL_SYS_FILES) < 0) then
        MessageBox ("Second call to DeleteFile failed.", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE_TEXT,
                    "All files matching %s were delete from %s.",
                    DEL_SYS_FILES, DEL_DIR);
    endif;

end;

```

## DeleteFolderIcon

The [DeleteShortcut](#) function supersedes the **DeleteFolderIcon** function.

The **DeleteFolderIcon** function removes a shortcut from a folder.

---

**Note** - *DeleteFolderIcon cannot be used for Internet shortcuts.*

## Syntax

```
DeleteFolderIcon ( szProgramFolder, szItemName );
```

## Parameters

**Table 137** ▪ DeleteFolderIcon Parameters

| Parameter              | Description                                                            |
|------------------------|------------------------------------------------------------------------|
| <b>szProgramFolder</b> | Specifies the name of the folder that contains the shortcut to remove. |
| <b>szItemName</b>      | Specifies the name of the shortcut to delete.                          |

## Return Values

**Table 138** ▪ DeleteFolderIcon Parameters

| Return Value  | Description                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully deleted the specified shortcut.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |
| <b>&lt; 0</b> | Indicates that the function was unable to delete the shortcut.                                                                                                                                                                                       |

## DeleteFolderIcon Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DeleteFolderIcon and DeleteProgramFolder
* functions.
*
* This script deletes the 'Notepad Example' icon from the
* 'Example folder' folder. DeleteProgramFolder is then
* called again to delete this folder.
*
* Note: In order for this script to run properly, you must set
* the preprocessor constants to a valid folder and icon
* on the target system. To easily create this example
* folder and icon, run the AddFolderIcon example #3.
*
\*-----*/
```

```

#define FOLDER "C:\\Windows\\Example folder"
#define ICON   "Notepad Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_DeleteFolderIcon(HWND);

function ExFn_DeleteFolderIcon(hMSI)
begin

    // Display the folder.
    ShowProgramFolder (FOLDER, SW_SHOW);
    Delay (3);

    // Delete the 'Notepad Example' icon.
    if (DeleteFolderIcon (FOLDER, ICON) < 0) then
        MessageBox ("DeleteFolderIcon failed.", SEVERE);
    endif;

    // Delete the 'Example folder' icon.
    if (DeleteProgramFolder (FOLDER) < 0) then
        MessageBox ("DeleteProgramFolder failed.", SEVERE);
    endif;

end;

```

## DeleteProgramFolder

The **DeleteShortcutFolder** function supersedes the **DeleteProgramFolder** function.

The **DeleteProgramFolder** function deletes a program folder (that is, a subfolder of the Start menu's Programs folder) and its contents, including all shortcuts and all of the program folder's subfolders and their contents. DeleteProgramFolder cannot delete the Programs folder.

**Tip** ▪ In a Windows Installer based or InstallScript MSI project, this functionality is possibly better achieved by using the Windows Installer RemoveFolders action. Or, if you are simply uninstalling, the MSI engine handles the removal of all files and folders created during the setup. For more information on the RemoveFolders action, see the [Windows Installer Help](#).

### Syntax

```
DeleteProgramFolder ( szFolderName );
```

## Parameters

**Table 139** ▪ DeleteProgramFolder Parameters

| Parameter           | Description                                 |
|---------------------|---------------------------------------------|
| <b>szFolderName</b> | Specifies the name of the folder to remove. |

## Return Values

**Table 140** ▪ DeleteProgramFolder Return Values

| Return Value  | Description                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully removed the specified folder.                                                                                                                                                                   |
| <b>&lt; 0</b> | Indicates that the function was unable to remove the folder.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## DeleteProgramFolder Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DeleteFolderIcon and DeleteProgramFolder
* functions.
*
* This script deletes the 'Notepad Example' icon from the
* 'Example folder' folder. DeleteProgramFolder is then
* called again to delete this folder.
*
* Note: In order for this script to run properly, you must set
*       the preprocessor constants to a valid folder and icon
*       on the target system. To easily create this example
*       folder and icon, run the AddFolderIcon example #3.
*
\*-----*/

#define FOLDER "C:\\Windows\\Example folder"
#define ICON   "Notepad Example"
```

```
// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_DeleteProgramFolder(HWND);

function ExFn_DeleteProgramFolder(hMSI)
begin

    // Display the folder.
    ShowProgramFolder (FOLDER, SW_SHOW);
    Delay (3);

    // Delete the 'Notepad Example' icon.
    if (DeleteFolderIcon (FOLDER, ICON) < 0) then
        MessageBox ("DeleteFolderIcon failed.", SEVERE);
    endif;

    // Delete the 'Example folder' icon.
    if (DeleteProgramFolder (FOLDER) < 0) then
        MessageBox ("DeleteProgramFolder failed.", SEVERE);
    endif;

end;
```

## DeleteShortcut

The **DeleteShortcut** function removes a shortcut from a folder.

---

**Note** • **DeleteShortcut** cannot be used for Internet shortcuts.

### Syntax

```
DeleteShortcut (szShortcutFolder, szName);
```

## Parameters

**Table 141** ▪ DeleteShortcut Parameters

| Parameter               | Description                                                                        |
|-------------------------|------------------------------------------------------------------------------------|
| <b>szShortcutFolder</b> | Specify the name of the folder that contains the shortcut that you want to remove. |
| <b>szName</b>           | Specify the name of the shortcut that you want to remove.                          |

## Return Values

**Table 142** ▪ DeleteShortcut Parameters

| Return Value  | Description                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully deleted the specified shortcut.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |
| <b>&lt; 0</b> | Indicates that the function was unable to delete the shortcut.                                                                                                                                                                                       |

## DeleteShortcut Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DeleteShortcut and DeleteShortcutFolder
* functions.
*
* This script deletes the Notepad Example 3 shortcut from the
* Example folder 3 folder. DeleteShortcutFolder is then
* called again to delete this folder.
*
* Note: In order for this script to run properly, you must set
*       the preprocessor constants to a valid folder and shortcut
*       on the target system. To easily create this example
*       folder and shortcut, run the CreateShortcut example 3.
*
\*-----*/

#define FOLDER "C:\\Windows\\Example folder 3"
#define SHORTCUT "Notepad Example 3"
```

```

function OnFirstUIAfter()
begin

    // Display the folder.
    ShowProgramFolder (FOLDER, SW_SHOW);
    Delay (3);

    // Delete the Notepad Example 3 shortcut.
    if (DeleteShortcut (FOLDER, SHORTCUT) < 0) then
        MessageBox ("DeleteShortcut failed.", SEVERE);
    endif;

    // Delete the Example folder 3 shortcut.
    if (DeleteShortcutFolder (FOLDER) < 0) then
        MessageBox ("DeleteShortcutFolder failed.", SEVERE);
    endif;

end;

```

## DeleteShortcutFolder

The **DeleteShortcutFolder** function removes a shortcut folder (that is, a subfolder of the Start menu's Programs folder) and its contents, including all shortcuts and all of the shortcut folder's subfolders and their contents.

**DeleteShortcutFolder** cannot remove the Programs folder.

**Tip** ▪ In a Basic MSI or InstallScript MSI project, this functionality is possibly better achieved by using the Windows Installer RemoveFolders action. Or, if you are simply uninstalling, the Windows Installer engine handles the removal of all files and folders that were created during the installation. For more information on the RemoveFolders action, see the [Windows Installer Help](#).

### Syntax

```
DeleteShortcutFolder ( szFolderName );
```

## Parameters

**Table 143** ▪ DeleteShortcutFolder Parameters

| Parameter           | Description                               |
|---------------------|-------------------------------------------|
| <b>szFolderName</b> | Specify the name of the folder to remove. |

## Return Values

**Table 144** ▪ DeleteShortcutFolder Return Values

| Return Value  | Description                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully removed the specified folder.                                                                                                                                                                   |
| <b>&lt; 0</b> | Indicates that the function was unable to remove the folder.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## DeleteShortcutFolder Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DeleteShortcut and DeleteShortcutFolder
* functions.
*
* This script deletes the Notepad Example 3 shortcut from the
* Example folder 3 folder. DeleteShortcutFolder is then
* called again to delete this folder.
*
* Note: In order for this script to run properly, you must set
*       the preprocessor constants to a valid folder and shortcut
*       on the target system. To easily create this example
*       folder and shortcut, run the CreateShortcut example 3.
*
\*-----*/

#define FOLDER "C:\\Windows\\Example folder 3"
#define SHORTCUT "Notepad Example 3"

function OnFirstUIAfter()

```

```

begin

    // Display the folder.
    ShowProgramFolder (FOLDER, SW_SHOW);
    Delay (3);

    // Delete the Notepad Example 3 shortcut.
    if (DeleteShortcut (FOLDER, SHORTCUT) < 0) then
        MessageBox ("DeleteShortcut failed.", SEVERE);
    endif;

    // Delete the Example folder 3 shortcut.
    if (DeleteShortcutFolder (FOLDER) < 0) then
        MessageBox ("DeleteShortcutFolder failed.", SEVERE);
    endif;

end;

```

## DeleteWCharArray

### Description

The **DeleteWCharArray** function deletes the array of pointers to which pCharArray points.

### Syntax

```
DeleteWCharArray ( pCharArray );
```

## Parameters

**Table 145** ▪ DeleteWCharArray Parameters

| Parameter         | Description                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>pCharArray</b> | Specifies a pointer to an array of pointers to Unicode character strings. Typically, this pointer is returned by a previous call to <a href="#">GetWCharArrayFromISStringArray</a> . |

## Return Values

**Table 146** ▪ DeleteWCharArray Return Values

| Return Value         | Description                                 |
|----------------------|---------------------------------------------|
| <b>ISERR_SUCCESS</b> | This function always returns ISERR_SUCCESS. |

# DialogSetFont

The **DialogSetFont** function sets the font for InstallScript dialogs that are displayed at run time. This function affects built-in InstallScript dialogs and custom InstallScript dialogs (that is, dialogs that are defined through [EzDefineDialog](#) or [DefineDialog](#)). This function does not affect dialogs that are displayed by calling the Windows API function `MessageBox`, which are displayed in the font specified by the user for message boxes (specified using the Windows Control panel). This function does not affect the text in the title bar of any dialog; the font of dialog title bars is set by Windows.

## Syntax

```
DialogSetFont (szFontName, nFontSize, nReserved);
```

## Parameters

**Table 147** ▪ DialogSetFont Parameters

| Parameter         | Description                                                   |
|-------------------|---------------------------------------------------------------|
| <b>szFontName</b> | Specifies the font to be used—for example, “Times New Roman”. |
| <b>nFontSize</b>  | Specifies the font size—for example, 10.                      |
| <b>nReserved</b>  | Pass 0 (zero) in this parameter. No other value is allowed.   |

## Return Values

DialogSetFont always returns 0 (zero). If the function cannot change the font, dialog text is displayed in the system font.

## Additional Information

When changing the font of InstallShield dialogs, use a font that you know is available on any system that the setup is running on. Also, be sure to test the setup on a variety of screen resolutions to ensure that the font works correctly.

# DialogSetInfo

**Edition** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI (in event-driven InstallScript—not in InstallScript custom actions)*

The **DialogSetInfo** function changes the following display elements in run-time dialogs:

- The image to be displayed
- The style of the check boxes used to obtain end-user selections
- The precision of the values that indicate available hard drive space

You must call **DialogSetInfo** each time that you want to change a particular aspect of a single dialog. Changes that are made by a call to **DialogSetInfo** remain in effect for the remainder of the installation or until they are changed again by a subsequent call to **DialogSetInfo**.

**Note** ▪ If your script calls **DialogSetInfo** before calling any of the Sd dialog functions, the call to **DialogSetInfo** must be preceded by a call to *SdInit*. If it is not, the call to **DialogSetInfo** has no effect.

## Syntax

```
DialogSetInfo ( nInfoType, szInfoString, nParameter );
```

## Parameters

**Table 148** • DialogSetInfo Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nInfoType</b> | <p>Specifies the display feature to be modified. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li> <b>DLG_INFO_USEDECIMAL</b>—By default, the values displayed to indicate feature sizes, available disk space, and required disk space are rounded to the nearest kilobyte or megabyte. Pass this constant when you want these values displayed to the nearest tenth of a kilobyte or megabyte. The following dialogs are affected by this parameter: <b>FeatureDialog</b>, <b>SdFeatureDialog</b>, <b>SdFeatureDialog2</b>, <b>SdFeatureDialogAdv</b>, and <b>SdFeatureMult</b>. </li> <li> <b>DLG_INFO_KUNITS</b>—By default, the values displayed to indicate feature sizes, available disk space, and required disk space are displayed as a measurement in megabytes. Pass this constant to display these measurements in kilobytes. The following dialogs are affected by this parameter: <b>FeatureDialog</b>, <b>SdFeatureDialog</b>, <b>SdFeatureDialog2</b>, <b>SdFeatureDialogAdv</b>, and <b>SdFeatureMult</b>. </li> <li> <b>DLG_INFO_ALTIMAGE</b>—Specifies an alternate bitmap to be displayed in the dialog. If <b>nParameter</b> is set to <b>DLG_INFO_ALTIMAGE_VERIFY_BMP</b> or <b>TRUE</b>, <b>szInfoString</b> should specify the image to be displayed in the dialog. This parameter applies to all dialogs that display the standard installation image on the left side of the dialog. For more information, see the <b>nParameter</b> description. <p>Display effects that have been set with <b>SetDisplayEffect</b> do not apply to alternate images, which are always displayed without any special effects.</p> </li> <li> <b>DLG_INFO_ALTIMAGE_HIDPI</b>—Specifies a high DPI image to be displayed in the dialog. High DPI image types supported include BMP, GIF, JPEG, PNG, and TIFF. For best results, in order to ensure the image is centered and shifted to the right of the header, use images with an aspect ratio of 2.5:1, similar to the images shipped with InstallShield (where the actual logo portion of the image is approximately half of the image width and the other half is transparent), and note the following image sizing recommendations: <ul style="list-style-type: none"> <li>For a 100% scaled image, your image should be 180x75</li> <li>For a 200% scaled image, your image should be 360x150</li> <li>For a 250% scaled image, your image should be 450x187, etc.</li> </ul> <p>If transparency is required, image types that support transparency (such as PNG) should be used and <b>szInfoString</b> should specify the name of the image to be displayed (optionally including the path) in the dialog. This parameter applies to all dialogs that display the standard installation image on the left side of the dialog. When <b>DLG_INFO_ALTIMAGE_HIDPI</b> is passed in <b>nInfoType</b>, the following parameter values are expected: <b>szInfoString</b> and <b>nParameter</b>. For more information, see the <b>szInfoString</b> and <b>nParameter</b> descriptions.</p> <p>Display effects that have been set with <b>SetDisplayEffect</b> do not apply to alternate images, which are always displayed without any special effects.</p> </li> </ul> |

**Table 148** ▪ DialogSetInfo Parameters (cont.)

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szInfoString</b> | <p>When DLG_INFO_ALTIMAGE is passed in nInfoType, this parameter specifies the file name of an alternate bitmap to display and, optionally, a set of bitmap attributes. If bitmap attributes are included, the string passed in this parameter should be formatted as follows:</p> <p>"bitmap file name;transparent flag;3-D flag;&lt;unused&gt;;background color"</p> <ul style="list-style-type: none"> <li>● <b>Bitmap file name</b>—Specifies the name of the bitmap file. If the file name is unqualified (that is, if it does not include a drive designation and path), the installation searches for the bitmap in <b>SUPPORTDIR</b>.</li> <li>● <b>Transparent flag</b>—Indicates whether to display the bitmap transparently. When this flag is 1 (true), all portions of the bitmap that are magenta (RGB Value: 255,0,255) will be displayed transparently. The default for this parameter is 0 (non-transparent).</li> <li>● <b>3-D flag</b>—Indicates whether to add a 3-D border around the edges of the static field that contains the bitmap. The default for this parameter is 0 (no 3D border).</li> <li>● <b>&lt;unused&gt;</b>—This portion of the formatted string is ignored, but it must be included. That is, the formatted string must contain four semicolons, with two semicolons between the 3-D flag and the background color.</li> <li>● <b>Background color</b>—Indicates the color to use for the background of the static text field. Note that this color will be visible only if the bitmap is smaller than the static text field in which it appears or if the transparent flag is set to 1 and the bitmap has transparent areas. The background color must be expressed as an RGB value, that is, as three numeric values separated by commas.</li> </ul> <p>The following example will display the bitmap from the file MyBitmap.bmp, which is located in the SUPPORTDIR folder. The bitmap is placed on a black background and has a three-dimensional border. Any parts of the bitmap that are magenta are displayed in the background color of black.</p> <pre>SUPPORTDIR ^ "MyBitmap.bmp" + ";1;1;;0,0,0"</pre> <p>Note that the standard bitmap measures 57 x 53. An alternate bitmap should be about this size as well. If the bitmap is larger than this size, it will be centered vertically within the title area, and the right side of the bitmap will be aligned with the right side of the dialog. (In the Welcome, SdWelcome, and SdFinish dialogs, the right side of the bitmap will be aligned with the right side of the larger image within which the bitmap appears.) The left side of the bitmap will extend as far to the left of the dialog as necessary. Any part of the bitmap that extends below the title area of the dialog will be clipped. If the bitmap is smaller than 57 x 53 it will be will displayed correctly, but it will not be resized or extended.</p> <p>When DLG_INFO_ALTIMAGE_HIDPI is passed in nInfoType, this parameter specifies the file name of a high DPI image to display, optionally including the path. If no path to the file is specific, the file is assumed to be in SUPPORTDIR. If this file does not exist, DialogSetInfo returns ISERR_FILE_NOT_FOUND.</p> <p>This parameter is ignored when the default image is being restored or when nInfoType is not DLG_INFO_ALTIMAGE or DLG_INFO_ALTIMAGE_HIDPI.</p> |

**Table 148** ▪ DialogSetInfo Parameters (cont.)

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nParameter</b> | <p>Operates in conjunction with nInfoType to specify dialog features.</p> <p>When nInfoType is DLG_INFO_ALTIMAGE, pass one of the following predefined constants to specify which bitmap to display:</p> <ul style="list-style-type: none"> <li>• <b>DLG_INFO_ALTIMAGE_VERIFY_BITMAP</b>—Specifies that the bitmap that is indicated by szInfoString should be used in subsequent dialogs. Before this bitmap is used, the installation checks for the existence of the bitmap.</li> <li>• <b>DLG_INFO_ALTIMAGE_REVERT_IMAGE (-1)</b>—Specifies that subsequent dialogs should display the default bitmap. The installation does not check for the existence of a bitmap.</li> <li>• <b>TRUE</b>—Specifies that the bitmap that is indicated by szInfoString should be used in subsequent dialogs. The installation does not check for the existence of the bitmap.</li> </ul> <p>When nInfoType is DLG_INFO_ALTIMAGE_HIDPI, nParameter specifies the DPI scaling percentage. For example, pass 200 for a 200% image scale, 150 for a 150% scale, etc. The minimum supported scaling value is 25. If 0 is passed for this value, no image is displayed. If DLG_INFO_ALTIMAGE_REVERT_IMAGE is passed, the previous image used is displayed.</p> <p>When nInfoType is either DLG_INFO_KUNITS or DLG_INFO_USEDECIMAL, pass one of the following predefined constants to specify how sizes should be displayed:</p> <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Specifies that sizes should be displayed as indicated by nInfoType.</li> <li>• <b>FALSE</b>—Specifies that sizes should be displayed in the default style.</li> </ul> |

## Return Values

**Table 149** ▪ DialogSetInfo Return Values

| Return Value                             | Description                                                                                                                                                                 |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS (0)</b>                 | The function successfully set the specified style. If DLG_INFO_ALTIMAGE_VERIFY_BITMAP was passed in nParameter, this return value also indicates that the bitmap was found. |
| <b>&lt; ISERR_SUCCESS (&lt; 0)</b>       | An unspecified error occurred when the function attempted to set the dialog information.                                                                                    |
| <b>ISERR_FILE_NOT_FOUND (0x80070004)</b> | The image that was indicated by szInfoString was not found.                                                                                                                 |

## Additional Information

To preview the effects of a call to **DialogSetInfo** in an InstallScript installation, run the Dialog Sampler (which is available from the Tools menu's InstallScript submenu), change the attributes of the dialogs (by clicking the Attributes button), then examine the changes in dialogs such as **SdFeatureMult**.

## DialogSetInfo Example

**Edition** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI (in event-driven InstallScript—not in InstallScript custom actions)*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the DialogSetInfo function.
 *
 * This script calls AskText twice. On the first call the
 * AskText dialog displays the default bitmap. Then
 * DialogSetInfo is called to specify an alternate bitmap;
 * that bitmap is then displayed on the second call to AskText.
 *
 * Note: Before running this script, set the defined constant
 *       FULL_BMP_PATH so that it references a bitmap file
 *       included in the Support Files/Billboards view.
 *
\*-----*/

#define FULL_BMP_PATH SUPPORTDIR ^ "MyBitmap.bmp"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

function OnBegin()
    STRING  szText, szMsg, szBmpPath;
    STRING  svReturnText;
    NUMBER  nReturn;
begin

start:

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Display the AskText dialog with its default bitmap.
    szText  = "Default Bitmap.";
    szMsg    = "The bitmap on the left is the default.";
    nReturn = AskText (szMsg, szText, svReturnText);

    // Enable the Back button.
    Enable (BACKBUTTON);

    szBmpPath = FULL_BMP_PATH;

    // Set the alternate bitmap for the AskText dialog.
    DialogSetInfo (DLG_INFO_ALTIMAGE, szBmpPath, TRUE);

    // Set the text for display in the AskText dialog.
```

```

szText = "Alternate Bitmap.";
szMsg  = "The bitmap on the left is a custom bitmap. This alternate " +
        "bitmap was displayed using the DLG_INFO_ALTBITMAP option in " +
        "DialogSetInfo.";

// Display the AskText dialog with the alternate
// bitmap.
nReturn = AskText (szMsg, szText, svReturnText);

// Handle Back button.
if (nReturn = BACK) then
    // Restore the default bitmap setting.
    DialogSetInfo (DLG_INFO_ALTIMAGE, "", DLG_INFO_ALTIMAGE_REVERT_IMAGE);
    goto start;
endif;

end;

```

## Dialog Styles

Four different dialog styles are available:

- [CHECKBOX Dialog Style](#)
- [CHECKBOX95 Dialog Style](#)
- [CHECKMARK Dialog Style](#)
- [CHECKLINE Dialog Style](#)

## CHECKBOX Dialog Style

**Figure 1:** CHECKBOX Dialog Style

## CHECKBOX95 Dialog Style

**Figure 2:** CHECKBOX95 Dialog Style

## CHECKMARK Dialog Style

**Figure 3:** CHECKMARK Dialog Style

## CHECKLINE Dialog Style

## DIFxDriverPackageGetPath

**Project** - This function applies to InstallScript projects only. This function is not required in InstallScript MSI projects since DIFx can be called by the Windows Installer in those projects.

The **DIFxDriverPackageGetPath** function retrieves the fully qualified path to a driver store .inf file.

**Note** - This function calls the DIFxAPI function *DriverPackageGetPath*. See the DIFxAPI documentation for additional details regarding this function and its parameters and return values.

### Syntax

```
DIFxDriverPackageGetPath( byval string szDriverPackageInfPath, byref string svDestInfPath, byval number nISFlags );
```

## Parameters

**Table 150** ▪ DIFxDriverPackageGetPath Parameters

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDriverPackageInfPath</b> | Specifies the fully qualified path to a driver package .inf file for which to retrieve the corresponding driver store .inf file.                                                                                                                                                                                                                                                  |
| <b>svDestInfPath</b>          | Specifies the fully qualified path of the driver store .inf file that corresponds to the driver package .inf file supplied by DriverPackageInfPath.                                                                                                                                                                                                                               |
| <b>nISFlags</b>               | Specifies InstallScript-specific flags. The following flags are available: <ul style="list-style-type: none"> <li>● <b>0</b>—Default behavior</li> <li>● <b>ISDIFX_OPTION_DONT_RESOLVE_TEXTSUBS</b>—By default, the function resolves any text substitutions found in szDriverPackageInfPath. However, if this flag is specified, text substitutions are not resolved.</li> </ul> |

## Return Values

**Table 151** ▪ DIFxDriverPackageGetPath Return Values

| Return Value              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | The function was successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>&lt; ISERR_SUCCESS</b> | <p>The function failed.</p> <p>If the return value from <b>DriverPackageGetPath</b> is a Win32 error (a positive return value), ISERR_WIN_BASE is added to the error to ensure that it is &lt; ISERR_SUCCESS.</p> <p>You can use the following code to get the original Win32 error, if desired:</p> <pre>if( nResult &amp; ISERR_WIN_BASE ) then nResult = nResult - ISERR_WIN_BASE; endif;</pre> <p>For a list of specific errors, see DIFxAPI Errors (InstallScript Projects).</p> |

## Additional Information

For more information on DIFx and DIFxAPI, see the [MSDN Library](#).

# DIFxDriverPackageInstall

**Project** ▪ This function applies to InstallScript projects only. This function is not required in InstallScript MSI projects since DIFx can be called by the Windows Installer in those projects.

The **DIFxDriverPackageInstall** function installs a driver package in the driver store and then installs the driver in the system. If all of the files associated with the driver are in a single component or you can guarantee that all appropriate driver files will be installed when this component's Installed event is called, then the recommended place for calling this function is in the component containing the DIFx driver's Installed event. Otherwise, call this function in the installation's OnMoved event.

If uninstall logging is enabled when this function is called, the driver installed by this function is logged for uninstallation and is automatically removed by the OnUninstallingDIFxDriverFile event when the application is removed.

---

**Note** ▪ This function calls the DIFxAPI function *DriverPackageInstall*. See the *DIFxAPI* documentation for additional details regarding this function and its parameters and return values.

## Syntax

```
DIFxDriverPackageInstall( byval string szDriverPackageInfPath, byval number nFlags, byval number  
    nISFlags );
```

## Parameters

**Table 152** ▪ DIFxDriverPackageInstall Parameters

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDriverPackageInfPath</b> | String that supplies the fully qualified path to the driver package .inf file of the driver package to install.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>nFlags</b>                 | <p>One or more flags that control the installation operation. In most cases you can specify 0 because the installer will automatically add the appropriate flags.</p> <p>The following additional flags can be specified manually:</p> <div data-bbox="596 630 633 674" data-label="Image"> </div> <p><b>Note</b> ▪ These flags are defined by and passed directly to the <i>Flags</i> parameter of the DIFxAPI function <i>DriverPackageInstall</i>. See the DIFxAPI documentation for additional information regarding these flags.</p> <ul style="list-style-type: none"> <li>● <b>DRIVER_PACKAGE_REPAIR</b>—Re-installs the specified driver package in the driver store even if the driver package is already installed. This flag is specified automatically in repair mode.</li> <li>● <b>DRIVER_PACKAGE_ONLY_IF_DEVICE_PRESENT</b>—(Applies only to PnP function drivers) Preinstalls and installs the driver only if the driver package is a better match to a device in the device tree.</li> <li>● <b>DRIVER_PACKAGE_FORCE</b>—(Applies only to PnP function drivers) By default, installs a new driver for device only if the new driver is a better match for the device than the driver currently installed for the device. If you specify this flag, the function preinstalls and installs the specified driver package even if the driver package currently installed for a device is a better match for the device than the specified driver package.</li> <li>● <b>DRIVER_PACKAGE_SILENT</b>—Suppresses the display of user dialogs. If a user interaction is required to continue the installation, for example, in response to a driver signing dialog, the installation operation fails without displaying a user message. The function returns an error code that indicates the cause of the failure.</li> <li>● <b>DRIVER_PACKAGE_LEGACY_MODE</b>—Preinstalls and installs unsigned driver packages and driver packages that cannot be completely preinstalled because there are files that cannot be found.</li> </ul> |

**Table 152** ▪ DIFxDriverPackageInstall Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nISFlags</b> | <p>Specifies InstallScript-specific flags. The following flags are available:</p> <ul style="list-style-type: none"> <li>● <b>0</b>—Default behavior</li> <li>● <b>ISDIFX_OPTION_DONT_ASSOCIATE</b>—By default, associates the installed driver with the application being installed. If this flag is specified the driver is not associated with any application.</li> <li>● <b>ISDIFX_OPTION_NO_REPAIR</b>—By default, the function automatically adds the DRIVER_PACKAGE_REPAIR flag when calling the <b>DriverPackagePreinstall</b> function if REINSTALLMODE is TRUE. If this flag is specified, DRIVER_PACKAGE_REPAIR is not added automatically. However, it is passed if it is specified in nFlags.</li> <li>● <b>ISDIFX_OPTION_LOG_IN_DRIVER_PACKAGE_PATH</b>—By default, the function logs the installed driver for uninstallation in the installed driver cache. If this flag is specified, the driver is logged in the package path instead.</li> <li>● <b>ISDIFX_OPTION_DONT_RESOLVE_TEXTSUBS</b>—By default, the function resolves any text substitutions found in szDriverPackageInfPath. However, if this flag is specified, text substitutions are not resolved.</li> </ul> |

## Return Values

**Table 153** ▪ DIFxDriverPackageInstall Return Values

| Return Value              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | The function was successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>&lt; ISERR_SUCCESS</b> | <p>The function failed.</p> <p>If the return value from <b>DriverPackageInstall</b> is a Win32 error (a positive return value), ISERR_WIN_BASE is added to the error to ensure that it is &lt; ISERR_SUCCESS.</p> <p>You can use the following code to get the original Win32 error, if desired:</p> <pre>if( nResult &amp; ISERR_WIN_BASE ) then nResult = nResult - ISERR_WIN_BASE; endif;</pre> <p>For a list of specific errors, see DIFxAPI Errors (InstallScript Projects).</p> |

## Additional Information

- For more information on DIFx and DIFxAPI, see the [MSDN Library](#).
- When a driver is installed by **DIFxDriverPackageInstall** or uninstalled by **DIFxDriverPackageUninstall**, the driver is associated with the application being installed by the installation by default. This association can be disabled by specifying ISDIFX\_OPTION\_DONT\_ASSOCIATE. These functions use the following script variables to determine the application to associate:

- `ISDIFXAPPID`
- `IFX_PRODUCT_DISPLAY_NAME`
- `IFX_PRODUCT_NAME`
- `IFX_COMPANY_NAME`

## DIFxDriverPackagePreinstall

**Project** ▪ This function applies to InstallScript projects only. This function is not required in InstallScript MSI projects since DIFx can be called by the Windows Installer in those projects.

The **DIFxDriverPackagePreinstall** function preinstalls a driver package for a Plug and Play (PnP) function driver in the driver store and installs the .inf file for the driver package in the system .inf file directory. If all of the files associated with the driver are in a single component or you can guarantee that all appropriate driver files will be installed when this component's Installed event is called, then the recommended place for calling this function is in the component containing the DIFx driver's Installed event. Otherwise, call this function in the installation's OnMoved event.

If uninstall logging is enabled when this function is called, the driver pre-installed by this function is logged for uninstallation and is automatically removed by the OnUninstallingDIFxDriverFile event when the application is removed.

**Note** ▪ This function calls the DIFxAPI function *DriverPackagePreinstall*. See the DIFxAPI documentation for additional details regarding this function and its parameters and return values.

### Syntax

```
DIFxDriverPackagePreinstall( byval string szDriverPackageInfPath, byval number nFlags, byval number nISFlags );
```

## Parameters

**Table 154** ▪ DIFxDriverPackagePreinstall Parameters

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDriverPackageInfPath</b> | String that supplies the fully qualified path to the driver package .inf file of the driver package to pre-install.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>nFlags</b>                 | <p>One or more flags that control the installation operation. In most cases, specify 0 to have the installer automatically add the appropriate flags.</p> <p>The following additional flags can be specified manually:</p> <div data-bbox="630 630 669 674" data-label="Image"> </div> <p><b>Note</b> ▪ These flags are defined by and passed directly to the <i>Flags</i> parameter of the DIFxAPI function <i>DriverPackagePreinstall</i>. See the DIFxAPI documentation for additional information regarding these flags.</p> <ul style="list-style-type: none"> <li>• <b>DRIVER_PACKAGE_REPAIR</b>—Re-installs the specified driver package in the driver store even if the driver package is already installed. This flag is specified automatically in repair mode.</li> <li>• <b>DRIVER_PACKAGE_ONLY_IF_DEVICE_PRESENT</b>—(Applies only to PnP function drivers) Preinstalls and installs the driver only if the driver package is a better match to a device in the device tree.</li> <li>• <b>DRIVER_PACKAGE_FORCE</b>—(Applies only to PnP function drivers) By default, installs a new driver for device only if the new driver is a better match for the device than the driver currently installed for the device. If you specify this flag, the function preinstalls and installs the specified driver package even if the driver package currently installed for a device is a better match for the device than the specified driver package.</li> <li>• <b>DRIVER_PACKAGE_SILENT</b>—Suppresses the display of user dialogs. If a user interaction is required to continue the installation, for example, in response to a driver signing dialog, the installation operation fails without displaying a user message. The function returns an error code that indicates the cause of the failure.</li> <li>• <b>DRIVER_PACKAGE_LEGACY_MODE</b>—Preinstalls and installs unsigned driver packages and driver packages that cannot be completely preinstalled because there are files that cannot be found.</li> </ul> |

**Table 154** ▪ DIFxDriverPackagePreinstall Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nISFlags</b> | <p>Specifies InstallScript-specific flags. The following flags are available:</p> <ul style="list-style-type: none"> <li>● <b>0</b>—Default behavior</li> <li>● <b>ISDIFX_OPTION_NO_REPAIR</b>—By default, the function automatically adds the DRIVER_PACKAGE_REPAIR flag when calling <b>DriverPackagePreinstall</b> if REINSTALLMODE is TRUE. If this flag is specified, DRIVER_PACKAGE_REPAIR is not added automatically. However, it is passed if it is specified in nFlags.</li> <li>● <b>ISDIFX_OPTION_LOG_IN_DRIVER_PACKAGE_PATH</b>—By default, the function logs the installed driver for uninstallation in the installed driver cache. If this flag is specified, the driver is logged in the package page instead.</li> <li>● <b>ISDIFX_OPTION_DONT_RESOLVE_TEXTSUBS</b>—By default, the function resolves any text substitutions found in <b>szDriverPackageInfPath</b>. If this flag is specified, text substitutions are not resolved.</li> </ul> |

## Return Values

**Table 155** ▪ DIFxDriverPackagePreinstall Return Values

| Return Value              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | The function was successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>&lt; ISERR_SUCCESS</b> | <p>The function failed.</p> <p>If the return value from <b>DriverPackagePreinstall</b> is a Win32 error (a positive return value), ISERR_WIN_BASE is added to the error to ensure that it is &lt; ISERR_SUCCESS.</p> <p>You can use the following code to get the original Win32 error, if desired:</p> <pre>if( nResult &amp; ISERR_WIN_BASE ) then nResult = nResult - ISERR_WIN_BASE; endif;</pre> <p>For a list of specific errors, see DIFxAPI Errors (InstallScript Projects).</p> |

## Additional Information

For more information on DIFx and DIFxAPI, see the [MSDN Library](#).

# DIFxDriverPackageUninstall

---

**Project** ▪ This function applies to InstallScript projects only. This function is not required in InstallScript MSI projects since DIFx can be called by the Windows Installer in those projects.

The **DIFxDriverPackageUninstall** function uninstalls the specified driver package from the system and removes the driver package from the driver store.

It is not necessary to call this function explicitly for drivers installed with **DIFxDriverPackageInstall** or **DIFxDriverPackagePreinstall** while uninstall logging is enabled as these drivers are automatically removed by the OnUninstallingDIFxDriverFile event.

---

**Note** ▪ This function calls the DIFxAPI function *DriverPackageUninstall*. See the DIFxAPI documentation for additional details regarding this function and its parameters and return values.

## Syntax

```
DIFxDriverPackageUninstall( byval string szDriverPackageInfPath, byval number nFlags, byval number  
    nISFlags );
```

## Parameters

**Table 156** ▪ DIFxDriverPackageUninstall Parameters

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDriverPackageInfPath</b> | String that supplies the fully qualified path to the driver package .inf file of the driver package to pre-install.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>nFlags</b>                 | <p>One or more flags that control the installation operation. In most cases, specify 0 to have the installer automatically add the appropriate flags.</p> <p>The following additional flags can be specified manually:</p> <div data-bbox="630 630 669 674" data-label="Image"> </div> <p><b>Note</b> ▪ These flags are defined by and passed directly to the <i>Flags</i> parameter of the DIFxAPI function <i>DriverPackageUninstall</i>. See the DIFxAPI documentation for additional information regarding these flags.</p> <ul style="list-style-type: none"> <li>• <b>DRIVER_PACKAGE_FORCE</b>—(Applies only to PnP function drivers) By default, installs a new driver for device only if the new driver is a better match for the device than the driver currently installed for the device. If you specify this flag, the function preinstalls and installs the specified driver package even if the driver package currently installed for a device is a better match for the device than the specified driver package.</li> <li>• <b>DRIVER_PACKAGE_SILENT</b>—Suppresses the display of user dialogs. If a user interaction is required to continue the installation, for example, in response to a driver signing dialog, the installation operation fails without displaying a user message. The function returns an error code that indicates the cause of the failure.</li> <li>• <b>DRIVER_PACKAGE_DELETE_FILES</b>—Removes the binary files from a system that were copied to the system when the driver package was installed. The function removes a binary file from the system only if the binary file is identical to the corresponding binary file in the driver store.</li> </ul> <div data-bbox="630 1381 669 1425" data-label="Image"> </div> <p><b>Caution</b> ▪ Use this flag with caution. Only use this flag if you can verify that a binary file in the system is not required by any other driver package or application.</p> |
| <b>nISFlags</b>               | <p>Specifies InstallScript-specific flags. The following flags are available:</p> <ul style="list-style-type: none"> <li>• <b>0</b>—Default behavior</li> <li>• <b>ISDIFX_OPTION_DONT_ASSOCIATE</b>—By default, the function associates the installed driver with the application being installed. If this flag is specified, the driver is not associated with any application.</li> <li>• <b>ISDIFX_OPTION_DONT_RESOLVE_TEXTSUBS</b>—By default, the function resolves any text substitutions found in <i>szDriverPackageInfPath</i>. If this flag is specified, text substitutions are not resolved.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Return Values

**Table 157** ▪ DIFxDriverPackageUninstall Return Values

| Return Value              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | The function was successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>&lt; ISERR_SUCCESS</b> | <p>The function failed.</p> <p>If the return value from <b>DriverPackageUninstall</b> is a Win32 error (a positive return value), ISERR_WIN_BASE is added to the error to ensure that it is &lt; ISERR_SUCCESS.</p> <p>You can use the following code to get the original Win32 error, if desired:</p> <pre>if( nResult &amp; ISERR_WIN_BASE ) then nResult = nResult - ISERR_WIN_BASE; endif;</pre> <p>For a list of specific errors, see DIFxAPI Errors (InstallScript Projects).</p> |

## Additional Information

- For more information on DIFx and DIFxAPI, see the [MSDN Library](#).
- When a driver is installed by **DIFxDriverPackageInstall** or uninstalled by **DIFxDriverPackageUninstall**, the driver is associated with the application being installed by the installation by default. This association can be disabled by specifying ISDIFX\_OPTION\_DONT\_ASSOCIATE. These functions use the following script variables to determine the application to associate:
  - [ISDIFXAPPID](#)
  - [IFX\\_PRODUCT\\_DISPLAY\\_NAME](#)
  - [IFX\\_PRODUCT\\_NAME](#)
  - [IFX\\_COMPANY\\_NAME](#)

## Disable

The **Disable** function deactivates the user interface object or setup feature specified by the parameter nConstant.

If your script calls the **Disable** function to disable the Next or Back button, that button is disabled in all dialogs displayed after that function call. To re-enable the Next or Back button, you must call [Enable](#) with the corresponding constant.

## Syntax

```
Disable ( nConstant );
```

## Parameters

**Table 158** ▪ Disable Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nConstant</b> | <p>Specifies the user interface object or operational feature to disable.</p> <p>Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>BACKBUTTON</b>—Disables (grays out) the Back button that is displayed in some built-in dialogs. The Back button is enabled by default.</li> <li>● <b>BACKGROUND</b>—Disables and hides the installation's main background window. Note that this parameter has no effect when the installation is in full-screen mode.</li> <li>● <b>BILLBOARD</b>—Suppresses the display of billboards during an installation.</li> <li>● <b>CANCELBUTTON</b>—Disables (grays out) the Cancel button that is displayed in some built-in dialogs.</li> <li>● <b>DIALOGCACHE</b>—Disables the dialog cache mechanism. For more information about dialog caching, see <a href="#">Enable</a>.</li> </ul> <hr/> <p> <b>Note</b> ▪ <i>DIALOGCACHE has no effect on dialogs that do not have a Next or Back button.</i></p> <ul style="list-style-type: none"> <li>● <b>HOURLASS</b>—Causes the mouse cursor to change from the “Busy” cursor (an hourglass by default), to a normal cursor (a pointer by default).</li> </ul> |

Table 158 ■ Disable Parameters (cont.)

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nConstant (cont.)</b> | <ul style="list-style-type: none"> <li> <b>LOGGING</b>—Disables the logging of uninstallation information so that no information is recorded in the uninstallation log file. <p>Note that logging is enabled automatically by default. If you need to disable logging, it is recommended that you do so by calling <b>Disable</b> with the LOGGING constant immediately before performing operations that should not be logged for uninstallation. Then you can re-enable logging by calling <b>Enable</b> with the LOGGING constant.</p> <p>For more information about logging, see InstallScript Functions that Are Logged for Uninstallation.</p> </li> </ul> <hr/> <p> <b>Tip</b> ■ To prevent changes that are made by a component from being undone during uninstallation, select <i>No</i> for the <i>Uninstall</i> setting of a component in an InstallScript project, or select <i>Yes</i> for the <i>Permanent</i> setting of a component in an InstallScript MSI project.</p> <ul style="list-style-type: none"> <li> <b>NEXTBUTTON</b>—Disables (grays out) the Next button that is displayed in some built-in InstallScript dialogs. On most dialogs, the Next button is enabled by default. </li> </ul> <hr/> <p> <b>Note</b> ■ Calling <b>Disable</b> with the NEXTBUTTON constant has no effect on the <b>SdCustomerInformation</b>, <b>SdCustomerInformationEx</b>, <b>SdRegisterUser</b>, or <b>SdRegisterUserEx</b> dialogs since they enable and disable the Next button internally.</p> <ul style="list-style-type: none"> <li> <b>PCRESTORE</b>—Disables System Restore compatibility, which is enabled by default. </li> <li> <b>REGISTRYFUNCTIONS_USETEXTSUBS</b>—Disables text substitutions in strings that are passed to registry functions; this is enabled by default. Use this option when working with registry function strings that contain opening angle brackets (&lt;) and closing angle brackets (&gt;) but that should not be interpreted as text substitutions. </li> <li> <b>SELFREGISTERBATCH</b>—Disables the “batch method” for registering files copied with <b>XCOPYFile</b> and the SELFREGISTER constant. The batch method is enabled by default. <p>When the batch method is disabled, files are registered immediately when copied with <b>XCOPYFile</b> and the SELFREGISTER constant. If the batch method is enabled, registration is postponed until data transfer takes place.</p> </li> </ul> |

**Table 158** ■ Disable Parameters (cont.)

| Parameter                                                                                                                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nConstant (cont.)</b>                                                                                                                                                                       | <ul style="list-style-type: none"> <li>● <b>SERVICE_DIFX_32</b>—Disables DIFx support for 32-bit platforms.</li> <li>● <b>SERVICE_DIFX_AMD64</b>—Disables DIFx support for AMD 64-bit platforms.</li> <li>● <b>SERVICE_DIFX_IA64</b>—Disables DIFx support for Itanium 64-bit platforms.</li> <li>● <b>SERVICE_ISFONTREG</b>—Disables global font registration. For details, see <a href="#">Installing Fonts Through InstallScript and InstallScript Object Projects</a>. Global font registration is enabled by default; once it is disabled, it cannot be re-enabled from the script.</li> <li>● <b>STATUS</b>—Disables and hides the progress indicator (status bar).</li> <li>● <b>STATUSBBRD</b>—Disables and hides the progress dialog that includes a billboard.</li> <li>● <b>STATUSDLG</b>—Disables and hides the dialog style progress indicator (status bar).</li> <li>● <b>STATUSEX</b>—Disables the display of the default Setup Status dialog.</li> <li>● <b>STATUSOLD</b>—Disables and hides the old style progress indicator (status bar).</li> <li>● <b>UPDATE_SERVICE_INSTALL</b>—This constant is obsolete.</li> <li>● <b>USE_LOADED_SKIN</b>—Intended for use with custom dialogs that will not work with dialog skins (for example, dialogs that are not the standard size); not recommended for use with built-in dialogs. Disables the use of the skin that you specified in the Specify Skin setting on the Build tab for the release in the Releases view. (If you selected the <b>&lt;Do not use any skin&gt; option</b> in that setting, this constant has no effect.) Disabling of the skin applies only to dialogs that are displayed after you call <code>Disable(USE_LOADED_SKIN)</code>; in your InstallScript code. To disable skin use for a custom dialog, you must call <code>Disable(USE_LOADED_SKIN)</code>; before calling <b>WaitOnDialog</b>. To re-enable skin use, call <code>Enable(USE_LOADED_SKIN)</code>; in your script.</li> </ul> |
|  <p><b>Project</b> ■ The <code>USE_LOADED_SKIN</code> constant is applicable to InstallScript projects.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                                                                                                                                                                                | <ul style="list-style-type: none"> <li>● <b>WOW64FSREDIRECTION</b>—Disables 64-bit Windows file system redirection. You may need to do this before installing files to the <b>WINSYSDIR64</b> destination. To learn more, see <a href="#">Targeting 64-Bit Operating Systems with InstallScript Installations</a>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Return Values

**Table 159** ▪ Disable Return Values

| Return Value  | Description                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully disabled the user interface object or setup feature specified by the parameter nConstant. |
| <b>&lt; 0</b> | Indicates that the function was unable to disable the user interface object or setup feature specified by the parameter nConstant. |

## Disable Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the Disable and Enable functions.
 *
 * This script displays two dialogs. In the first box, the
 * Back button is disabled. In the second box, the Next button
 * is disabled and the Back button enabled.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_Disable(HWND);

function ExFn_Disable(hMSI)
begin

start:

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // The following displays a dialog with the Back button disabled.
    SetupType ("", "", "", TYPICAL, 0);

    // Enable the Back button,
    Enable (BACKBUTTON);

    // Next button is disabled.
    Disable (NEXTBUTTON);

    // The following displays a dialog with only the Back button enabled.
    if (SetupType ("", "", "", TYPICAL, 0) = BACK) then
        // If the Back button is pressed, the Next button is enabled.
        Enable (NEXTBUTTON);
        goto start;
    endif;

```

```
end;
```

## Do

The **Do** function executes the currently defined EXIT and HELP handlers, giving you greater control over these handlers, which are normally executed only when the user presses the F1 key (HELP) or the Cancel button (EXIT). Using the **Do** function, you can execute EXIT or HELP handlers in response to custom dialog events or to any user input from built-in dialogs. You can also use the **Do** function during script development to test your EXIT and HELP handlers.

The **Do** function can also register queued self-registering files. Files are queued for registration using the “batch method” for installing self-registering files. When you call `Do(SELFREGISTRATIONPROCESS)`, the installation carries out self-registration of all queued files, even if one of them fails. (Note that when you call [FeatureTransferData](#), `Do(SELFREGISTRATIONPROCESS)` is called automatically after the files are installed but before the **FeatureTransferData** call returns. If you use an event-based script, the **FeatureTransferData** function is called by the default code for the **OnMoveData** event handler function.)

### Syntax

```
Do (nOperation);
```

## Parameters

**Table 160** ▪ Do Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOperation</b> | <p>Specifies the type of operation to perform. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>EXIT</b>—Initiates the Exit operation. If no EXIT handler is defined, the default Exit dialog is displayed.</li> <li>● <b>HELP</b>—Initiates the Help operation. If no HELP handler is defined, the function takes no action.</li> <li>● <b>SELFREGISTRATIONPROCESS</b>—Registers all self-registering files that have been queued for registration.</li> </ul> |

## Return Values

**Table 161** ▪ Do Return Values

| Return Value  | Description                                                            |
|---------------|------------------------------------------------------------------------|
| <b>0</b>      | The <b>Do</b> function successfully initiated the specified operation. |
| <b>&lt; 0</b> | The <b>Do</b> function was unable to initiate the specified operation. |

## Additional Information

- The **Do** function allows the currently defined HELP and EXIT handlers to execute without the end user pressing F1. The **Do** function also provides more versatility than the goto statement, which can be used to call HELP and EXIT handler labels. The goto statement cannot be used in all circumstances, but the **Do** function can be called virtually anytime. For more information on default and custom HELP and EXIT handlers, see [HandlerEx](#).
- If **Do** fails for any reason, it returns -1. The names of the files that failed to self-register are stored in the InstallScript system variable ERRORFILENAME, and each is separated by a semicolon (;).

## Do Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the Do function.
*
```

```

* This script calls Do to test the HELP and EXIT handler.
*
* Note: Before running this script, set the preprocessor
*       constant so that it references a valid
*       help file on the target system.
*
/*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

#define HELPFILE WINDIR^"Help\\Windows.chm"

    export prototype ExFn_Do(HWND);

function ExFn_Do(hMSI)
begin

    // Install the exit handler.
    HandlerEx (EXIT, Exit_Handler);

    // Install the help handler.
    HandlerEx (HELP, Help_Handler);

    // Execute loop forever -- or until user aborts.
    while (TRUE)
        if (AskYesNo ("View the help?", NO) = YES) then
            // Execute the help handler.
            Do (HELP);
        endif;

        // Execute the exit handler.
        Do (EXIT);
    endwhile;

// The exit handler.
Exit_Handler:

    // Ask for confirmation to abort.
    if (AskYesNo ("Do you really want to exit?", NO) = YES) then
        abort;
    else
        // Continue if not sure.
        return;
    endif;

// The help handler.
Help_Handler:

    // Display the help.
    LaunchApplication (HELPFILE, "", "", SW_SHOW, INFINITE, LAAW_OPTION_WAIT);
    return;

end;

```

# DoInstall

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **DoInstall** function launches another InstallShield installation that has a valid setup executable file (.exe). The second installation is executed immediately when this function is called. The third parameter, *nOptions*, specifies various options, including whether the installation should wait until the launched application terminates before continuing.

**Note** ▪ **DoInstall** cannot be used directly to launch a .msi file. In addition, because **DoInstall** adds command-line parameters that are specific to InstallShield installations, **DoInstall** should not be used to launch a non-InstallShield installation. To launch a non-InstallShield installation, use the **LaunchApplication** function.

## Syntax

```
DoInstall ( byval string szSetupExe, byval string szCmdLine, byval number nOptions );
```

Parameters

**Table 162** ▪ DoInstall Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSetupExe</b> | <p>Specifies the fully qualified name—including a drive designation and complete path—of the setup executable file to be launched.</p> <p>Alternatively, you can specify the compiled script file of the installation to be launched. For InstallScript MSI installations, you can specify the installation's .msi package. Note that in order to be able to use <b>DoInstall</b>, your installation must include a valid setup executable file named Setup.exe, or an alternative name, as described in <a href="#">Additional Information</a>.</p> |
| <b>szCmdLine</b>  | <p>Specifies the command line for the launched installation. You can specify any valid startup InstallShield command line for this parameter. Note that <b>DoInstall</b> automatically adds some command-line switches, depending on the <i>nOptions</i> specified.</p> <p><b>Note</b> ▪ Unlike with previous versions of InstallShield, if you are passing command-line parameters to a child InstallScript MSI installation, you must pass these options through the /z parameter (as when launching the installation directly).</p>               |

**Table 162** ▪ DoInstall Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOptions</b> | <p>Specifies options for launching the installation. You can specify any valid <b>LaunchApplication</b> option, including:</p> <ul style="list-style-type: none"> <li>• <b>LAAW_OPTION_NOWAIT</b></li> <li>• <b>LAAW_OPTION_WAIT</b></li> </ul> <p>You can also specify some additional options that apply only to <b>DoInstall</b>:</p> <ul style="list-style-type: none"> <li>• <b>DOINSTALL_OPTION_NOHIDEPROGRESS</b>—Specifies that the entire initialization user interface, including the initial progress dialog and splash screen (if any), should be displayed for the child installation.</li> </ul> <p>If this option is not specified, <b>DoInstall</b> automatically hides the initialization user interface of the child installation by using the <code>/hide_progress</code> option.</p> <ul style="list-style-type: none"> <li>• <b>DOINSTALL_OPTION_NOHIDESPLASH</b>—Specifies that the splash screen (if any) should be displayed for the child installation that is being launched.</li> <li>• <b>DOINSTALL_OPTION_NOLANGSWITCH</b>—Specifies that the <code>/1</code> switch will not be specified.</li> </ul> <p>By default, <b>DoInstall</b> adds the <code>/1</code> switch to <code>szCmdLine</code> so that the launched installation runs in the same language as the launching installation. Note that if the child installation does not support the language in which the parent installation is running (as determined by calling <b>Is(LANGUAGE_SUPPORTED)</b>), the <code>/1</code> switch is not added.</p> <ul style="list-style-type: none"> <li>• <b>DOINSTALL_OPTION_NOSETBATCHINSTALL</b>—Specifies that <b>DoInstall</b> should not use the <b>LAAW_OPTION_SET_BATCH_INSTALL</b> option to determine whether the child installation performed actions that require a reboot. Thus, <b>BATCH_INSTALL</b> for the parent installation will not be changed by <b>DoInstall</b>, regardless of the actions of the child installation.</li> </ul> <p>By default, <b>DoInstall</b> automatically uses the <b>LAAW_OPTION_SET_BATCH_INSTALL</b> option.</p> <p>You can combine these constants by using the bitwise OR operator (<code> </code>). Note that combining <b>DOINSTALL_OPTION_NOSETBATCHINSTALL</b> with <b>LAAW_OPTION_SET_BATCH_INSTALL</b> may lead to unexpected results.</p> |

## Return Values

**Table 163** • DoInstall Return Values

| Return Value                             | Description                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                        | If <b>DoInstall</b> was called with LAAW_OPTION_WAIT as the third argument, the installation launched by <b>DoInstall</b> terminated successfully. 0 is always returned when <b>DoInstall</b> is called with LAAW_OPTION_NOWAIT as the third argument. Control resumes in the calling installation with the statement that follows the <b>DoInstall</b> function. |
| <b>ISERR_SETUP_CANCELED (0x80042000)</b> | The InstallScript installation launched by <b>DoInstall</b> with LAAW_OPTION_WAIT as the third argument exited with the abort keyword. This usually indicates that the user canceled the installation.                                                                                                                                                            |
| <b>-3</b>                                | The InstallScript MSI installation launched by <b>DoInstall</b> with LAAW_OPTION_WAIT as the third argument exited with the abort keyword. This usually indicates that the user canceled the installation.                                                                                                                                                        |
| <b>All other negative values</b>         | An unspecified error has occurred.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <b>FormatMessage</b> .                                                                                                                                                             |

## Additional Information

- By default, **DoInstall** automatically attempts to launch the specified setup executable file. If a non-executable file name is specified in szSetupExe, the function attempts to launch Setup.exe in the specified folder. If the installation's executable file has a name other than *Setup*, the launched installation's Setup.ini file must have the new name of Setup.exe in the [Startup] section's LauncherName key.

**Project** • If you specify a value for the **Setup File Name** setting for a release in the Releases view of an InstallScript MSI project and then build the release, InstallShield automatically adds file name value to Setup.ini. If you rename the setup launcher executable file in an InstallScript project, you must add the name to the Setup.ini file manually.

- When the installation is run from any removable media, such as a CD or a DVD, the Setup.exe file on Disk1 may not be available during the entire installation. (If Setup.exe becomes unavailable while it is running, the operating system sometimes displays a prompt to request that the end user insert the correct disk, and this may cause the installation to fail.) Therefore, to avoid this problem, the Setup.exe file is copied to a Temp folder, and the installation is relaunched from there. The original Setup.exe then terminates. However, when this happens, **DoInstall** behaves as if the installation has completed, and it does not wait.

To avoid this issue, you may want to use the /clone\_wait parameter when you are launching the child installation; when this occurs, the launched installation keeps the original launched process running, and the parent installation then waits. Note, however, that this may cause problems if the original CD containing Setup.exe is not available throughout the entire installation. This includes multiple-CD installations, where the first CD is not available during some parts of the installation.

The only other way to avoid this problem is to add code that determines the ID of the child processes of the launched process and wait for the child process to complete.

## DoInstall Example

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DoInstall function.
*
* This example script runs the MessageBox example script
* using the DoInstall function.
*
* Note: To make this example work correctly you must also do
*       the following:
*
*       1. Create a second setup project. This setup will be
*          launched by the DoInstall function. This project
*          should include an up-to-date built release.
*
*       2. Create a new folder named 'Second' in the disk1
*          folder of this setup.
*
*       3. Copy the disk# folder(s) from the second setup
*          into the newly created 'Second' folder.
*
*       The second setup should then be launched successfully.
*
\*-----*/

#define SECOND_INSTALL_PATH SRCDIR ^ "Second\\Disk1"
#define SECOND_INSTALL_FILENAME "Setup.exe"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_DoInstall(HWND);

function ExFn_DoInstall(hMSI)
    NUMBER nReturn;
    STRING szTemp;
begin

    MessageBox ("About to launch the second setup.", INFORMATION);

    // Launch the second setup.
    nReturn = DoInstall (SECOND_INSTALL_PATH ^ SECOND_INSTALL_FILENAME, "",
                        LAAW_OPTION_WAIT);
```

```

    if ( nReturn = 0) then
        // Report successful second setup launch.
        MessageBox("The second setup was launched successfully.", INFORMATION);
    else
        // Report failure to launch second setup.
        sprintfBox(SEVERE, "", "DoInstall failed with a return code of %d.", nReturn);
    endif;

end;

```

## DotNetCoCreateObject

**Project** ▪ The following project types support the **DotNetCoCreateObject** function:

- *InstallScript*
- *InstallScript MSI*
- *Basic MSI with InstallScript custom actions*

The **DotNetCoCreateObject** function calls functions in .NET assemblies without the assembly being registered for COM interoperability. This function lets you specify the .NET application domain in which the .NET assemblies should be loaded and run. Each object created with this function is associated with a single class in a single .NET assembly. If you want to access multiple classes in the same assembly, you must create a separate object for each class.

**Important** ▪ The assembly does not have to be registered as a COM component, but the assembly must be built to be compatible with COM interoperability. Assemblies built with Visual Studio .NET 2003 and earlier are automatically built with this compatibility. However, projects created with Visual Studio 2005 must manually specify `[assembly: ComVisible(true)]` in the appropriate file.

### Syntax

```

DotNetCoCreateObject ( byval string szAssemblyPathFile, byval string szAssemblyAndClassName, byval
    string szAppDomain );

```

## Parameters

**Table 164** • DotNetCoCreateObject Parameters

| Parameter                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szAssemblyPathFile</b>     | Specifies the full path and file name of the .NET assembly that contains the appropriate class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>szAssemblyAndClassName</b> | <p>Specifies the assembly and class name.</p> <div>  <p><b>Note</b> • This value is the same as the <i>szProgId</i> parameter if the assembly is registered for COM interoperability using the <b>CoCreateObject</b> function.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>szAppDomain</b>            | <p>Specifies the .NET application domain to load and run the assembly in. If the specified application domain does not exist in the installation process, it is created; otherwise, the existing application domain is used. This is true if you call <b>DotNetCoCreateObject</b> multiple times with the same <i>szAppDomain</i>.</p> <p>If you specify a null string ("") for this parameter or call <b>CoCreateObjectDotNet</b> instead of <b>DotNetCoCreateObject</b>, the assembly is loaded into the default application domain after the installation completes; thus, the .NET assembly file is locked until the installation has finished.</p> <p>For more information on .NET application domains, see the .NET Framework Developer's Guide in the MSDN Library.</p> |

## Return Values

The reference can be assigned to a variable of type OBJECT by using the set keyword.

## Additional Information

- The **DotNetCoCreateObject** function is similar to the **CoCreateObjectDotNet** function. The only difference is that with **DotNetCoCreateObject**, you can specify the .NET application domain that should be loaded; the assembly is then run in this domain.

For **CoCreateObjectDotNet**, the .NET assembly is loaded into the default application domain after the installation completes; thus, the .NET assembly file is locked until the installation has finished.

- Any object variable can be released by setting the object variable to the value of NOTHING or reassigning the object with the **CoCreateObject**, **CoCreateObjectDotNet**, **CoGetObject**, or **DotNetCoCreateObject** functions. However, this does not automatically unload the library referenced by the object. You must call the Windows API **CoFreeLibrary** manually to free the library. Otherwise, the library remains loaded until the installation finishes. For more information, see Extending Your Installation with COM Objects.

- This function throws an exception if the object cannot be created. This can occur if the .NET Framework is not installed on the system, or for other reasons. To handle this exception, surround calls to this function with try...catch blocks. For more information, see [Exception Handling](#).

## DotNetUnloadAppDomain

**Project** ▪ The following project types support the **DotNetUnloadAppDomain** function:

- *InstallScript*
- *InstallScript MSI*
- *Basic MSI with InstallScript custom actions*

The **DotNetUnloadAppDomain** function unloads the specified .NET application domain and releases any assemblies that are currently loaded into the specified application domain.

**Note** ▪ Once an application domain is unloaded, all .NET objects that were created with **DotNetCoCreateObject** become invalid. Therefore, you should set these objects to NOTHING using the set command before calling **DotNetUnloadAppDomain**.

### Syntax

```
DotNetUnloadAppDomain ( byval string szAppDomain );
```

### Parameters

**Table 165** ▪ DotNetUnloadAppDomain Parameters

| Parameter          | Description                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szAppDomain</b> | Specifies the .NET application domain to be unloaded.<br><br>For more information on .NET application domains, see the .NET Framework Developer's Guide in the MSDN Library. |

### Return Values

**Table 166** ▪ DotNetUnloadAppDomain Return Values

| Return Value               | Description                           |
|----------------------------|---------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The domain was successfully unloaded. |
| <b>&lt; ISERR_SUCCESS</b>  | The domain was not unloaded.          |

# Built-In Functions (E-G)

For a list of functions by category, see [Built-In Functions by Category](#).

## Enable

The **Enable** function activates the user interface object or setup feature specified by the parameter nConstant.

By default, an installation runs without a background. To enable window mode, you must call **Enable** with the BACKGROUND constant, and then again with DEFWINDOWMODE or FULLWINDOWMODE. These constants are not supported for use in Basic MSI installations.

---

**Note** ▪ If your script calls the **Disable** function to disable the Next or Back button, that button is disabled in all dialogs displayed after that function call. To re-enable the Next or Back button, you must call **Enable** with the corresponding constant.

### Syntax

```
Enable ( nConstant );
```

## Parameters

**Table 1** • Enable Parameters

| Parameter                                                                                                                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nConstant</b>                                                                                                                                                                             | <p>Specifies the user interface object or operational feature you want to enable. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>BACKBUTTON</b>—Enables the Back button that is displayed in some built-in dialogs. The Back button is enabled by default, but it can be disabled by calling the <b>Disable</b> function.</li> <li>• <b>BACKGROUND</b>—Displays the installation's main background window when the installation is in window mode. When installation is in full-screen mode, which is the default mode, this constant has no effect. To enable window mode, you must call <b>Enable</b> with the constant <b>DEFWINDOWMODE</b> or <b>FULLWINDOWMODE</b>.</li> <li>• <b>CANCELBUTTON</b>—Enables the Cancel button that is displayed in some built-in dialogs and the status dialog.</li> <li>• <b>DEFWINDOWMODE</b>—Configures the main background window to be a normal window with a title bar. If the background window is enabled, its appearance changes immediately. If the background window is not enabled, no change to the screen occurs until <b>Enable</b> is called with the constant <b>BACKGROUND</b>.</li> <li>• <b>DIALOGCACHE</b>—Enables the dialog cache mechanism, which eliminates the screen flash that appears between the display of dialogs. This screen flash is most noticeable in the title bar of installations running in window mode. Note that the dialog caching mechanism works only for dialogs that have <b>BACK</b> and <b>NEXT</b> buttons. Dialog caching is enabled by default.</li> </ul> |
|  <p><b>Note</b> • <i>DIALOGCACHE has no effect on dialogs that do not have a Next or Back button.</i></p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                                                                                                                                                                              | <ul style="list-style-type: none"> <li>• <b>FULLWINDOWMODE</b>—Configures the main background window to be a maximized window with a title bar. If the background window is enabled, its appearance will change immediately. If the background window is not enabled, no change to the screen will occur until <b>Enable</b> is called with the constant <b>BACKGROUND</b>.</li> <li>• <b>HOURLASS</b>—Causes the mouse cursor to change to the “Busy” cursor, an hourglass by default.</li> <li>• <b>INDVFILESTATUS</b>—Enables the display (on the second line of the progress indicator) of the fully qualified file name of each file as it is transferred when <b>FeatureMoveData</b>, <b>CopyFile</b>, or <b>XCopyFile</b> is called and the progress indicator is enabled.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 1** ■ Enable Parameters (cont.)

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nConstant (cont.)</b> | <ul style="list-style-type: none"> <li> <b>LOGGING</b>—Enables the logging of uninstallation information. When logging is enabled, results of operations that the InstallScript engine logs for uninstallation are recorded in the uninstallation log file and are reversed during uninstallation.<br/><br/> Note that logging is enabled automatically by default. If you need to disable logging, it is recommended that you do so by calling <b>Disable</b> with the <b>LOGGING</b> constant immediately before performing operations that should not be logged for uninstallation. Then you can re-enable logging by calling <b>Enable</b> with the <b>LOGGING</b> constant.<br/><br/> For more information about logging, see <i>InstallScript Functions that Are Logged for Uninstallation</i>. </li> <li> <b>NEXTBUTTON</b>—Enables the Next button that is displayed by some built-in dialogs. On most dialogs, the Next button is enabled by default. </li> </ul> <hr/> <p> <b>Note</b> ■ Calling <b>Enable</b> with the <b>BACKBUTTON</b> constant has no effect on the <b>SdCustomerInformation</b>, <b>SdCustomerInformationEx</b>, <b>SdRegisterUser</b>, or <b>SdRegisterUserEx</b> dialogs since they enable and disable the Next button internally.</p> <ul style="list-style-type: none"> <li> <b>PCRESTORE</b>—Enables System Restore compatibility, which is enabled by default. </li> <li> <b>REGISTRYFUNCTIONS_USETEXTSUBS</b>—Enables text substitutions in strings that are passed to registry functions; this is enabled by default. </li> <li> <b>SELFREGISTERBATCH</b>—Specifies whether to use the “batch method” for registering files copied with <b>XCOPYFile</b> and the <b>SELFREGISTER</b> constant. The batch method is enabled by default.<br/><br/> When the batch method is disabled, files are registered immediately when copied with <b>XCOPYFile</b> and the <b>SELFREGISTER</b> constant. If the batch method is enabled, registration is postponed until data transfer takes place. </li> <li> <b>SERVICE_DIFX_32</b>—Enables DIFx support for 32-bit platforms. </li> <li> <b>SERVICE_DIFX_AMD64</b>—Enables DIFx support for AMD 64-bit platforms. </li> <li> <b>SERVICE_DIFX_IA64</b>—Enables DIFx support for Itanium 64-bit platforms. </li> <li> <b>STATUS</b>—Enables the display of the progress indicator (status bar). </li> <li> <b>STATUSBBD</b>—Enables the display of the progress dialog that includes a billboard. </li> <li> <b>STATUSDLG</b>—Enables the display of the dialog style progress indicator (status bar). </li> <li> <b>STATUSSEX</b>—Enables the display of the standard Setup Status dialog. </li> <li> <b>STATUSOLD</b>—Enables the display of the old style progress indicator (status bar), which does not have a Cancel button. </li> </ul> |

**Table 1** • Enable Parameters (cont.)

| Parameter                                                                                                                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nConstant (cont.)</b>                                                                                                                                                                     | <ul style="list-style-type: none"> <li>● <b>UPDATE_SERVICE_INSTALL</b>—This constant is obsolete.</li> <li>● <b>USE_LOADED_SKIN</b>—Intended for use with custom dialogs that will not work with dialog skins (for example, dialogs that are not the standard size); not recommended for use with built-in dialogs. Enables the use of the skin that you specified in the Specify Skin setting on the Build tab for the release in the Releases view. (If you selected the <b>&lt;Do not use any skin&gt;</b> option in that setting, this constant has no effect.) If you specify a skin, it is displayed by default; <code>Disable(USE_LOADED_SKIN)</code>; and <code>Enable(USE_LOADED_SKIN)</code>; are called internally by functions that display dialogs that cannot be displayed with a skin. Enabling of the skin applies only to dialogs that are displayed after you call <code>Enable(USE_LOADED_SKIN)</code>; in your script. To enable skin use (after disabling it) for a custom dialog, you must call <code>Enable(USE_LOADED_SKIN)</code>; before calling <b>WaitOnDialog</b>.</li></ul> |
|  <p><b>Project</b> • The <code>USE_LOADED_SKIN</code> constant is applicable to InstallScript projects.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                                                                                                                                                                              | <ul style="list-style-type: none"> <li>● <b>WOW64FSREDIRECTION</b>—Enables 64-bit Windows file system redirection. You may need to do this after installing files to the <code>WINSYDIR64</code> destination. To learn more, see Targeting 64-Bit Operating Systems with InstallScript Installations.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Return Values

**Table 2** • Enable Return Values

| Return Value  | Description                                                                                                                       |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully enabled the user interface object or setup feature specified by the parameter nConstant. |
| <b>&lt; 0</b> | Indicates that the function was unable to enable the user interface object or setup feature specified by the parameter nConstant. |

## Enable Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the Disable and Enable functions.
 *
 * This script displays two dialogs. In the first box, the
 * Back button is disabled. In the second box, the Next button
 * is disabled and the Back button enabled.
 *
 \*-----*/

```

```
// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_Enable(HWND);

function ExFn_Enable(hMSI)
begin

start:

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // The following displays a dialog with the Back button disabled.
    SetupType ("", "", "", TYPICAL, 0);

    // Enable the Back button,
    Enable (BACKBUTTON);

    // Next button is disabled.
    Disable (NEXTBUTTON);

    // The following displays a dialog with only the Back button enabled.
    if (SetupType ("", "", "", TYPICAL, 0) = BACK) then
        // If the Back button is pressed, the Next button is enabled.
        Enable (NEXTBUTTON);
        goto start;
    endif;

end;
```

## EndCurrentDialog

**Project** ▪ This information applies to InstallScript projects.

The **EndCurrentDialog** function closes the currently displayed dialog by calling [EndDialog](#). It removes the dialog and initiates the dialog closing process.

### Syntax

```
EndCurrentDialog ( );
```

### Parameters

None

## Return Values

**Table 3** ▪ EndCurrentDialog Return Values

| Return Value                     | Description                                      |
|----------------------------------|--------------------------------------------------|
| <code>&gt;= ISERR_SUCCESS</code> | EndCurrentDialog successfully closed the dialog. |
| <code>&lt; ISERR_SUCCESS</code>  | No dialog is currently displayed.                |

## EndDialog

The **EndDialog** function closes a custom dialog. It removes the dialog and initiates the dialog closing process. Use EndDialog when any of the following conditions exist:

- The Next button or its equivalent has been processed.
- The Cancel button or its equivalent has been processed.
- The Close system menu option has been selected. This action sends the DLG\_CLOSE message.
- Any other situation in which the user ends the dialog operation.

After calling EndDialog to end a custom dialog, call the [ReleaseDialog](#) function to free the memory associated with the custom dialog.

**Note** ▪ You can call [WaitOnDialog](#) to redisplay a custom dialog that was closed by a call to EndDialog provided that you have not called ReleaseDialog to remove the dialog from memory. If you call WaitOnDialog to open a dialog that has been opened and closed previously in your script, you must call [CmdGetHwndDlg](#) again to get the new handle. The old handle is no longer valid.

## Syntax

```
EndDialog ( szDialogName );
```

## Parameters

**Table 4** • EndDialog Parameters

| Parameter           | Description                                |
|---------------------|--------------------------------------------|
| <b>szDialogName</b> | Specifies the name of the dialog to close. |

## Return Values

**Table 5** • EndDialog Return Values

| Return Value  | Description                               |
|---------------|-------------------------------------------|
| <b>0</b>      | EndDialog successfully closed the dialog. |
| <b>&lt; 0</b> | EndDialog was unable to close the dialog. |

## EndDialog Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DefineDialog, EndDialog, and ReleaseDialog
* functions.
*
* This script opens a simple custom dialog that displays
* a bitmap. The dialog can be closed with any of three
* buttons: Back, Next, or Cancel.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdBitmap. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
* In order to use this dialog as a custom dialog, the
* script first defines it by calling DefineDialog. It then
* displays the dialog by calling WaitOnDialog. When an event
* ends dialog processing, EndDialog is called to close the
* dialog. Then the dialog is released from memory by
* a call to ReleaseDialog.
*
\*-----*/
```

```

// Dialog and control IDs.
#define RES_DIALOG_ID      12027  // ID of dialog itself
#define RES_PBUT_NEXT      1      // ID of Next button
#define RES_PBUT_CANCEL    9      // ID of Cancel button
#define RES_PBUT_BACK      12     // ID of Back button

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EndDialog(HWND);

    // Define the name of a dialog to pass as first
    // parameter to DefineDialog.
    szDialogName = "ExampleDialog";

    // DefineDialog's second parameter will be 0 because the
    // .dll file is in _isres.dll.
    hInstance = 0;

    // DefineDialog's third parameter will be null; installation
    // will search for the dialog in _isuser.dll and _isres.dll.
    szDLLName = "";

    // DefineDialog's fifth parameter will be null because the
    // dialog is identified by its ID in the fourth parameter.
    szDialog = "";

    // This value is reserved and must be 0.
    hwndParent = 0;

    // Define the dialog. The installation's main window will own the
    // dialog (indicated by HWND_INSTALL in parameter 7).
    nResult = DefineDialog (szDialogName, hInstance, szDLLName,
                           RES_DIALOG_ID, szDialog, hwndParent,
                           HWND_INSTALL, DLG_MSG_STANDARD|DLG_CENTERED);

    // Check for an error.
    if (nResult < 0) then
        MessageBox ("An error occurred while defining the dialog.", SEVERE);
        bDone = TRUE;
        abort;
    endif;

    // Initialize the indicator used to control the while loop.
    bDone = FALSE;

    // Loop until done.
    repeat

```

```

// Display the dialog and return the next dialog event.
nCmdValue = WaitOnDialog(szDialogName);

// Respond to the event.
switch (nCmdValue)
case DLG_CLOSE:
    // The user clicked the window's Close button.
    Do (EXIT);
case DLG_ERR:
    MessageBox ("Unable to display dialog. Setup canceled.", SEVERE);
    abort;
case DLG_INIT:
    // Initialize the back, next, and cancel button enable/disable states
    // for this dialog and replace %P, %VS, %VI with
    // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
    // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
    hwndDlg = CmdGetHwndDlg(szDialogName);
    SdGeneralInit(szDialogName, hwndDlg, 0, "");
case RES_PBUT_CANCEL:
    // The user clicked the Cancel button.
    Do (EXIT);
case RES_PBUT_NEXT:
    bDone = TRUE;
case RES_PBUT_BACK:
    bDone = TRUE;
endswitch;

until bDone;

// Close the dialog.
EndDialog (szDialogName);

// Free the dialog from memory.
ReleaseDialog (szDialogName);

end;

```

## EnterDisk

**Project** ▪ This information applies to the following project types:

- Basic MSI
- InstallScript
- InstallScript MSI

The **EnterDisk** function displays a message box that prompts the end user to insert the next disk. The system variable **SRCDIR** contains the default path, which is displayed on the message box. The end user can modify the default path by typing a new path and clicking OK.

**EnterDisk** recognizes the correct disk by searching the disk for the tag file specified by szTagFile. If the disk does not contain the tag file, the function calls the **EnterDiskError** function to display an error message box that prompts the end user to enter the correct disk. At build time, InstallShield does not automatically generate tag files in the disk image folders. To use tag files, add them to the disk image folders after the folders are built.

**Note** • You cannot use the *PlaceWindow* function in conjunction with the **EnterDisk** function. By default, the message box appears in the center of the desktop, unless the background window mode is enabled. If the installation is in window mode, the message box opens in the center of the background window.

The default title is *Setup Needs the Next Disk*. To change the title, call *SetDialogTitle* before calling **EnterDisk**.

Syntax

EnterDisk (szMsg, szTagFile);

Parameters

Table 6 • EnterDisk Parameters

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| szMsg     | Specifies the message that prompts the end user to insert the proper disk.                                                                                                                                                                                                                                                                                                                         |
| szTagFile | Specifies the name of the tag file. <b>EnterDisk</b> searches for this file on the inserted disk. If the file is not found, the function calls the <b>EnterDiskError</b> function to display a message that asks the user to insert the correct disk. If you pass a null string ("") in this parameter, the function does not search for any file; it assumes that the correct disk is being used. |

Return Values

Table 7 • EnterDisk Return Values

| Return Value | Description                                       |
|--------------|---------------------------------------------------|
| OK (1)       | Indicates that the user clicked the OK button.    |
| < 0          | Indicates that an unspecified error has occurred. |

Additional Information

The dialog that is displayed by the **EnterDisk** function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

EnterDisk Example

**Project** • This information applies to the following project types:

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* This example demonstrates the EnterDisk function.
*
* EnterDisk is called to prompt the user to insert a disk or
* to specify a path. EnterDisk then searches for the tag file
* at that location.
*
\*-----*/

#include "ifx.h"

    export prototype ExFn_EnterDisk(HWND);

function ExFn_EnterDisk(hMSI)
    STRING szMsg, szTagFile;
begin

    // Set up parameters for call to EnterDisk.
    szMsg      = "Please insert disk 2";
    szTagFile = "ISExempl.txt";

    // Display the EnterDisk dialog.
    EnterDisk (szMsg, szTagFile);

end;
```

## EnterDiskError

**Project** ▪ This information applies to the following project types:

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

The **EnterDiskError** function checks whether a specified path and file exists. The function displays an appropriate error if the file does not exist in the specified path; then it returns success or failure, depending on whether the specified file exists.

**Tip** • **EnterDiskError** can also check for the presence of a specific path, without a particular file.

## Syntax

```
EnterDiskError (byval string szPath, byval string szFile);
```

## Parameters

**Table 8** • EnterDiskError Parameters

| Parameter     | Description                                                                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPath</b> | Specify the path to be checked.                                                                                                                                  |
| <b>szFile</b> | Specify the name of the file to be checked.<br><br>If you want <b>EnterDisk</b> to check for just the path, but not a specific file, specify a null string (""). |

## Return Values

**Table 9** • EnterDiskError Return Values

| Return Value               | Description                               |
|----------------------------|-------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The specified path and file exist.        |
| <b>&lt; ISERR_SUCCESS</b>  | The specified path and file do not exist. |

## Additional Information

Since the **EnterDiskError** function is typically called only internally by the **EnterDisk** function, it does not include any silent mode handling, other than the normal **MessageBox** silent mode handling.

By default, the dialog displays the same error message and the default message box title for the installation, regardless of the error that occurs. You can change this behavior by calling the **SetErrorTitle** and **SetErrorMsg** functions with **nErrorId** set as follows:

- **ERR\_BOX\_DISKID**—Customize the title or message displayed when the specified disk does not exist.
- **ERR\_BOX\_BADPATH**—Customize the title or message displayed when the specified path does not exist.
- **ERR\_BOX\_BADTAGFILE**—Customize the title or message displayed when the specified file does not exist. (If a null string ("") is specified for **szFile**, no error check occurs, and no message is displayed.)

# EnterLoginInfo

**Project** • This information applies to the following project types.

- *InstallScript*
- *InstallScript MSI*

The **EnterLoginInfo** function displays a dialog that enables the end user to specify a user name and password. Note that the dialog does not validate or use the specified information. In addition, the dialog does not perform any error checking for the specified information.

The **EnterLoginInfo** dialog is typically used to let the end user specify a network user name and password. The **SdLogonUserInformation** dialog is similar to the **EnterLoginInfo** dialog, but the **SdLogonUserInformation** dialog provides additional options. If your installation needs to obtain information to log into a SQL Server, **SQLServerLogin** offers additional functionality.

## Syntax

```
EnterLoginInfo (byval string szMsg, byref string svUser, byref string svPassword);
```

## Parameters

**Table 10** ▪ EnterLoginInfo Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b>      | Specifies the static text to be displayed in the dialog. To display the default text, pass a null string ("") in this parameter.                                                                                                                                                               |
| <b>svUser</b>     | <p>Specifies the default value that is initially displayed in the User Name box when the function is called, and specifies the string that the end user specified when the function returns.</p> <p>The dialog does not allow more than 255 characters to be entered in the User Name box.</p> |
| <b>svPassword</b> | <p>Specifies the default value that is initially displayed in the Password box when the function is called, and specifies the string that the end user specified when the function returns.</p> <p>The dialog does not allow more than 255 characters to be entered in the Password box.</p>   |

## Return Values

**Table 11** ▪ EnterLoginInfo Return Values

| Return Value               | Description                      |
|----------------------------|----------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function was successful.     |
| <b>&lt; ISERR_SUCCESS</b>  | The function was not successful. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

# EnterPassword

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **EnterPassword** function displays a dialog that queries the end user for a password; the characters that the end user types in the edit box are displayed as asterisks (\*).

**Note** ▪ To check the returned password, you can call *FeatureValidate*, as is done in the default code for the *OnCheckMediaPassword* event handler function.

## Syntax

```
EnterPassword ( szMsg, szDefault, svResult );
```

## Parameters

**Table 12** ▪ EnterPassword Parameters

| Parameter        | Description                                                                                                                                                                              |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b>     | Specifies a message to display in the dialog. This text is considered a static control. To display the default instructions for this dialog, pass a null string ("" ) in this parameter. |
| <b>szDefault</b> | Specifies the text that is initially displayed in the edit box.                                                                                                                          |
| <b>svResult</b>  | Returns the text that the end user enters in the edit box.                                                                                                                               |

## Return Values

**Table 13** ▪ EnterPassword Return Values

| Return Value              | Description                                       |
|---------------------------|---------------------------------------------------|
| <b>NEXT</b>               | Indicates that the user clicked the Next button.  |
| <b>BACK</b>               | Indicates that the user clicked the Back button.  |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the dialog could not be displayed. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

# ExistsDir

The **ExistsDir** function checks for the existence of a specified directory on the target system or the Internet.

## Syntax

```
ExistsDir ( szPath );
```

## Parameters

**Table 14** ▪ ExistsDir Parameters

| Parameters    | Description                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPath</b> | Specifies the fully qualified path of the directory to find on the target system, or the valid Uniform Resource Locator (URL) of the directory to find on the Internet. To check the validity of a URL, call Is(VAID_PATH, szURL). |

## Return Values

**Table 15** ▪ ExistsDir Return Values

| Return Value                     | Description                                                                                                                                                                                                                                                      |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EXISTS (0)</b>                | Indicates that the specified directory exists.                                                                                                                                                                                                                   |
| <b>NOTEXISTS (-1)</b>            | Indicates that the specified directory does not exist.                                                                                                                                                                                                           |
| <b>All other negative values</b> | Indicates that the function was unable to determine whether the specified directory exists. You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## ExistsDir Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ExistsDir function.
*
* AskPath is called to get a directory name from the user.
* Then, ExistsDir is called to determine whether the directory
* exists.
*
*-----*/

#define TITLE_TEXT "ExistsDir Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ExistsDir(HWND);

function ExFn_ExistsDir(hMSI)

```

```

    STRING svPath;
begin

    // Get the path to be created.
    AskPath ("Please enter a path:", "", svPath);

    // Check for the existence of the directory.
    if (ExistsDir (svPath) = EXISTS) then
        sprintfBox (INFORMATION, TITLE_TEXT, "%s already exists.", svPath);
    else
        sprintfBox (INFORMATION, TITLE_TEXT, "%s does not exist", svPath);
    endif;

end;

```

## ExistsDisk

The **ExistsDisk** function checks for the existence of a specified disk drive on the target system.

### Syntax

```
ExistsDisk ( szDisk );
```

### Parameters

**Table 16** ▪ ExistsDisk Parameters

| Parameter     | Description                             |
|---------------|-----------------------------------------|
| <b>szDisk</b> | Specifies the letter of the disk drive. |

### Return Values

**Table 17** ▪ ExistsDisk Return Values

| Return Value          | Description                                                             |
|-----------------------|-------------------------------------------------------------------------|
| <b>EXISTS (0)</b>     | Indicates that the specified drive exists on the target system.         |
| <b>NOTEXISTS (-1)</b> | Indicates that the specified drive does not exist on the target system. |

## ExistsDisk Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script

```

```

*
* Demonstrates the ExistsDisk function.
*
* AskText is called to get a disk drive name from the user.
* Then, ExistsDir is called to determine whether the drive
* exists.
*
/*-----*/

#define TITLE_TEXT "ExistsDisk Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_ExistsDisk(HWND);

function ExFn_ExistsDisk(hMSI)
    STRING svDrive;
begin

    if (AskText ("Enter the letter of a disk drive.", "C", svDrive) = NEXT) then
        // Check for the existence of the specified drive.
        if (ExistsDisk (svDrive) = EXISTS) then
            sprintfBox (INFORMATION, TITLE_TEXT, "Drive %s exists.", svDrive);
        else
            sprintfBox (INFORMATION, TITLE_TEXT, "Drive %s does not exist",
svDrive);
        endif;
    endif;

end;

```

## EzBatchAddPath

The **EzBatchAddPath** function modifies the default batch file by adding a path either to the search path in a PATH command or to the value assigned to an environment variable. Unless it is changed by a call to [BatchSetFileName](#), the default batch file is the Autoexec.bat file that was executed by the system during the boot sequence. To determine the fully qualified name of the default batch file, call [BatchGetFileName](#). To change the name of the batch file to be used by EzBatchAddPath, call BatchSetFileName.

**Caution** ▪ EzBatchAddPath does not make a backup copy of the file it modifies.

EzBatchAddPath can fail if the default batch file is hidden or read-only.

**Note** ▪ Do not mix Ez batch file functions and advanced batch file functions. After calling [BatchFileLoad](#) to load a batch file in memory, you cannot call any of the Ez batch file functions until you call [BatchFileSave](#) to save the file.

### Syntax

```
EzBatchAddPath ( szKey, szPath, szRefDir, nPosition );
```

## Parameters

**Table 18** ▪ EzBatchAddPath Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>     | Specifies the name of the environment variable to modify. For example, to modify the PATH statement, specify "PATH" here. If the specified environment variable is not found in the default file batch file, a complete SET statement is created for that environment variable and inserted into the file.                                                                                                                                                                                                                                                |
|                  |  <p><b>Caution</b> ▪ The EzBatchAddPath function does not support long file names. Call <a href="#">LongPathToShortPath</a> to convert the long path to its short path equivalent before passing it to EzBatchAddPath. For an explanation of long file names, see <a href="#">Long File Names</a>.</p>                                                                                                                                                                   |
| <b>szPath</b>    | Specifies the path to add to the current value of the environment variable. A delimiting semicolon is inserted to separate it from other paths in the search path.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szRefDir</b>  | Specifies the reference key (a path) relative to which you are adding the new path specified by szPath. If this is a null string (""), the directory is added to the beginning or end of the search path, depending on the value of nPosition. If the path specified by szRefDir is not found in the search path, the value of szKey is added to the end.                                                                                                                                                                                                 |
| <b>nPosition</b> | <p>Specifies where in the search path to add the new path. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>BEFORE</b>—The new path is inserted before the path specified by szRefDir. If szRefDir contains a null string (""), the directory is added to the front of the search path.</li> <li>● <b>AFTER</b>—The new path is inserted after the path specified by szRefDir. If szRefDir contains a null string (""), the directory is added to the end of the search path.</li> </ul> |

## Return Values

**Table 19** ▪ EzBatchAddPath Return Values

| Return Value  | Description                                                   |
|---------------|---------------------------------------------------------------|
| <b>0</b>      | EzBatchAddPath successfully added the path to the batch file. |
| <b>&lt; 0</b> | EzBatchAddPath was unable to add the path to the batch file.  |

## EzBatchAddPath Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the EzBatchAddPath function.
*
* First, BatchSetFileName is called to change the default batch
* file to EXAMPLE_BATCH. Then EzBatchAddPath is then called to
* add C:\WINDOWS to the beginning of the PATH statement. A
* second call to EzBatchAddPath adds C:\UTILS after the WINDOWS
* keyword in the PATH statement.
*
* Note: Before running this script, create a batch file
*      named ISExempl.bat and store it in the root of
*      drive C.
*
\*-----*/

#define EXAMPLE_BATCH "C:\\ISExempl.bat"
#define TITLE "EzBatchAddPath example"
#define MSG      "Successful.\n\n%s added to %s statement."

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzBatchAddPath(HWND);

function ExFn_EzBatchAddPath(hMSI)
    STRING szKey, szPath, szRefDir;
begin

    // Set the default batch file.
    BatchSetFileName (EXAMPLE_BATCH);

    // Set up parameters for next call to EzBatchAddPath.
    szKey      = "PATH";
    szPath     = "C:\\WINDOWS";
    szRefDir   = "";

    if (EzBatchAddPath (szKey, szPath, szRefDir, BEFORE) < 0) then
        // Report the error.
        MessageBox ("EzBatchAddPath failed.", SEVERE);
    else

        // Report success.
        sprintfBox (INFORMATION, TITLE, MSG, szPath, szKey);

        // Set up parameters for next call to EzBatchAddPath.
        szKey      = "PATH";
        szPath     = "C:\\UTILS";
        szRefDir   = "WINDOWS";

```

```

    if (EzBatchAddPath (szKey, szPath, szRefDir, AFTER) < 0) then
        // Report the error.
        MessageBox ("EzBatchAddPath failed.", SEVERE);
    else
        // Report success.
        sprintfBox (INFORMATION, TITLE, MSG, szPath, szKey);
    endif;

endif;

end;

```

## EzBatchAddString

The **EzBatchAddString** function adds a line of text to the default batch file; unless it is changed by a call to **BatchSetFileName**, the default batch file is the Autoexec.bat file that was executed by the system during the boot sequence. To determine the fully qualified name of the default batch file, call **BatchGetFileName**. To change the name of the batch file to be used by EzBatchAddPath, call BatchSetFileName.

---

**Caution** ▪ The EzBatchAddString function can fail if the default batch file is hidden or read-only.

EzBatchAddString does not make a backup copy of the file it modifies.

---

**Note** ▪ Do not mix Ez batch file functions and advanced batch file functions. After calling **BatchFileLoad** to load a batch file in memory, you cannot call any of the Ez batch file functions until you call **BatchFileSave** to save the file.

### Syntax

```
EzBatchAddString ( szLine, szRefKey, nOptions );
```

## Parameters

**Table 20** ▪ EzBatchAddString Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szLine</b>   | <p>Specifies the line of text to add to the file. Unless you specify NOSET in nOptions, this function assumes that szLine is an environment variable; the text "SET" is inserted at the front of the string before szLine is written to the default batch file.</p> <p></p> <p><b>Caution</b> ▪ The EzBatchAddString function does not support long file names. If you are using this function to add a line that contains a long path, call <a href="#">LongPathToShortPath</a> to convert the long path to its short path equivalent before adding it to the string to be placed in the batch file. For an explanation of long file names, see <a href="#">Long File Names</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>szRefKey</b> | <p>Specifies the reference key relative to which you want to add szLine in the default batch file. EzBatchAddString searches the default batch file for the reference key and places the contents of szLine before or after that line, depending on the value of nOptions.</p> <p></p> <p><b>Note</b> ▪ EzBatchAddString looks for the appropriate reference keyword in the parameter szRefKey. For example, the keyword for an environment variable is the name of the environment variable itself.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>nOptions</b> | <p>Specifies the option to use. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>BEFORE</b>—szLine is added before the line containing szRefKey. If szRefKey is a null string (""), szLine is added as the first line of the file.</li> <li>• <b>AFTER</b>—szLine is added after the line containing szRefKey. If szRefKey is a null string (""), szLine is added as the last line of the file.</li> <li>• <b>REPLACE</b>—szLine replaces an existing line in the file. If multiple lines with same key exist, EzBatchAddString replaces only the last line that contains the key.</li> <li>• <b>NOSET</b>—Specifies that the text "SET" should not be inserted at the front of the string in szLine.</li> <li>• <b>COMMAND</b>—Indicates that the reference key you are searching for is a DOS command or program name (not an environment variable).</li> </ul> <p>The NOSET and COMMAND constants can be combined with each other or the BEFORE, AFTER, or REPLACE constants using the logical OR operator. For example, when the reference key you are searching for is a DOS command or program name (not an environment variable), use the OR operator to combine the constant COMMAND with the constant AFTER, as shown below:</p> <pre>EzBatchAddString (szLine, szRefKey, AFTER   COMMAND);</pre> |

## Return Values

**Table 21** ▪ EzBatchAddString Return Values

| Return Value | Description                                                                      |
|--------------|----------------------------------------------------------------------------------|
| 0            | EzBatchAddString successfully added the text string to the specified batch file. |
| < 0          | EzBatchAddString was unable to add the text string.                              |

## EzBatchAddString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the EzBatchAddString function.
*
* This script performs four operations on a batch file:
*
* -- First, it adds a comment line at the top of the file.
*
* -- Next, it adds the line "SET TEMP=C:\EXAPP3", placing it
*   it after the PATH statement.
*
* -- Then, it adds the command "C:\EXAPP3\EXAPP.EXE", placing
*   it after the "SET TEMP=C:\EXAPP3" statement.
*
* -- Finally, it replaces the existing PATH statement with a
*   new PATH statement.
*
* Note: Before running this script, create a batch file
*       named ISExempl.bat and store it in the root of
*       drive C. For best effect, include a PATH statement
*       in that file.
*
\*-----*/

#define BATCH_FILE "C:\\ISExempl.bat"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzBatchAddString(HWND);

function ExFn_EzBatchAddString(hMSI)
    STRING szLine, szRefKey;
    NUMBER nOptions;
begin
```

```

// Set the default batch file.
BatchSetFileName (BATCH_FILE);

// Set up parameters for next call to EzBatchAddString.
szLine   = "rem This is the first line of the file.";
szRefKey  = "";
nOptions = BEFORE|NOSET;

// Add a comment line to the top of the batch file.
if (EzBatchAddString (szLine, szRefKey, nOptions) < 0) then
    MessageBox ("First call to EzBatchAddString failed.", SEVERE);
else
    MessageBox ("First call to EzBatchAddString successful.", INFORMATION);
endif;

// Set up parameters for next call to EzBatchAddString.
szLine   = "TEMP=C:\\EXAPP3";
szRefKey  = "PATH";
nOptions = AFTER;

// Add a line after the PATH statement.
if (EzBatchAddString (szLine, szRefKey, nOptions) < 0) then
    MessageBox ("Second call to EzBatchAddString failed.", SEVERE);
else
    MessageBox ("Second call to EzBatchAddString successful.", INFORMATION);
endif;

// Set up parameters for next call to EzBatchAddString.
szLine   = "C:\\EXAPP3\\EXAPP.EXE";
szRefKey  = "TEMP";
nOptions = AFTER|NOSET;

// Add a command line after the SET TEMP statement.
if (EzBatchAddString (szLine, szRefKey, nOptions) < 0) then
    MessageBox ("Third call to EzBatchAddString failed.", SEVERE);
else
    MessageBox ("Third call to EzBatchAddString successful.", INFORMATION);
endif;

// Set up parameters for next call to EzBatchAddString.
szLine   = "PATH=C:\\;C:\\Windows";
szRefKey  = "PATH";
nOptions = AFTER|NOSET|REPLACE|COMMAND;

// Replace the PATH statement.
if (EzBatchAddString (szLine, szRefKey, nOptions) < 0) then
    MessageBox ("Fourth call to EzBatchAddString failed.", SEVERE);
else
    MessageBox ("Fourth call to EzBatchAddString successful.", INFORMATION);
endif;

endprogram

```

# EzBatchReplace

The **EzBatchReplace** function replaces an existing line of text in the default batch file; unless it is changed by a call to **BatchSetFileName**, the default batch file is the Autoexec.bat file that was executed by the system during the boot sequence. To determine the fully qualified name of the default batch file, call **BatchGetFileName**. To change the name of the batch file to be used by EzBatchAddPath, call BatchSetFileName.

Some common keys in a batch file are PATH, COMSPEC, TEMP, Smartdrv.exe, Win.com, and Share.exe.

---

**Caution** ▪ The EzBatchReplace function may fail if the default batch file is hidden or read-only.

EzBatchReplace does not make a backup copy of the file it modifies.

---

**Note** ▪ Do not mix Ez batch file functions and advanced batch file functions. After calling **BatchFileLoad** to load a batch file in memory, you cannot call any of the Ez batch file functions until you call **BatchFileSave** to save the file.

## Syntax

```
EzBatchReplace ( szNewString );
```

## Parameters

**Table 22** ▪ EzBatchReplace Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szNewString</b> | Specifies the new string to insert in place of an existing line in the file. EzBatchReplace parses szNewString and determines the key of the string. It then searches the default batch file for a line that contains the same key. The function replaces the last line found with the same key.                                                                                                                                                                                    |
|                    |  <p><b>Caution</b> ▪ The EzBatchReplace function does not support long file names. If you are using this function to replace a line that contains a long path, call <a href="#">LongPathToShortPath</a> to convert the long path to its short path equivalent before replacing it in the string in the batch file. For an explanation of long file names, see <a href="#">Long File Names</a>.</p> |

## Return Values

**Table 23** ▪ EzBatchReplace Return Values

| Return Value  | Description                                            |
|---------------|--------------------------------------------------------|
| <b>0</b>      | EzBatchReplace successfully replaced the line of text. |
| <b>&lt; 0</b> | EzBatchReplace was unable to replace the line of text. |

## EzBatchReplace Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the EzBatchReplace function.
*
* EzBatchReplace is called to replace lines in a batch file.
*
* This script replaces three lines in the specified batch file.
* First, it replaces the SET COMSPEC command. Then it replaces
* the PATH statement. Finally, it replaces the command line
* that references SMARTDRV.EXE.
*
* Note: Before running this script, create a batch file
*       named ISExempl.bat and store it in the root of
*       drive C. For best effect, that file should include
```

```

*      the following lines:
*
*      SET COMSPEC=C:\COMMAND.COM
*      PATH C:\
*      SMARTDRV.EXE
*
\*-----*/

#define EXAMPLE_BAT "C:\\ISExempl.bat"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzBatchReplace(HWND);

function ExFn_EzBatchReplace(hMSI)
begin

    // Set the default batch file.
    BatchSetFileName (EXAMPLE_BAT);

    // Replace the SET COMSPEC statement.
    if (EzBatchReplace ("SET COMSPEC=C:\\DOS\\COMMAND.COM") < 0) then
        MessageBox ("First call to EzBatchReplace failed.", SEVERE);
    else
        MessageBox ("First call to EzBatchReplace succeeded.", INFORMATION);
    endif;

    // Replace the PATH command.
    if (EzBatchReplace ("PATH C:\\DOS;C:\\MYAPP") < 0) then
        MessageBox ("Second call to EzBatchReplace failed.", SEVERE);
    else
        MessageBox ("Second call to EzBatchReplace succeeded.", INFORMATION);
    endif;

    // Replace the SMARTDRIVE statement.
    if (EzBatchReplace ("SMARTDRV.EXE /P 1024 /C 512") < 0) then
        MessageBox ("Third call to EzBatchReplace failed.", SEVERE);
    else
        MessageBox ("Third call to EzBatchReplace succeeded.", INFORMATION);
    endif;

end;

```

## EzConfigAddDriver

The **EzConfigAddDriver** function adds a device driver statement to the default system configuration file. You can specify the position of the driver statement relative to another driver statement. For example, an application may require loading a device driver before or after the Windows Himem.sys driver.

Unless changed by a call to [ConfigSetFileName](#), the default system configuration file is the Config.sys file that was executed by the system during the boot sequence. To make another file the default system configuration file, call [ConfigSetFileName](#). To determine the fully qualified name of the default system configuration file, call [ConfigGetFileName](#).

---

**Note** ▪ Do not mix the Ez configuration file functions and the advanced configuration file functions. After calling [ConfigFileLoad](#), you cannot call any of the Ez configuration file functions until you call [ConfigFileSave](#) to save the file.

## Syntax

```
EzConfigAddDriver ( szDriver, szRefKey, nPosition );
```

## Parameters

**Table 24** ▪ EzConfigAddDriver Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDriver</b>  | Specifies the fully qualified name of the driver to add to the file. If the driver already exists in one or more places in the system configuration file, this function replaces only the last occurrence of the line containing the driver.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>szRefKey</b>  | Specifies the name of the device driver relative to which you are adding szDriver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>nPosition</b> | Indicates whether szDriver is to be added before or after the driver specified by szRefKey. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>BEFORE</b>—The statement is added before the line containing szRefKey. If szRefKey contains a null string (""), the driver is inserted as the first driver in the system configuration file.</li> <li>• <b>AFTER</b>—The statement is added after the line containing szRefKey. If szRefKey contains a null string (""), the driver is inserted as the last driver in the system configuration file.</li> </ul> |

## Return Values

**Table 25** ▪ EzConfigAddDriver Return Values

| Return Value  | Description                                                                   |
|---------------|-------------------------------------------------------------------------------|
| <b>0</b>      | EzConfigAddDriver successfully added the device driver statement to the file. |
| <b>&lt; 0</b> | EzConfigAddDriver was unable to add the driver statement.                     |

## EzConfigAddDriver Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the EzConfigAddDriver function.
*
* This example calls EzConfigAddDriver to add four statements
* to a configuration file.
*
* -- The first call to EzConfigAddDriver adds a new line of
* text after the last line.
```

```

*
* -- The second call adds a new line of text before the first
* line.
*
* -- The third call adds the driver C:\DRDOS\HIDOS.SYS after
* the key HIMEM.SYS
*
* -- The fourth call adds the driver EXAPP.SYS before the key
* HIMEM.SYS.
*
* Note: Before running this script, create a configuration file
* named ISExaml.sys in the root of drive C. For best
* effect, include the following line in that file:
*
*     DEVICE=C:\\Himem.sys
*
\*-----*/

#define EXAMPLE_SYS "C:\\ISExaml.sys"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzConfigAddDriver(HWND);

function ExFn_EzConfigAddDriver(hMSI)
    STRING szDriver, szRefKey;
begin

    // Set the default configuration file.
    ConfigSetFileName (EXAMPLE_SYS);

    // Set up parameters for next call to EzConfigAddDriver.
    szDriver = "C:\\NEW\\MYAPP.DRV";
    szRefKey = "";

    // Add a driver to the end of the configuration file.
    if (EzConfigAddDriver (szDriver, szRefKey, AFTER) < 0) then
        MessageBox ("First call to EzConfigAddDriver failed.", SEVERE);
    else
        MessageBox ("First call to EzConfigAddDriver successful.", INFORMATION);
    endif;

    // Set up parameters for next call to EzConfigAddDriver.
    szDriver = "C:\\SYSTEM\\DMDVR.BIN";
    szRefKey = "";

    // Add a driver to the top of the configuration file.
    if (EzConfigAddDriver (szDriver, szRefKey, BEFORE) < 0) then
        MessageBox ("Second call to EzConfigAddDriver failed.", SEVERE);
    else
        MessageBox ("Second call to EzConfigAddDriver successful.", INFORMATION);
    endif;

    // Set up parameters for next call to EzConfigAddDriver.
    szDriver = "C:\\DRDOS\\HIDOS.SYS";

```

```

szRefKey = "HIMEM.SYS";

// Add the "HIDOS.SYS" driver after the "HIMEM.SYS" key.
if (EzConfigAddDriver (szDriver, szRefKey, AFTER) < 0) then
    MessageBox ("Third call to EzConfigAddDriver failed.", SEVERE);
else
    MessageBox ("Third call to EzConfigAddDriver successful.", INFORMATION);
endif;

// Set up parameters for next call to EzConfigAddDriver.
szDriver = "EXAPP.SYS";
szRefKey = "HIMEM.SYS";

// Add the "EXAPP.SYS" driver before the "HIMEM.SYS" key.
if (EzConfigAddDriver (szDriver, szRefKey, BEFORE) < 0) then
    MessageBox ("Fourth call to EzConfigAddDriver failed.", SEVERE);
else
    MessageBox ("Fourth call to EzConfigAddDriver successful.", INFORMATION);
endif;

end;

```

## EzConfigAddString

The **EzConfigAddString** function adds a line of text to the default system configuration file. You can specify the position of the line you add in reference to another statement in the file.

Unless changed by a call to [ConfigSetFileName](#), the default system configuration file is the Config.sys file that was executed by the system during the boot sequence. To make another file the default system configuration file, call [ConfigSetFileName](#). To determine the fully qualified name of the default system configuration file, call [ConfigGetFileName](#).

---

**Note** ▪ Do not mix the Ez configuration file functions and the advanced configuration file functions. After calling [ConfigFileLoad](#), you cannot call any of the Ez configuration file functions until you call [ConfigFileSave](#) to save the file.

### Syntax

```
EzConfigAddString ( szLine, szRefKey, nOptions );
```

## Parameters

**Table 26** ▪ EzConfigAddString Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szLine</b>   | Specifies the line of text to add to the system configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>szRefKey</b> | Specifies the reference key relative to which you want to position szLine in the system configuration file. EzConfigAddString searches the system configuration file for the reference key and places the contents of the parameter szLine before or after the line containing the key, depending on which constants is passed in nOptions.                                                                                                                                                                                                                                                                                                                 |
| <b>nOptions</b> | Indicates whether the line specified by szLine is to be added before or after the line containing szRefKey. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>BEFORE</b>—The line specified by szLine is added before the line containing szRefKey. If szRefKey contains a null string (""), szLine is inserted as the first line of the system configuration file.</li> <li>• <b>AFTER</b>—The line specified by szLine is added after the line containing szRefKey. If szRefKey contains a null string (""), szLine is inserted as the last line of the system configuration file.</li> </ul> |

## Return Values

**Table 27** ▪ EzConfigAddString Return Values

| Return Value  | Description                                                                               |
|---------------|-------------------------------------------------------------------------------------------|
| <b>0</b>      | EzConfigAddString successfully added the string to the default system configuration file. |
| <b>&lt; 0</b> | EzConfigAddString was unable to add the text string.                                      |

## EzConfigAddString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the EzConfigAddString function.
*
* This example calls EzConfigAddString to add four lines to a
```

```

* configuration file.
*
* -- The first call adds a new line of text at the end of
* the file.
*
* -- The second call adds a new line of text at the top of
* the file.
*
* -- The third call adds the line FASTOPEN=512 after the key
* LASTDRIVE.
*
* -- The fourth call adds the line EXAPPHI=ON before the key
* EXAPPHI.SYS.
*
* Note: Before running this script, create a configuration
* file named ISExempl.sys and store it in the root of
* drive C. For best effect, that file should include
* the following lines:
*
* LASTDRIVE=F
* DEVICE=Exapphi.sys
*
\*-----*/

#define EXAMPLE_SYS "C:\\ISExempl.sys"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzConfigAddString(HWND);

function ExFn_EzConfigAddString(hMSI)
    STRING szLine, szRefKey;
begin

    // Set the default configuration file.
    ConfigSetFileName (EXAMPLE_SYS);

    // Set up parameters for next call to EzConfigAddString.
    szLine = "SHELL=C:\\COMMAND.COM /P /E:512";
    szRefKey = "";

    // Add a line to the end of the file.
    if (EzConfigAddString (szLine, szRefKey, AFTER) < 0) then
        MessageBox ("First call to EzConfigAddString failed.", SEVERE);
    else
        MessageBox ("First call to EzConfigAddString succeeded.", INFORMATION);
    endif;

    szLine = "DEVICE=C:\\System\\Dmdrvr.bin";
    szRefKey = "";

    // Add a line to the top of the file.
    if (EzConfigAddString (szLine, szRefKey, BEFORE) < 0) then
        MessageBox ("Second call to EzConfigAddString failed.", SEVERE);
    else

```

```

        MessageBox ("Second call to EzConfigAddString succeeded.", INFORMATION);
    endif;

    // Set up parameters for next call to EzConfigAddString.
    szLine    = "FASTOPEN=512";
    szRefKey  = "LASTDRIVE";

    // Add a line to the file after the key "LASTDRIVE".
    if (EzConfigAddString (szLine, szRefKey, AFTER) < 0) then
        MessageBox ("Third call to EzConfigAddString failed.", SEVERE);
    else
        MessageBox ("Third  call to EzConfigAddString succeeded.", INFORMATION);
    endif;

    // Set up parameters for next call to EzConfigAddString.
    szLine    = "EXAPPHI=ON";
    szRefKey  = "EXAPPHI.SYS";

    // Add a line to the file before the key "Exapphi.sys".
    if (EzConfigAddString (szLine, szRefKey, BEFORE) < 0) then
        MessageBox ("Fourth call to EzConfigAddString failed.", SEVERE);
    else
        MessageBox ("Fourth  call to EzConfigAddString succeeded.", INFORMATION);
    endif;

end;

```

## EzConfigGetValue

The **EzConfigGetValue** function retrieves the numeric value of a parameter, such as FILES or BUFFERS, from the default system configuration file.

Unless changed by a call to [ConfigSetFileName](#), the default system configuration file is the Config.sys file that was executed by the system during the boot sequence. To make another file the default system configuration file, call ConfigSetFileName. To determine the fully qualified name of the default system configuration file, call [ConfigGetFileName](#).

---

**Note** ▪ Do not mix the Ez configuration file functions and the advanced configuration file functions. After calling [ConfigFileLoad](#), you cannot call any of the Ez configuration file functions until you call [ConfigFileSave](#) to save the file.

### Syntax

```
EzConfigGetValue ( szRefKey, nvValue );
```

## Parameters

**Table 28** ▪ EzConfigGetValue Parameters

| Parameter       | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| <b>szRefKey</b> | Specifies the name of the parameter whose value is to be retrieved. |
| <b>nvValue</b>  | Returns the numeric value of the key specified by szRefKey.         |

## Return Values

**Table 29** ▪ EzConfigGetValue Return Values

| Return Value  | Description                                        |
|---------------|----------------------------------------------------|
| <b>0</b>      | EzConfigGetValue successfully retrieved the value. |
| <b>&lt; 0</b> | EzConfigGetValue was unable to retrieve the value. |

## EzConfigGetValue Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the EzConfigGetValue function.
 *
 * EzConfigGetValue is called to retrieve a value from a key in
 * the default configuration file. Unless changed by a call to
 * ConfigSetFileName, the default configuration file is the
 * Config.sys file that resides in the root of the boot drive.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzConfigGetValue(HWND);

function ExFn_EzConfigGetValue(hMSI)
    NUMBER nvValue;
begin

    // Retrieve the numeric value of the FILES key from the
    // default configuration file.
    if (EzConfigGetValue ("FILES", nvValue) < 0) then

```

```

        // Report the error.
        MessageBox ("EzConfigGetValue failed.", SEVERE);
    else
        // Display the value of the FILES key.
        sprintfBox (INFORMATION, "EzConfigGetValue Example",
            "FILES = %d", nvValue);
    endif;

end;

```

## EzConfigSetValue

The **EzConfigSetValue** function sets the value of a command in the default system configuration file.

Unless changed by a call to [ConfigSetFileName](#), the default system configuration file is the Config.sys file that was executed by the system during the boot sequence. To make another file the default system configuration file, call [ConfigSetFileName](#). To determine the fully qualified name of the default system configuration file, call [ConfigGetFileName](#).

---

**Note** - Do not mix the Ez configuration file functions and the advanced configuration file functions. After calling [ConfigFileLoad](#), you cannot call any of the Ez configuration file functions until you call [ConfigFileSave](#) to save the file.

### Syntax

```
EzConfigSetValue (szRefKey, nValue);
```

## Parameters

**Table 30** ▪ EzConfigSetValue Parameters

| Parameter       | Description                                                                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szRefKey</b> | Specifies the command whose value is to be changed or added in the default system configuration file. If the key does not exist in that file, it is added. |
| <b>nValue</b>   | Specifies the new value of the command specified by szRefKey.                                                                                              |

## Return Values

**Table 31** ▪ EzConfigSetValue Return Values

| Return Value  | Description                                   |
|---------------|-----------------------------------------------|
| <b>0</b>      | EzConfigSetValue successfully set the value.  |
| <b>&lt; 0</b> | EzConfigSetValue was unable to set the value. |

## EzConfigSetValue Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the EzConfigSetValue function.
*
* EzConfigSetValue is called to add or change the BUFFER and
* FILES commands in the default configuration file.
*
* Note: The first time you run this script, it will create a
*       file named ISExempl.sys in the root of drive C. You
*       may delete that file when you have finished analyzing
*       this script.
*
\*-----*/

#define EXAMPLE_SYS "C:\\ISExempl.sys"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzConfigSetValue(HWND);

function ExFn_EzConfigSetValue(hMSI)

```

```

    STRING szRefKey, szMsg;
    NUMBER nValue;
begin

    // Set the default configuration file.
    ConfigSetFileName (EXAMPLE_SYS);

    // Add or change the BUFFERS command.
    if (EzConfigSetValue ("BUFFERS", 30) < 0) then
        MessageBox ("Unable to set Buffers in " + EXAMPLE_SYS + ".", SEVERE);
    else
        MessageBox ("Buffers set to 30 in " + EXAMPLE_SYS + ".", INFORMATION);
    endif;

    // Add or change the FILES command.
    if (EzConfigSetValue ("FILES", 30) < 0) then
        MessageBox ("Unable to set Files in " + EXAMPLE_SYS + ".", SEVERE);
    else
        MessageBox ("Files set to 30 in " + EXAMPLE_SYS + ".", INFORMATION);
    endif;

end;

```

## EzDefineDialog

The **EzDefineDialog** function defines a custom dialog.

---

**Note** ▪ This function does not display the custom dialog. To display a custom dialog, call [WaitOnDialog](#).

### Syntax

```
EzDefineDialog ( szDialogName, szDLLName, szDialogID, nDialogID );
```

## Parameters

**Table 32** ▪ EzDefineDialog Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDialogName</b> | <p>Specifies the name to associate with the dialog identified by szDialogID or nDialogID. To process this dialog, use this name in subsequent calls to custom dialog functions.</p> <p>Note that the dialog's name is case-sensitive; you must use it exactly as you have specified it in this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szDLLName</b>    | <p>Specifies the name of the .dll file that contains the dialog resource. If this name is not qualified (that is, if you do not specify the drive and path with the file name), the InstallScript engine searches for the .dll file in the Windows folder. If it is not found there, the InstallScript engine searches the folders that are specified in the search path. When the dialog is located in _isuser.dll, you can specify a null string (""), the InstallScript engine automatically checks _isuser.dll if this parameter is specified as a null string ("").</p> <div>  <p><b>Note</b> ▪ When you use a .dll file other than _isres.dll or _isuser.dll, you must call <a href="#">UseDLL</a> to load the .dll file before calling <b>EzDefineDialog</b>. To unload the .dll file from memory, call <a href="#">UnUseDLL</a> after calling <a href="#">ReleaseDialog</a>.</p> </div>                                                                                                                                                                                                                                        |
| <b>szDialogID</b>   | <p>Specifies the dialog's resource ID if you use a string rather than a number to identify the resource. If this parameter is a null string (""), nDialogID is used to identify the dialog resources. It is recommended that you use nDialogID rather than szDialogID to identify the dialog resource.</p> <div>  <p><b>Note</b> ▪ If you created the dialog in the Dialogs view, the dialog is created with a string ID; therefore, you must specify this name as the szDialogID parameter to define the dialog.</p> <p>If you override an existing dialog in the Dialogs view, the dialog has a numeric ID, and you must specify the ID in the nDialogID parameter.</p> <p>If you want to use numeric IDs in all cases—which is what is recommended—you must edit the dialog in the Dialogs view to change the ISResourceID property of the created dialog to the desired Dialog ID instead of 0. Note that if you do this, the dialog name is no longer used when the dialog is created; it is used only in the Dialogs view in InstallShield to identify the dialog. The dialog is built with the correct numeric ID.</p> </div> |
| <b>nDialogID</b>    | <p>Specifies the dialog's resource ID if you use a number rather than a string to identify the resource. This parameter is used only when szDialogID is a null string (""). It is recommended that you use nDialogID rather than szDialogID to identify the dialog resource.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Return Values

**Table 33** ▪ EzDefineDialog Return Values

| Return Value                       | Description                                                                                                                                                  |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                           | <b>EzDefineDialog</b> successfully defined the dialog.                                                                                                       |
| <b>DLG_ERR_ALREADY_EXISTS (-3)</b> | Indicates that you are trying to define a dialog that has already been defined in the installation script. You cannot define two dialogs with the same name. |
| <b>DLG_ERR (-1)</b>                | Indicates an unspecified error condition.                                                                                                                    |

## EzDefineDialog Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the EzDefineDialog function.
*
* This script opens a simple custom dialog that displays
* a bitmap. The dialog can be closed with any of three
* buttons: Back, Next, or Cancel.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdBitmap. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
* In order to use this custom dialog, the script first defines
* it by calling EzDefineDialog. It then displays the dialog
* and gets dialog events by calling WaitOnDialog. When an
* event ends dialog processing, EndDialog is called to close
* the dialog. Then the dialog is released from memory by
* a call to ReleaseDialog.
*
\*-----*/

// Dialog and control IDs.
#define RES_DIALOG_ID      12027 // ID of dialog itself
#define RES_PBUT_NEXT      1     // ID of Next button
#define RES_PBUT_CANCEL    9     // ID of Cancel button
#define RES_PBUT_BACK      12    // ID of Back button

```

```

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzDefineDialog(HWND);

function ExFn_EzDefineDialog(hMSI)
    STRING  szDialogName, szDLLName, szDialog;
    NUMBER  nDialog, nResult, nCmdValue;
    BOOL     bDone;
    HWND     hInstance, hwndParent, hwndDlg;
begin

    // Specify a name to identify the custom dialog in this installation.
    szDialogName = "CustomDialog";

    // Define the dialog. Pass a null string in the second parameter
    // to get the dialog from _isuser.dll or _isres.dll. Pass a null
    // string in the third parameter because the dialog is identified
    // by its ID in the fourth parameter.
    nResult = EzDefineDialog (szDialogName, "", "", RES_DIALOG_ID);

    if (nResult < 0) then
        // Report an error; then terminate.
        MessageBox ("Error in defining dialog", SEVERE);
        abort;
    endif;

    // Initialize the indicator used to control the while loop.
    bDone = FALSE;

    // Loop until done.
    repeat

        // Display the dialog and return the next dialog event.
        nCmdValue = WaitOnDialog(szDialogName);

        // Respond to the event.
        switch (nCmdValue)
        case DLG_CLOSE:
            // The user clicked the window's Close button.
            Do (EXIT);
        case DLG_ERR:
            MessageBox ("Unable to display dialog. Setup canceled.", SEVERE);
            abort;
        case DLG_INIT:
            // Initialize the back, next, and cancel button enable/disable states
            // for this dialog and replace %P, %VS, %VI with
            // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
            // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
            hwndDlg = CmdGetHwndDlg(szDialogName);
            SdGeneralInit(szDialogName, hwndDlg, 0, "");
        case RES_PBUT_CANCEL:
            // The user clicked the Cancel button.
            Do (EXIT);
        case RES_PBUT_NEXT:
            bDone = TRUE;

```

```

        case RES_PBUT_BACK:
            bDone = TRUE;
            if (SdIsStdButton( nCmdValue ) && SdDoStdButton( nCmdValue )) then
                bDone = TRUE;
            endif;
        endswitch;

    until bDone;

    // Close the dialog.
    EndDialog (szDialogName);

    // Free the dialog from memory.
    ReleaseDialog (szDialogName);

end;

```

## FeatureAddCost

**Project** ▪ This information applies to InstallScript projects.

The **FeatureAddCost** function specifies that the feature includes additional installation operations that should be accounted for when updating the progress bar during the installation. Specifically, the **FeatureAddCost** function adds the value of `nCost` to the specified feature. This function can be called anytime before calling **StatusUpdate**, but it should typically be used before displaying a feature dialog so that the dialog shows the intended size for the feature to be installed.

**Important** ▪ The **FeatureAddCost** function is supported only for file media. Use **FeatureGetData** or **FeatureSetData** to set the size of script-created features.

**Note** ▪ The information specified in this function is not remembered in subsequent installations. This function should be called each time that the feature is being installed, including during repair or maintenance mode. Also, the setup engine has no way to determine whether the specified cost is for a single file or multiple files. Therefore, it does not attempt to adjust the specified size based on the cluster size of the target drive. Thus, you should use the **GetAndAddFileCost**, **CalculateAndAddFileCost**, or **GetAndAddAllFilesCost** functions to determine the cost of the file, taking into account cluster size, before calling this function.

### Syntax

```
FeatureAddCost ( szMediaSource, szFeature, szTarget, nCostHigh, nCostLow );
```

## Parameters

**Table 34** • FeatureAddCost Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMediaSource</b> | The media source, typically MEDIA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>szFeature</b>     | Specifies the feature to add this cost to. Note that a specific feature in the media must be specified as installation cost is calculated by feature. Cost cannot be specified for the entire media.                                                                                                                                                                                                                                                                                                                                                    |
| <b>szTarget</b>      | Specifies the target directory for the cost specified by nCost. This value is used when determining which volume or drive this cost applies to and when displaying the size required for the feature in the feature dialog. Currently, only a single szTarget variable for custom cost is supported for each feature. If you call this function multiple times for the same feature, szTarget variable should be the same each time. Otherwise, the value specified during the last call is used for the target of all additional cost for the feature. |
| <b>nCostHigh</b>     | Specifies the upper 31 bits of the additional cost to be added to the feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>nCostLow</b>      | Specifies the lower 31 bits of the additional cost to be added to the feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 35** • FeatureAddCost Return Values

| Return Value              | Description                                              |
|---------------------------|----------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function successfully added the cost. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was unable to add the cost.  |

# FeatureAddItem

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureAddItem** function adds a feature to a script-created feature set. If a script-created feature set with the name specified by szFeatureSet does not already exist, this function creates it.

Call **FeatureAddItem** once for each feature you want to add to a given script-created feature set. You can create multiple script-created feature sets, each with a unique name (szFeatureSet parameter).

---

**Caution** ▪ *This function cannot be used with file media libraries.*

## Syntax

```
FeatureAddItem ( szFeatureSet, szFeature, nDataSize, bSelected );
```

## Parameters

**Table 36** • FeatureAddItem Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSet</b> | Specifies the name of the script-created feature set to which an item will be added. If the script-created feature set does not exist, <b>FeatureAddItem</b> creates it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>szFeature</b>    | Specifies the name of the feature to be added. Do not use a null string (""). To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>nDataSize</b>    | Specifies the size in bytes of the data the feature represents. If the feature is a series of files, this parameter specifies the total uncompressed size of all the files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>bSelected</b>    | <p>Specifies the default selection setting of the feature. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Indicates that the feature is selected by default. If TRUE is passed to select a subfeature whose parent feature is not selected, the subfeature is not selected—despite passing TRUE in the bSelected parameter.</li> <li>● <b>FALSE</b>—Indicates that the feature is not selected by default.</li> </ul>  <p><b>Note</b> • Default selection settings are cleared when the user selects a feature or subfeature displayed in a dialog. If the user clears a selected feature, all of its subfeatures are cleared. If the user clears all of a feature's subfeatures, the feature's selection setting is cleared.</p> |

## Return Values

**Table 37** • FeatureAddItem Return Values

| Return Value  | Description                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | <b>FeatureAddItem</b> successfully added the item to the feature or subfeature to the script-created feature set.                                                                |
| <b>&lt; 0</b> | <b>FeatureAddItem</b> was unable to add the item to the feature or subfeature to the script-created feature set. For additional information, call <a href="#">FeatureError</a> . |

## Additional Information

- To display a single level of features to the end user for selection, use [FeatureDialog](#), [SdFeatureDialog](#), or [SdFeatureDialogAdv](#).

- To display features and their subfeatures, use [SdFeatureDialog2](#), [SdFeatureMult](#), or [SdFeatureTree](#).
- You can use **FeatureAddItem** and script-created feature sets to allow users to select from options other than file media feature options:
  1. Call **FeatureAddItem** to create a script-created feature set containing the options you want.
  2. To display those options for selection, call **SdAskOptions** or **SdAskOptionsList** with the script-created feature set name in the parameter `szFeature`.
  3. To determine which options were selected, call **FeatureIsItemSelected**.

## FeatureAddItem Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureAddItem function.
 *
 * In this script, FeatureAddItem is called to create a
 * script-created feature set consisting of drives attached
 * to the target system. These features are displayed in an
 * SdAskOptionsList dialog so that the end user can select
 * from among the drives.
 *
 \*-----*/

LIST listDrives, listFeatures;
STRING szSaveMEDIAValue, svDrive;
LONG nResult;
BOOL bSelected;

#include "ifx.h"

function OnBegin()
begin

    // Create the list to store drive names.
    listDrives = ListCreate(STRINGLIST);

    // Add all fixed drives to the list.
    GetValidDrivesList(listDrives, FIXED_DRIVE, -1);

    // Save the value of the system variable MEDIA so it can
    // be restored for later calls to transfer data.
    szSaveMEDIAValue = MEDIA;

    // Specify a name for the script-created feature set.
    MEDIA = "Drives";

    // Put the drive names into the script-created feature set.
    nResult = ListGetFirstString(listDrives, svDrive);
    while (nResult != END_OF_LIST)
        FeatureAddItem(MEDIA, svDrive, 0, FALSE);
        nResult = ListGetNextString(listDrives, svDrive);

```

```

endwhile;

// Display the list of drives. Let user select one drive.
SdAskOptionsList("Select a Drive" ,
"Select one of the drives attached to your system." ,
"" , EXCLUSIVE);

// Find the selected drive in the list.
bSelected = FALSE;
nResult = ListGetFirstString(listDrives, svDrive);
bSelected = ComponentIsItemSelected (MEDIA , svDrive);
while ((nResult != END_OF_LIST) && !bSelected);
    nResult = ListGetNextString(listDrives, svDrive);
    bSelected = ComponentIsItemSelected (MEDIA , svDrive);
endwhile;

// Release the list from memory.
ListDestroy (listDrives);
if bSelected then
    MessageBox("You selected drive " + svDrive + ".", INFORMATION);
endif;

// Restore MEDIA to its previous value for file transfer.
MEDIA = szSaveMEDIAValue;

end;

```

## FeatureAddUninstallCost

**Project** - This information applies to InstallScript projects.

The **FeatureAddUninstallCost** function specifies that the feature includes additional uninstallation operations that must be accounted for when updating the progress bar during uninstallation. You do not have to call this function for operations that are included in the uninstallation log file. This includes operations that are handled by the **XCOPYFile** function that may or may not have had to call the **FeatureAddCost** function to update the progress bar during the installation. This function is only needed for operations that were carried out by functionality other than the InstallScript engine. This function can be called anytime before calling **StatusUpdate** and can be called multiple times.

### Syntax

```
FeatureAddUninstallCost ( szMediaSource, szFeature, nOps, nOpType);
```

## Parameters

**Table 38** ▪ FeatureAddUninstallCost Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMediaSource</b> | The media source, typically MEDIA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>szFeature</b>     | Specifies the feature to add this cost to. Note that a specific feature in the media must be specified. Uninstallation cost is calculated by feature. Cost cannot be specified for the entire media.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>nOps</b>          | The number of operations to be added.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>nOpType</b>       | <p>Indicates the type of operation. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FEATURE_OPCOST_UNINSTALL_FILE</b>—Specifies the operation as uninstalling a file. You can also specify this constant using the value 4096. This enables you to experiment with different sizes to determine what size to use for your custom operation.</li> <li>● <b>FEATURE_OPCOST_UNINSTALL_REGORINI</b>—Specifies the operation as uninstalling a registry file. You can also specify this constant using the value 2048. This enables you to experiment with different sizes to determine what size to use for your custom operation.</li> <li>● <b>FEATURE_OPCOST_UNINSTALL_UNREGFILE</b>—Specifies the operation as unregistering a file. You can also specify this constant using the value 16384. This enables you to experiment with different sizes to determine what size to use for your custom operation.</li> </ul> <p> <b>Note</b> ▪ You can also pass a numeric value in this parameter to indicate an operation of a specific cost. You may need to experiment with different values to determine the appropriate value for a specified custom operation. Note that the total uninstall cost added is nOps multiplied by nOpType.</p> |

## Return Values

**Table 39** ▪ FeatureAddUninstallCost Return Values

| Return Value              | Description                                              |
|---------------------------|----------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function successfully added the cost. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was unable to add the cost.  |

# FeatureCompareSizeRequired

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureCompareSizeRequired** function determines whether the target folder contains enough free space for the selected features specified by `szFeatureSource`, which must be a file media. If the target folder does not have sufficient free space, the fully qualified folder name is returned in `svTarget` and the amount of required free space is returned in `nvSize`.

If your setup specifies a destination folder for a feature in a file library at run time, it must do so by calling **FeatureSetTarget** before checking for free space with **FeatureCompareSizeRequired**.

---

**Note** ▪ This function cannot be used with script-created feature sets.

## Syntax

```
FeatureCompareSizeRequired ( szFeatureSource, svTarget, nvSize );
```

## Parameters

**Table 40** • FeatureCompareSizeRequired Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | You must pass the system variable <b>MEDIA</b> in this parameter. No other value is valid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>svTarget</b>        | <p>Returns a null string ("") if there is sufficient free space available on the target drive. Returns the target path if there is <i>not</i> sufficient free space on the target drive.</p> <p></p> <p><b>Note</b> - The parameter <b>svTarget</b> is used only to return a folder name. You cannot use the parameter to specify a destination folder.</p> <p><b>FeatureCompareSizeRequired</b> checks the drive that is indicated by the destination folder that you specified for each component in the Components view. If <b>szFeatureSource</b> is a file media with features to be installed in the General Application Destination, you must assign a destination path to <b>TARGETDIR</b> (in InstallScript installations) or <b>INSTALLDIR</b> (in InstallScript MSI installations) before calling <b>FeatureCompareSizeRequired</b>. You can obtain a destination path from an end user by calling <b>AskDestPath</b> or a feature dialog.</p> |
| <b>nvSize</b>          | Returns 0 if there is sufficient free space available on the target drive. Returns the size (in bytes) required if there is <i>not</i> sufficient free space on the target drive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 41** • FeatureCompareSizeRequired Return Values

| Return Value  | Description                                                                             |
|---------------|-----------------------------------------------------------------------------------------|
| <b>0</b>      | FeatureCompareSizeRequired was successful.                                              |
| <b>&lt; 0</b> | FeatureCompareSizeRequired failed. Call <b>FeatureError</b> for additional information. |

## FeatureCompareSizeRequired Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureAddItem, FeatureSetData,
 * FeatureCompareSizeRequired, and SdFeatureMult functions.
```

```

*
* Notes: DESTDIR must reference a drive with very little space
*        available, such as a floppy drive. Remember to put a
*        diskette into the floppy drive before running this
*        script.
*

## FeatureConfigureFeaturesFromSuite

**Project** ▪ This information applies to InstallScript projects.

**Note** ▪ This function is available for InstallScript installations that may be included as InstallScript packages in an Advanced UI or Suite/Advanced UI installation. It is also available in an InstallScript installation that is included in an Advanced UI or Suite/Advanced UI installation as an executable package. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

*In addition, this function is available in an InstallScript installation that is launched directly (that is, not from an Advanced UI or Suite/Advanced UI installation).*

The **FeatureConfigureFeaturesFromSuite** function sets feature states for the current InstallScript package that is running in an Advanced UI or Suite/Advanced UI installation based on the values of the Advanced UI or Suite/Advanced UI properties **ISFeatureInstall** and **ISFeatureRemove**. The function is called by the default code in the **OnSuiteInstallBefore** event (for an install operation) and **OnSuiteMaintBefore** event (for a modify operation).

The **FeatureConfigureFeaturesFromSuite** function also lets you set the feature state for InstallScript installations that are launched as an executable package in an Advanced UI or Suite/Advanced UI installation, or that are launched directly outside an Advanced UI or Suite/Advanced UI installation. In these cases, the function sets feature states based on the **ISFeatureInstall** and **ISFeatureRemove** key-value pairs.

## Syntax

`FeatureConfigureFeaturesFromSuite (string szCommandLine);`

## Parameters

**Table 42** • FeatureConfigureFeaturesFromSuite Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szCommandLine</b> | <p>Specify the command line that you want to use to set <code>ISFeatureInstall</code>, <code>ISFeatureRemove</code>, or both. Set these to a comma-delimited list of feature names as follows:</p> <p><code>ISFeatureInstall=Feature1,Feature2 ISFeatureRemove=Feature3</code></p> <p>In the above example, Feature1 and Feature2 are selected to be installed; Feature3 is selected to be removed, if it is present.</p> <p>If any features are used in the values of both properties, the features that are set for the <code>ISFeatureRemove</code> property supersede the <code>ISFeatureInstall</code> property.</p> <p>If <code>szCommandLine</code> does not set either property or both properties, the call to <b>FeatureConfigureFeaturesFromSuite</b> has no effect.</p> <p>To learn how to refer to top-level features and subfeatures for <code>ISFeatureInstall</code> and <code>ISFeatureRemove</code>, see <a href="#">Specifying Features and Subfeatures in Function Calls</a>.</p> |

## Return Values

This function has no return values.

# FeatureDialog

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureDialog** function displays a dialog that enables the end user to select one or more items from a list of features in the installation. The end user can also select a destination location.

When the end user clicks the Browse button, the Choose Folder dialog, which displays a list of existing folders, opens. The end user can select an existing folder from the list or enter a new folder name in the Path field.

**FeatureDialog** returns the name of the specified folder in `svDir`. If the user specifies a folder that does not currently exist, the installation creates the folder.

---

**Caution** ▪ If your installation does not use a setup type dialog, you must call **FeatureSetupTypeSet** to specify a setup type that has been defined in the Setup Types view in InstallShield before calling **FeatureDialog**.

## Syntax

```
FeatureDialog ( szTitle, szMsg, svDir, szFeature );
```

## Parameters

**Table 43** ▪ FeatureDialog Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the dialog title. To display the default title (“Select Features”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>szMsg</b>     | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>svDir</b>     | <p>Specifies the default destination location variable. Returns the folder selected by the end user. The location returned in svDir does not affect file transfer unless you assign it to TARGETDIR (in InstallScript installations) or INSTALLDIR (in InstallScript MSI installations).</p> <p>If the default folder specified by svDir does not already exist on the end user’s system, it will not be created unless the end user clicks the Browse button and follows the steps to create it from the Choose Folder dialog. Therefore, whenever you specify a default folder, you must call <a href="#">ExistsDir</a> when FeatureDialog returns in order to determine whether that folder exists. If it does not exist, call <a href="#">CreateDir</a> to create it on the end user’s system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>szFeature</b> | <p>Specifies the feature whose subfeatures are displayed for selection. Pass a null string (“”) in this parameter to display all top-level features. To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a>.</p> <p>FeatureDialog searches for the requested features in the script-created feature set specified by the system variable <a href="#">MEDIA</a>.</p> <div data-bbox="631 1226 669 1272" data-label="Image"> </div> <p><b>Note</b> ▪ If necessary, feature names are truncated to allow the display of the largest possible feature size. The space required to display the size depends on the maximum feature size (2 GB), the feature size options currently in use, and the font used to display feature information in the dialog. Feature size options are set with the <a href="#">DialogSetInfo</a> function.</p> <p>When the space required to display the maximum possible size has been determined, all feature names are truncated automatically—if necessary—to fit the remaining space. This ensures that feature names will not overlap feature sizes.</p> <p>Note that the name of a feature that requires less space to display its size (or that is not selected) may still be truncated under this method. To maximize performance and ensure that complete feature names are displayed, make feature names or display names smaller than the space available in the dialog.</p> |

## Return Values

**Table 44** • FeatureDialog Parameters

| Return Value     | Description                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button.                                                      |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button.                                                      |
| <b>&lt; 0</b>    | Unable to display the FeatureDialog dialog. Call <a href="#">FeatureError</a> for additional information. |

## Additional Information

The Choose Folder dialog indicates the amount of disk space that each feature occupies. A feature's size is displayed as 0 if it is not selected. Once it has been selected, its actual size is displayed.

## FeatureDialog Example

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureDialog function.
 *
 * This example script displays a dialog that displays a list
 * of features in the setup that the user can install and the
 * amount of space that each feature occupies.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features
 *           and/or subfeatures with components containing
 *           files.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

// Include iswi.h for Windows Installer API function prototypes and constants,
// and to declare code for the OnBegin and OnEnd events.
#include "iswi.h"

// The keyword export identifies MyFunction() as an entry-point function.
// The argument it accepts must be a handle to the Installer database.
```

```

export prototype MyFunction(HWND);

// To Do: Declare global variables, define constants, and prototype user-
//         defined and DLL functions here.

function MyFunction(hMSI)

    STRING szTitle, szMsg, svDir;

begin

    svDir    = INSTALLDIR;
    szTitle  = "Select Features";
    szMsg    = "Select the features you want to install on your computer.";

    // Display available features.
    FeatureDialog (szTitle, szMsg, svDir, "");

end;

```

## FeatureError

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

**FeatureError** does not return error information for unsupported functions. For example, ComponentInitialize, ComponentUpdate, and ComponentValidate are not supported as feature functions. FeatureError does not work for these functions.

The FeatureError function obtains additional error information when a feature function returns a value less than zero. The following code fragment shows a typical implementation of FeatureError:

```

nResult = FeatureGetData (MEDIA, svFeature, FEATURE_FIELD_SELECTED, nvResult,
                          svResult);

if(nResult < 0) then
    FeatureError(svFeatureSource, svFeature, svComponent, svFile, nvError);

    sprintfBox (INFORMATION, "FeatureGetData Error Information",
                "FeatureGetData had the following error:\n\n" +
                "Media Name: %s\nFeature: %s\nComponent: %s\n" +
                "File: %s\nError Number: %ld"
                svFeatureSource, svFeature, svComponent, svFile, nvError);

endif;

```

The FeatureError function should be called only after another feature function returns a value less than zero. FeatureError might return invalid error codes if called when another feature function has not returned a value that is less than zero.

**Note** ▪ *FeatureError* returns information for all parameters (media name, feature name, component name, file name, and error code) only for **script-created feature sets**. For features in the file media (MEDIA), *FeatureError* returns only the error code.

## Syntax

```
FeatureError ( svFeatureSource, svFeature, svComponent, svFile, nvError );
```

## Parameters

**Table 45** ▪ FeatureError Parameters

| Parameter              | Description                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svFeatureSource</b> | Returns the media name of the script-created feature set if relevant to the error indicated by nvError.                                                 |
| <b>svFeature</b>       | Returns the name of the feature if relevant to the error indicated by nvError.                                                                          |
| <b>svComponent</b>     | Returns the name of the component if relevant to the error indicated by nvError.                                                                        |
| <b>svFile</b>          | Returns the name of the file if relevant to the error indicated by nvError.                                                                             |
| <b>nvError</b>         | Returns a code that identifies the type of error that occurred in a previous call to a feature-related function. These error codes are described below. |

## Error Codes

The following table describes the error codes returned by *FeatureError*.

**Note** ▪ *After correcting errors involving the media, you must rebuild the project.*

**Table 46** ▪ FeatureError Error Codes

| Code        | Description                       | Cause                                                                                |
|-------------|-----------------------------------|--------------------------------------------------------------------------------------|
| <b>-101</b> | Cannot add feature.               | <b>FeatureAddItem</b> was unable to add a feature to the script-created feature set. |
| <b>-102</b> | Specified feature already exists. | <b>FeatureAddItem</b> was called twice with the same media name and feature name.    |

**Table 46** • FeatureError Error Codes (cont.)

| Code        | Description                                                       | Cause                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-103</b> | Specified feature cannot be selected or deselected.               | <b>FeatureSelectItem</b> was used to select or deselect a feature that is required by a currently selected feature. Deselect the dependent feature (that requires the other feature) before attempting to select or deselect the required feature.                                                                  |
| <b>-105</b> | Specified feature cannot be found in the media.                   | An attempt was made to access a feature that does not exist. This error occurs when a feature name is specified incorrectly in a feature function call. Feature names must be specified exactly as they appear in the Setup Design view or in the call to <b>FeatureAddItem</b> . Feature names are case-sensitive. |
| <b>-108</b> | Out of disk space.                                                | The target disk or directory has insufficient free space, the disk space cannot be determined because TARGETDIR (in an InstallScript installation) or INSTALLDIR (in an InstallScript MSI installation) is invalid, or a script-defined folder of a feature has not been set.                                       |
| <b>-118</b> | Attempted operation not allowed with script-created feature sets. | A script-created feature set name was passed to a feature function that operates only on file media.                                                                                                                                                                                                                |
| <b>-125</b> | The list specified in the feature function is not valid.          | When calling <b>FeatureListItems</b> , verify that the list you are passing to the function is valid.                                                                                                                                                                                                               |
| <b>-126</b> | Attempted operation not allowed with file media library.          | A file media name was passed to a feature function (for example, <b>FeatureAddItem</b> ), that operates only on script-created feature sets.                                                                                                                                                                        |
