| <b>-132</b> | The specified media cannot be found.                              | The media has been declared, but it not associated with any features. Make sure that script-created features are associated with the media.                                                                                                                                                                         |
| <b>-136</b> | Unable to allocate memory.                                        | Insufficient memory is available to the setup. Display a message to the end user to close all other applications or to cancel the setup, reboot the system, and restart the setup.                                                                                                                                  |
| <b>-137</b> | Specified option is not valid.                                    | An invalid option has been specified for a feature function—for example, specifying only a component when both a component and file name are required.                                                                                                                                                              |
| <b>-147</b> | Invalid value passed to a feature-related function.               | One of the values passed to a feature function is invalid. This error can be caused, for example, by passing an empty string in the second parameter of <b>FeatureAddItem</b> .                                                                                                                                     |

## Return Values

**Table 47** ▪ FeatureError Return Values

| Return Value | Description                  |
|--------------|------------------------------|
| 0            | FeatureError was successful. |
| < 0          | FeatureError failed.         |

## FeatureError Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureError function.
 *
 * This example script demonstrates a function that adds a feature
 * to a script-created feature set.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features and/or
 *           subfeatures with components containing files.
 *
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

// Include iswi.h for Windows Installer API function prototypes and constants,
// and to declare code for the OnBegin and OnEnd events.
#include "iswi.h"

// The keyword export identifies MyFunction() as an entry-point function.
// The argument it accepts must be a handle to the Installer database.
export prototype MyFunction(HWND);
prototype HandleMoveDataError(number);

// To Do: Declare global variables, define constants, and prototype user-
//         defined and DLL functions here.

function MyFunction(hMSI)

    STRING  szTitle, szMsg;
    NUMBER  listID, nResult;

begin

    szTitle = "List MEDIA Features";
    szMsg   = "MEDIA contains the following top-level features:";

    // Initialize the string list.
    listID = ListCreate (STRINGLIST);

```

```

    // Create a list of top-level features in the specified media.
    nResult = FeatureListItems (MEDIA, "", listID);

    // Call the error handler function.
    HandleMoveDataError (nResult);

    // Display a list of top-level features.
    SdShowInfoList (szTitle, szMsg, listID);

end;

function HandleMoveDataError(nResult)

    STRING szErrMsg, svFeature , svComponent , svFile;

begin

    svFeature = "";
    svComponent = "";
    svFile = "";

    // In cases where FeatureListItems returns a value not equal to zero, display an
    // error message.
    switch (nResult)
        case 0:
            return 0;
        default:
            FeatureError (MEDIA , svFeature , svComponent , svFile , nResult);
            szErrMsg = "An error occurred during the process: %d" + "\n\n" +
                "Feature: " + svFeature + "\n" +
                "Component: " + svComponent + "\n" +
                "File: " + svFile;
            SprintfBox (SEVERE, "", szErrMsg, nResult);
            return nResult;
    endswitch;

end;

```

## FeatureErrorInfo

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureErrorInfo** function, which is called in the default code for the OnComponentError event handler, returns information about a file transfer error that does not generate any error event other than FeatureError—for example, FileLocked or SelfRegistrationError.

**Note** ▪ This function returns information only about file transfer errors. For information about errors from script-created features, call [FeatureError](#).

## Syntax

```
FeatureErrorInfo ( );
```

## Parameters

None

## Return Values

A reference that can be assigned to a variable of type OBJECT by using the set keyword. Upon assignment, that variable (oErrorInfo in the following example) has the following properties:

**Table 48** ▪ FeatureErrorInfo Return Values

| Property                              | Description                                                                                                                                                                                                                                                                                                              |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>oErrorInfo.Feature</b>             | An object whose properties provide information about the feature that was being transferred when the error occurred. If the error is not associated with a particular feature, or the feature cannot be identified, this property is not set; test for this case by checking the value of IsObject (oErrorInfo.Feature). |
| <b>oErrorInfo.Feature.DisplayName</b> | The display name of the feature that was being transferred when the error occurred. If you did not specify a display name for this feature, this string is null ("").                                                                                                                                                    |
| <b>oErrorInfo.Feature.Name</b>        | The name of the feature that was being transferred when the error occurred.                                                                                                                                                                                                                                              |
| <b>oErrorInfo.Feature.Description</b> | A string describing the file transfer error. This string may be null ("").                                                                                                                                                                                                                                               |
| <b>oErrorInfo.LastError</b>           | The numeric code for the file transfer error.                                                                                                                                                                                                                                                                            |

            SprintfBox (SEVERE, "", szErrMsg, nResult);
            return nResult;
    endswitch;

end;

```

## FeatureFileEnum

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureFileEnum** function builds a list of the files in a component associated with the specified feature or a list of the components associated with a particular feature.

**Note** ▪ This function cannot be used with script-created feature sets.

### Syntax

```
FeatureFileEnum ( szFeatureSource, szFeature, szQuery, listFilesorComponents, nOption );
```

## Parameters

**Table 49** ▪ FeatureFileEnum Parameters

| Parameter                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>szFeatureSource</b>       | Pass MEDIA in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>szFeature</b>             | Specifies the name of the feature to be enumerated. Do not pass a null string ("") in this parameter. <b>FeatureFileEnum</b> requires a specific feature name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>szQuery</b>               | <p>To query the components in a particular feature, specify a component specification (same format as a file specification). Delimit the component specification with double backslashes and enclose the expression in double quotation marks.</p> <p>The component specification can include wild-card characters: an asterisk (*) as a substitute for zero or more characters, or a question mark (?) as a substitute for a single character. The following example specifies all of the components in the feature specified in szFeature:</p> <pre>"*.*"</pre> <p>To query the files in a particular component, specify a component name and a file specification. Delimit the component name and the file specification with double backslashes and enclose the expression in double quotation marks. You can also specify only a file specification. The file name part of the file specification may include wild-card characters. The following example specifies all of the files in the component Graphic_Examples:</p> <pre>"Graphic_Examples\\*.*"</pre>  <p><b>Note</b> ▪ There are limitations when using this functionality in InstallScript MSI installations (both when querying components and files), because complex wild-card expressions are not supported.</p> <p>When querying files, you must specify one of the following as szQuery:</p> <ul style="list-style-type: none"> <li>• &lt;Component Name&gt;\\*.*</li> <li>• &lt;Component Name&gt;\\&lt;Complete File Name&gt;</li> <li>• &lt;Component Name&gt;\\*.&lt;Extension&gt;</li> <li>• &lt;Component Name&gt;\\&lt;File Name&gt;.*</li> </ul> <p>When querying components, you must specify one of the following as szQuery:</p> <ul style="list-style-type: none"> <li>• *.*</li> <li>• &lt;Complete Component&gt;</li> </ul> |
| <b>listFilesOrComponents</b> | When querying components, returns a list of the components that match szQuery. When querying files, returns a list of the names of all files that match szQuery. The string list identified by listFilesOrComponents must already have been initialized by a call to <a href="#">ListCreate</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 49** ▪ FeatureFileEnum Parameters (cont.)

| Parameter      | Description                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------|
| <b>nOption</b> | Pass NO_SUBDIR in this parameter. Note that nOptions is ignored when querying the list of components. |

## Return Values

**Table 50** ▪ FeatureFileEnum Return Values

| Return Value | Description                     |
|--------------|---------------------------------|
| <b>0</b>     | FeatureFileEnum was successful. |
| <b>&lt;0</b> | FeatureFileEnum failed.         |

## FeatureFileEnum Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureFileEnum function.
 *
 * Notes: To run this example script, create a project with the
 *        following features (f), subfeatures (sf), and
 *        components (c):
 *
 *        (f) Program_Files
 *            (c) Program_DLLS
 *            (c) Program_EXEs
 *        (f) Example_Files
 *            (sf) Graphics
 *                (c) Graphic_Examples
 *
 *        Be sure to assign files to the components so there
 *        is something to enumerate.
 *

## FeatureFileInfo

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

*Note that this function does not work with files in InstallScript Object projects.*

The **FeatureFileInfo** retrieves information on a file in the file media that is referenced by szFeatureSource (MEDIA).

**Note** ▪ This function cannot be used with script-created features.

### Syntax

```
FeatureFileInfo ( szFeatureSource, szFeature, szFile, nInfo, nvResult, svResult );
```

## Parameters

**Table 51** ▪ FeatureFileInfo Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Pass MEDIA in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>szFeature</b>       | Specifies the feature containing the component in which the file is found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szFile</b>          | <p>Specifies the component and the file name, with or without a path. Delimit tokens in the szFile expression with double backslashes and enclose the expression in double quotation marks.</p> <ul style="list-style-type: none"> <li>● If there are two tokens in szFile, the first is the component name and the second is the file name:<br/> "component\\file name"</li> <li>● If there are more than two tokens in szFile, the first is the component name, the last is the file name, and the middle tokens form the path:<br/> "component\\path\\file name"</li> </ul> <p>For example:</p> <ul style="list-style-type: none"> <li>● "Shared_Files\\Is5.dll"—Shared_Files is a component and Is5.dll is a file name.</li> <li>● "Shared_Files\\dev\\myapp\\dlls\\Is5.dll"—Shared_Files is a component, \\dev\\myapp\\dlls is a path, and Is5.dll is a file name.</li> </ul>  <p><b>Note</b> ▪ InstallShield lets you add entire file and folder structures to your components by dragging and dropping them in the Files view.</p> |

**Table 51** • FeatureFileInfo Parameters (cont.)

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nInfo</b> | <p>Specifies the type of information to be retrieved. Pass a constant in this parameter. The available constants apply to either a specified component, or a specified file in a component.</p> <p>The available file-specific constants are:</p> <ul style="list-style-type: none"> <li>● <b>FEATURE_INFO_ATTRIBUTE</b>—Attribute values for the specified file. For more information about the File table attributes that are returned, see the <a href="#">Windows Installer Help</a>. Only InstallScript MSI projects support this constant; InstallScript projects do not support it.</li> <li>● <b>FEATURE_INFO_DATE</b>—Date value for the specified file in the format mm-dd-yy. Only InstallScript projects support this constant; InstallScript MSI projects do not support it. If this constant is used with <b>FeatureFileInfo</b> in an InstallScript MSI installation, the function returns failure.</li> <li>● <b>FEATURE_INFO_DATE_EX</b>—Date value for the specified file in the 2000-compliant format mm-dd-yyyy. Only InstallScript projects support this constant; InstallScript MSI projects do not support it. If this constant is used with <b>FeatureFileInfo</b> in an InstallScript MSI installation, the function returns failure.</li> <li>● <b>FEATURE_INFO_TIME</b>—Time value for the specified file in the format hh:mm, using 24-hour time. Only InstallScript projects support this constant; InstallScript MSI projects do not support it. If this constant is used with <b>FeatureFileInfo</b> in an InstallScript MSI installation, the function returns failure.</li> <li>● <b>FEATURE_INFO_VERSIONLS</b>—The minor version number or numbers in string form.</li> <li>● <b>FEATURE_INFO_VERSIONMS</b>—The major version number or numbers in string form.</li> <li>● <b>FEATURE_INFO_VERSIONSTR</b>—The entire version number in string form.</li> <li>● <b>FEATURE_INFO_MD5_SIGNATURE</b>—Returns the MD5 signature of the file specified by szFile. Note that this information is generated during the media build, so calling this function with this parameter does not cause the MD5 signature to be generated.</li> </ul> |

**Note** • Raw MD5 signature data for a particular file consists of 16 generated numeric values of 16 bit each (between 0x00 and 0xFF). These values are usually stored in a string of unsigned characters. However, the InstallScript language does not support unsigned characters, so instead of returning the raw MD5 file data, each of the 16 numeric values are converted to their string equivalent and placed in the resulting string. This results in a string of 32 characters, where each set of two characters represent a single numeric value. This is sometimes referred to as a MD5 hex string.

**Table 51** ▪ FeatureFileInfo Parameters (cont.)

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nInfo (cont.)</b> | <ul style="list-style-type: none"> <li>● <b>FEATURE_INFO_ORIGSIZE_HIGH</b>—Returns the upper 31 bits of size of the original file. If the original size of the file is more than 2 GB, the size of the file is equal to the value returned for FEATURE_INFO_ORIGSIZE_HIGH multiplied by 2 GB added to the value returned for FEATURE_INFO_ORIGSIZE_LOW. Only InstallScript installations support this constant.</li> <li>● <b>FEATURE_INFO_ORIGSIZE_LOW</b>—Returns the lower 31 bits of size of the original file. If the original size of the file is more than 2 GB, the size of the file is equal to the value returned for FEATURE_INFO_ORIGSIZE_HIGH multiplied by 2 GB added to the value returned for FEATURE_INFO_ORIGSIZE_LOW.</li> <li>● <b>FEATURE_INFO_COMPsize_LOW</b>—Returns the lower 31 bits of size of the compressed file. If the compressed size of the file is more than 2 GB, the size of the file is equal to the value returned for FEATURE_INFO_COMPsize_HIGH multiplied by 2 GB added to the value returned for FEATURE_INFO_COMPsize_LOW.</li> <li>● <b>FEATURE_INFO_COMPsize_HIGH</b>—Returns the upper 31 bits of size of the compressed file. If the original size of the file is more than 2 GB, the size of the file is equal to the value returned for FEATURE_INFO_ORIGSIZE_HIGH multiplied by 2 GB added to the value returned for FEATURE_INFO_ORIGSIZE_LOW. Only InstallScript installations support this constant.</li> </ul> |

**Note** ▪ You can use the **ConvertSizeToUnits** function to convert these values into a single value of KBYTES, MBYTES, GBYTES, or TBYTES.

**Table 51** • FeatureFileInfo Parameters (cont.)

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nInfo (cont.)</b> | <p>The available component-specific constants are:</p> <ul style="list-style-type: none"> <li>● <b>FEATURE_INFO_COMPONENT_FLAGS</b>—General flags that are set for the specified component. Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> <li>● <b>FEATURE_INFO_DESTINATION</b>—Destination setting for the component. Note that any text substitutions that are included in the destination are not resolved in the returned string. To determine the component's destination with any text substitutions resolved, call <b>TextSubSubstitute</b> on the returned string.</li> <li>● <b>FEATURE_INFO_DOTNET</b>—.NET flags that are selected for the specified component. Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> <li>● <b>FEATURE_INFO_FTPLOCATION</b>—FTP Location setting for the specified component. Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> <li>● <b>FEATURE_INFO_HTTPLOCATION</b>—HTTP Location setting for the specified component. Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> <li>● <b>FEATURE_INFO_LANGUAGE</b>—Languages setting for the specified component. Because this applies only to a component, szFile must be a single token expression identifying a component.</li> <li>● <b>FEATURE_INFO_MISC</b>—Miscellaneous setting for the specified component. Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> <li>● <b>FEATURE_INFO_OS</b>—Operating System setting for the specified component. Because this applies only to a component, szFile must be a single token expression that identifies a component. Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> <li>● <b>FEATURE_INFO_OVERWRITE</b>—Overwrite flags that are set for the specified component. Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> <li>● <b>FEATURE_INFO_PLATFORM_SUITE</b>—Platform Suites setting for the specified component. Because this applies only to a component, szFile must be a single token expression that identifies a component. Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> </ul> |

**Table 51** • FeatureFileInfo Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvResult</b> | <p>Specifies information that is dependent on the constant that is passed in nInfo.</p> <p>When nInfo is FEATURE_INFO_ORIGSIZE_HIGH, FEATURE_INFO_ORIGSIZE_LOW, or FEATURE_INFO_ATTRIBUTE, nvResult returns a number value.</p> <p>When nInfo is FEATURE_INFO_ATTRIBUTE, nvResult returns a numeric value that represents the file attributes from the Windows Installer File table. To determine the file attribute settings, use file attribute constants in bitwise OR operations with nvResult. For an example of how to test nvResult, see <a href="#">FeatureFileInfo Example</a>. For more information about the File table attributes, see the <a href="#">Windows Installer Help</a>.</p> <p>When nInfo is FEATURE_INFO_LANGUAGE or FEATURE_INFO_OS, the parameter position occupied by nvResult must specify a LIST variable to store the language or operating system IDs. You must call <a href="#">ListCreate</a> with the constant NUMBERLIST to create the list before you call <b>FeatureFileInfo</b> to determine which languages or operating systems are specified by the component:</p> <pre>listID = ListCreate(NUMBERLIST);</pre> <pre>FeatureFileInfo(szFeatureSource, szFeature, szFile,<br/>FEATURE_INFO_LANGUAGE, listID, svResult);</pre> <p>When nInfo is FEATURE_INFO_LANGUAGE, <b>FeatureFileInfo</b> adds language IDs to the list; when nInfo is FEATURE_INFO_OS, <b>FeatureFileInfo</b> adds operating system IDs to the list.</p> <p>When nInfo is FEATURE_INFO_COMPONENT_FLAGS, nvResult returns one or more of the following values:</p> <ul style="list-style-type: none"> <li>● FEATURE_INFO_COMPONENT_FLAG_COMPRESSED—The component's Compressed setting is Yes.</li> <li>● FEATURE_INFO_COMPONENT_FLAG_DATAASFILES—The component's files are placed in a particular folder for a CD-ROM type of release. (This is determined by the CD-ROM Folder setting for the feature that contains the component.) Only InstallScript projects support this constant; InstallScript MSI projects do not support it.</li> <li>● FEATURE_INFO_COMPONENT_FLAG_DONTUNINSTALL—The component's Uninstall setting is No.</li> <li>● FEATURE_INFO_COMPONENT_FLAG_ENCRYPTED—The component is encrypted. (This is determined by whether the feature that includes the component has Yes selected for its Encryption setting.)</li> <li>● FEATURE_INFO_COMPONENT_FLAG_POTENTIALLYLOCKED—The component's Potentially Locked setting is Yes.</li> <li>● FEATURE_INFO_COMPONENT_FLAG_SELFREGISTERING—The component's Self-Register setting is Yes.</li> <li>● FEATURE_INFO_COMPONENT_FLAG_SHARED—The component's Shared setting is Yes.</li> </ul> |

**Table 51** ▪ FeatureFileInfo Parameters (cont.)

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvResult (cont.)</b> | <p>When ninfo is FEATURE_INFO_OVERWRITE, nvResult returns one or more of the following values:</p> <ul style="list-style-type: none"> <li>● FEATURE_VALUE_ALWAYS—The component's Overwrite setting is Always.</li> <li>● FEATURE_VALUE_DATE_NEWER—The component's Overwrite setting is Newer Date.</li> <li>● FEATURE_VALUE_DATE_OLDER—The component's Overwrite setting is Older Date.</li> <li>● FEATURE_VALUE_DATE_SAME—The component's Overwrite setting is Same or Newer Date.</li> <li>● FEATURE_VALUE_NEVER—The component's Overwrite setting is Never.</li> <li>● FEATURE_VALUE_VERSION_NEWER—The component's Overwrite setting is Newer Version.</li> <li>● FEATURE_VALUE_VERSION_OLDER—The component's Overwrite setting is Older Version.</li> <li>● FEATURE_VALUE_VERSION_SAME—The component's Overwrite setting is Same or Newer Version.</li> </ul> <p>Note that nvResult could contain both date and version values.</p> <p>When ninfo is FEATURE_INFO_DOTNET, nvResult may return the following value:</p> <p>FEATURE_VALUE_LOCAL_ASSEMBLY—The component is marked as a local assembly.</p> |
| <b>svResult</b>         | Returns the date, time, or version when nInfo specifies a corresponding information type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Return Values

**Table 52** ▪ FeatureFileInfo Return Values

| Return Value | Description                     |
|--------------|---------------------------------|
| <b>0</b>     | FeatureFileInfo was successful. |
| <b>&lt;0</b> | FeatureFileInfo failed.         |

## FeatureFileInfo Example

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* Demonstrates the FeatureFileInfo function.
*
* This script calls FeatureFileInfo repeatedly to retrieve
* information about the file media. The information is stored
* in a list and then displayed.
*
* Note: To run this example script, create a project with the
*       following features (f), subfeatures (sf), and
*       components (c):
*
*       (f) Example_Files
*           (sf) Graphics
*               (c) Graphic_Examples
*
*       Be sure to assign at least one file to the Graphic_Examples
* component so there is something to enumerate.
*       Also, remember to specify the file name in the #define
*       FILE line.
*
\*-----*/

#define FEAT          "Example Files"

```

# FeatureFilterLanguage

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureFilterLanguage** function filters (excludes) files from file transfer based on language. By default, all languages included in the media build are unfiltered (included). You must call **FeatureFilterLanguage** for each language you wish to filter or unfilter.

**Note** ▪ This function cannot be used with script-created feature sets.

## Filtering Language-Specific Components

### Task

**To filter language-specific components during the installation:**

1. Filter (exclude) all languages by calling **FeatureFilterLanguage** with `ISLANG_ALL` in the parameter `nLangID` and `bFiltered` set to `TRUE`.
2. For each language that you want to install, call **FeatureFilterLanguage** with the appropriate language constant in `nLangID` and with the parameter `bFiltered` parameter set to `FALSE`. Each call unfilters (includes) components for the language specified in `nLangID`.

**Note** ▪ You cannot specify multiple language constants in the `nLangID` parameter by using the OR operator ( `|` ). Specifying multiple language constants causes the function to perform incorrectly.

## Supporting Different Languages

InstallShield allows you to designate components for any language or language subgroup that is supported by Windows. However, in order for the Release Wizard to build a language-specific component, you must have support for the language of that component. Your setup must also support the language of the component.

If your setup includes language-specific components that are designated as specific to a language not supported by InstallShield or by your setup, the components are filtered (not included) by the Release Wizard.

## Using FeatureFilterLanguage With GetSystemInfo

When using **FeatureFilterLanguage** in conjunction with the **GetSystemInfo** function, you must consider the following: The language constants that can be used to designate language-specific components are a small subset of the language constants that can be returned by **GetSystemInfo**.

If your setup includes language filtering based on these return values, you must use a switch statement to convert constants returned by this function into one of the constants supported for language filtering.

## Syntax

```
FeatureFilterLanguage ( szFeatureSource, nLangID, bFiltered );
```

## Parameters

**Table 53** • FeatureFilterLanguage Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media.                                                                                                                                                                                                                                                                                                                                                                                |
| <b>nLangID</b>         | Specifies the ID of the language to filter or unfilter. Only <i>one</i> language constant can be specified for each function call. To filter all languages, pass ISLANG_ALL in this parameter. See <a href="#">Language IDs</a> to learn more.                                                                                                                                                                             |
| <b>bFiltered</b>       | Indicates whether to filter (exclude) or unfilter (include) the language specified in nLangID. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Filter the language specified in nLangID—do not include it in the file transfer.</li> <li>• <b>FALSE</b>—Do not filter the language specified in nLangID—include it in the file transfer.</li> </ul> |

## Return Values

**Table 54** • FeatureFilterLanguage Return Values

| Return Value  | Description                           |
|---------------|---------------------------------------|
| <b>0</b>      | FeatureFilterLanguage was successful. |
| <b>&lt; 0</b> | FeatureFilterLanguage failed.         |

## FeatureFilterLanguage Example

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FeatureFilterLanguage function.
*
* First, FeatureFilterLanguage is called to exclude all
* languages. Next, GetSystemInfo is called to determine the
* target computer's default language/locale.
*
* Then, FeatureFilterLanguage is called again to include the
* language appropriate for the target computer. If language
* support is not provided for the target computer, English is
* used. Finally, the FeatureMoveData is called to create the
* installation.
```

```

*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FeatureFilterLanguage(HWND);

function ExFn_FeatureFilterLanguage(hMSI)
    STRING  szResult;
    NUMBER  nResult, nDisk;
begin

    // Filter out all language-specific file groups.
    FeatureFilterLanguage (MEDIA, ISLANG_ALL, TRUE);

    // Retrieve the target machine's default language/locale setting.
    GetSystemInfo (LANGUAGE, nResult, szResult);

    // Turn off filtering for file groups specific to the target
    // machine's default language/locale setting.

    switch (nResult)
        case ISLANG_FRENCH_CANADIAN:
            FeatureFilterLanguage (MEDIA, ISLANG_FRENCH_CANADIAN, FALSE);
        case ISLANG_FRENCH_STANDARD, ISLANG_FRENCH_BELGIAN, ISLANG_FRENCH_SWISS,
ISLANG_FRENCH_LUXEMBOURG:
            FeatureFilterLanguage (MEDIA, ISLANG_FRENCH_STANDARD, FALSE );
        case ISLANG_GERMAN_STANDARD, ISLANG_GERMAN_SWISS, ISLANG_GERMAN_AUSTRIAN,
ISLANG_GERMAN_LUXEMBOURG, ISLANG_GERMAN_LIECHTENSTEIN:
            FeatureFilterLanguage (MEDIA, ISLANG_GERMAN, FALSE);
        // Use English as a default.
        default:
            FeatureFilterLanguage (MEDIA, ISLANG_ENGLISH_UNITEDSTATES, FALSE);
    endswitch;

    // Transfer files for selected language.
    FeatureMoveData (MEDIA, nDisk, 0);

end;

```

## FeatureFilterOS

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **FeatureFilterOS** function filters components that are flagged for specified operating systems and suites.

**Note** ▪ This function cannot be used with script-created feature sets.

Any filtering that is done when the installation is first run must also be done during maintenance mode. Be sure to call this function in code that is executed during both initial and maintenance installations. Do not call this function from the following event handlers: OnAppSearch, OnCCPSearch, OnFirstUIBefore, OnFirstUIAfter, OnMaintUIBefore, or OnMaintUIAfter.

---

**Project** • Components are not filtered by default in an InstallScript MSI installation.

In an InstallScript installation, **FeatureFilterOS** is called by the default *OnFilterComponents* event handler during both initial and maintenance installations. This event handler filters components by default that are specific to operating systems and suites other than those on the target system. An installation that is run in maintenance mode has no information about the filtering that was done during the initial installation.

## Syntax

```
FeatureFilterOS ( szMediaLibrary, nSuites, nOS, bFiltered );
```

## Parameters

**Table 55** ▪ FeatureFilterOS Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMediaLibrary</b> | Specifies the media name of the file media library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>nSuites</b>        | <p>Specifies the operating system suite or suites that you want to filter. Choose from the following values. You can combine values using the bitwise OR operator (   ).</p>  <p><b>Note</b> ▪ The suites listed here are those that can be specified in the Windows API's OSVERSIONINFOEX data structure.</p> <ul style="list-style-type: none"> <li>• <b>ISOS_ST_ALL</b>—All Windows suites</li> <li>• <b>ISOS_ST_XP_PRO</b>—Windows XP Professional</li> <li>• <b>ISOS_ST_XP_HOME</b>—Windows XP Home Edition</li> <li>• <b>ISOS_ST_SERVER</b>—Windows Server</li> <li>• <b>ISOS_ST_WORKSTATION</b>—Windows Workstation</li> <li>• <b>ISOS_ST_BACKOFFICE</b>—Microsoft BackOffice</li> <li>• <b>ISOS_ST_DATACENTER</b>—Windows Server Datacenter</li> <li>• <b>ISOS_ST_ENTERPRISE</b>—Windows Server Enterprise</li> <li>• <b>ISOS_ST_SERVER2003_R2</b>—Microsoft Windows Server 2003 R2</li> <li>• <b>ISOS_ST_SMALLBUSINESS</b>—Microsoft Small Business Server</li> <li>• <b>ISOS_ST_SMALLBUSINESS_RESTRICTED</b>—Microsoft Small Business Server with the restrictive client license</li> <li>• <b>ISOS_ST_TERMINAL</b>—Microsoft Terminal Services</li> <li>• <b>ISOS_ST_PROC_ARCH_32</b>—32-bit Processors</li> <li>• <b>ISOS_ST_PROC_ARCH_IA64</b>—Intel Itanium 64-bit Processor</li> <li>• <b>ISOS_ST_PROC_ARCH_AMD64</b>—AMD Athalon 64-bit Processor</li> <li>• <b>0 (zero)</b>—Specifies that FeatureFilterOS ignores components' Platform Suite properties</li> </ul>  <p><b>Project</b> ▪ InstallScript MSI projects do not have support for platform suites. Therefore, in an InstallScript MSI project, you must specify the number 0 for nSuites. Otherwise, the function fails and the information that is specified in nOS is ignored.</p> |

**Table 55** ▪ FeatureFilterOS Parameters (cont.)

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nOS       | <p>Specifies the operating system or operating systems that you wish to filter. Choose from the following values. You can combine values using the bitwise OR operator ( ).</p> <ul style="list-style-type: none"> <li>• <b>ISOSL_ALL</b>—All Windows systems</li> <li>• <b>ISOSL_WINXP</b>—Windows XP Edition</li> <li>• <b>ISOSL_WINSERVER2003</b>—Windows Server 2003</li> <li>• <b>ISOSL_WINVISTA_SERVER2008 (or ISOSL_WINVISTA)</b>—Windows Vista or Windows Server 2008</li> <li>• <b>ISOSL_WIN7_SERVER2008R2</b>—Windows 7 or Windows Server 2008 R2</li> <li>• <b>ISOSL_WIN8</b>—Windows 8 or Windows Server 2012</li> <li>• <b>ISOSL_WIN81</b>—Windows 8.1 or Windows Server 2012 R2</li> <li>• <b>ISOSL_WIN10</b>—Windows 10</li> <li>• <b>ISOSL_WIN10_SERVER2019</b>—Windows Server 2019</li> <li>• <b>ISOSL_WIN11</b>—Windows 11</li> <li>• <b>ISOSL_WIN10_SERVER2022</b>—Windows Server 2022</li> </ul> <p></p> <p><b>Note</b> ▪ Several client and server versions of Windows use the same major and minor version numbers:</p> <ul style="list-style-type: none"> <li>• Windows 8.1 and Windows Server 2012 R2 use the same major and minor version numbers.</li> <li>• Windows 8 and Windows Server 2012 use the same major and minor version numbers.</li> <li>• Windows 7 and Windows Server 2008 R2 use the same major and minor version numbers.</li> <li>• Windows Vista and Windows Server 2008 have the same major and minor version numbers.</li> </ul> <p>Therefore, for these operating system versions, the installation considers the client versions to be the same as the equivalent server versions; thus, components that are marked for the client version are also installed on the server version. To distinguish between the client and server versions, you can check whether <code>SYSINFO.nOSProductType</code> is equal to <code>VER_NT_WORKSTATION</code>; on client versions, this is true. On server versions, this is false.</p> |

**Table 55** • FeatureFilterOS Parameters (cont.)

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bFiltered</b> | <p>Specifies whether to filter (exclude) or unfilter (include) the operating systems specified in nOS. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Filter the specified operating system—do not include them in the file transfer.</li> <li>• <b>FALSE</b>—Do not filter the specified operating system—include them in the file transfer.</li> </ul> |

## Return Values

**Table 56** • FeatureFilterOS Return Values

| Return Value  | Description                                                                         |
|---------------|-------------------------------------------------------------------------------------|
| <b>0</b>      | <b>FeatureFilterOS</b> was successful.                                              |
| <b>&lt; 0</b> | <b>FeatureFilterOS</b> failed. Call <b>FeatureError</b> for additional information. |

## Additional Information

While both **ISOSL\_ALL** and **ISOSL\_SUPPORTED** specify all Windows systems when passed as the third argument to **FeatureFilterOS**, they have different numeric values. **ISOSL\_ALL** is zero (0) and **ISOSL\_SUPPORTED** is the value obtained by combining every operating system constant using the bitwise OR operator, that is, **ISOSL\_WIN7\_SERVER2008R2 | ISOSL\_WINVISTA\_SERVER2008 | ...**. In some cases, you may find it useful to perform bitwise operations on **ISOSL\_SUPPORTED** and other operating system constants.

## FeatureFilterOS Example

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FeatureFilterOS function.
*
* To run this script, create a blank setup project.
* Specify Windows 95, Windows 98, and Windows NT 4.0
* (Intel) for operating systems in the Components view.
* Use release flags to specify which platforms to include
* in the build. Specify Windows 95, Windows 98, and Windows
* NT 4.0 (Intel). When you run the Release Wizard, enter the
* release flags in the Filtering Settings panel.

# FeatureGetCost

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureGetCost** function is obsolete. Use the **FeatureGetCostEx** function instead.

The **FeatureGetCost** function determines the total space, in kilobytes (KB), required on the target drive for the feature that is specified by `szFeature`. When determining required drive space, this function takes into account whether the feature is currently selected, whether any components associated with the feature are currently filtered by operating system or language, and the cluster size on the target drive.

## Syntax

```
FeatureGetCost ( szFeatureSource, szFeature, szTargetDir, nvRequiredSpace );
```

## Parameters

**Table 57** ▪ FeatureGetCost Parameters

| Parameter              | Description                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media whose features have been specified for installation and uninstallation. Typically, you would pass the system variable <b>MEDIA</b> in this parameter. |
| <b>szFeature</b>       | Specifies the feature for which you want to determine the total space that is required on the target drive.                                                                                      |
| <b>szTargetDir</b>     | Specifies the drive that is used, or the path whose drive is used, in determining required drive space. Typically, you would pass the system variable <b>TARGETDIR</b> in this parameter.        |
| <b>nvRequiredSpace</b> | Returns the required drive space, in KB.                                                                                                                                                         |

## Return Values

**Table 58** ▪ FeatureGetCost Return Values

| Return Value  | Description                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully determined the required drive space.                                                                                                                                                                |
| <b>&lt; 0</b> | Indicates that the function could not determine the required drive space.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <b>FormatMessage</b> . |

## FeatureGetCost Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureGetCost function.
 *
 * This example script displays a dialog that shows the user
 * the size of each top-level feature that they selected.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features
 *           and/or subfeatures with components containing
 *           files.
 *
 \*-----*/

#include "Ifx.h"

```

```

function OnBegin()
    string svDir, svFeature, svFeatureInfo;
    LIST listFeatures, listFeatureInfo;
    number nListGetString, nvRequiredSpace;
begin
    svDir = TARGETDIR;
    SdFeatureTree ("", "", svDir, "", 1);

    listFeatures = ListCreate ( STRINGLIST );
    FeatureListItems ( MEDIA, "", listFeatures );
    nListGetString = ListGetFirstString ( listFeatures, svFeature );
    listFeatureInfo = ListCreate ( STRINGLIST );
    while nListGetString=0
        FeatureGetCost ( MEDIA, svFeature, svDir, nvRequiredSpace );
        Sprintf ( svFeatureInfo, "Selected feature %s has a size of %ld KB.\n",
            svFeature, nvRequiredSpace );
        ListAddString ( listFeatureInfo, svFeatureInfo, AFTER );
        nListGetString = ListGetNextString ( listFeatures, svFeature );
    endwhile;
    ListDestroy ( listFeatures );

    SdShowInfoList ( "", "", listFeatureInfo );
    ListDestroy ( listFeatureInfo );
end;

```

## FeatureGetCostEx

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureGetCostEx** function returns the cost of the specified feature (in bytes) using the **nvCostHigh** and **nvCostLow** parameters. If **szFeature** is "", the cost of the entire media is returned. This function replaces the **FeatureGetCost** and **FeatureGetTotalCost** functions.

### Syntax

```
FeatureGetCostEx ( szMediaSource, szFeature, szTarget, nvCostHigh, nvCostLow );
```

## Parameters

**Table 59** ▪ FeatureGetCostEx Parameters

| Parameter            | Description                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMediaSource</b> | The media source, typically MEDIA.                                                                                                                                                |
| <b>szFeature</b>     | Specifies the feature to get the cost of. If this value is "", the function returns the cost of the entire media.                                                                 |
| <b>szTarget</b>      | Specifies the target directory for the feature specified by szFeature.                                                                                                            |
| <b>nvCostHigh</b>    | Returns the upper 31 bits of the cost of the feature. Each cost unit returned represents 2GB of cost. For example, a value of 4 for this variable represents a cost of 8GB.       |
| <b>nvCostLow</b>     | Returns the lower 31 bits of the cost of the feature. The maximum value for this variable is 1 or 2GB of cost. Any cost greater than this is returned in the nvCostHigh variable. |

## Return Values

**Table 60** ▪ FeatureGetCostEx Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# FeatureGetData

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureGetData** function retrieves information about a feature.

## Syntax

```
FeatureGetData ( szFeatureSource, szFeature, nInfo, nvResult, svResult );
```

## Parameters

**Table 61** • FeatureGetData Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>szFeatureSource</b> | Specifies the media name of the script-created feature set or (in InstallScript projects) file media library that contains the feature for which information is retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>szFeature</b>       | Specifies the name of the feature from which information is retrieved. To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>nInfo</b>           | <p>Specifies the type of information to retrieve. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FEATURE_FIELD_CDROM_FOLDER</b>—For a CD-ROM media type, the location of the feature's data on the CD-ROM. Only InstallScript projects support this constant; InstallScript MSI projects do not. This constant is available for file media libraries, not for script-created feature sets.</li> <li>● <b>FEATURE_FIELD_DESCRIPTION</b>—The description displayed when the feature is selected in a feature selection dialog. This is the text from the feature's Description property.</li> <li>● <b>FEATURE_FIELD_DISPLAYNAME</b>—The feature name displayed in the selection dialogs. This is the value in the feature's Display Name setting.</li> <li>● <b>FEATURE_FIELD_ENCRYPT</b>—Specifies whether the feature is encrypted. Only InstallScript projects support this constant; InstallScript MSI projects do not. This constant is available for file media libraries, not for script-created feature sets.</li> <li>● <b>FEATURE_FIELD_FILENEED</b>—Defines how critical the feature files are for the installation. Only InstallScript projects support this constant; InstallScript MSI projects do not.</li> <li>● <b>FEATURE_FIELD_FLAGS</b>—Indicates the flags that are set for the feature. Only InstallScript projects support this constant; InstallScript MSI projects do not. This constant is available for file media libraries, not for script-created feature sets.</li> <li>● <b>FEATURE_FIELD_FTPLOCATION</b>—Specifies an FTP location. This value is stored in the feature's FTP Location setting.</li> <li>● <b>FEATURE_FIELD_GUID</b>—The GUID that is associated with the feature. Only InstallScript projects support this constant; InstallScript MSI projects do not. This constant is available for file media libraries, not for script-created feature sets.</li> </ul> |

**Table 61** • FeatureGetData Parameters (cont.)

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nInfo (cont.)</b> | <ul style="list-style-type: none"> <li>● <b>FEATURE_FIELD_HANDLER_ONINSTALLED</b>—The name of the OnInstalled event for the feature. This constant is available for file media libraries, not for script-created feature sets.</li> <li>● <b>FEATURE_FIELD_HANDLER_ONINSTALLING</b>—The name of the OnInstalling event for the feature. This constant is available for file media libraries, not for script-created feature sets.</li> <li>● <b>FEATURE_FIELD_HANDLER_ONUNINSTALLED</b>—The name of the OnUninstalled event for the feature. This constant is available for file media libraries, not for script-created feature sets.</li> <li>● <b>FEATURE_FIELD_HANDLER_ONUNINSTALLING</b>—The name of the OnUninstalling event for the feature. This constant is available for file media libraries, not for script-created feature sets.</li> <li>● <b>FEATURE_FIELD_HTTPLOCATION</b>—Specifies an HTTP location. This value is stored in the feature's HTTP Location setting.</li> <li>● <b>FEATURE_FIELD_IMAGE</b>—Specifies the index of the icon to be displayed in nvResult. If no icon should be displayed for the feature, nvResult returns -1.</li> <li>● <b>FEATURE_FIELD_MISC</b>—Miscellaneous text. This field can be useful at run time because you can use it to flag or identify features using any information you want.</li> <li>● <b>FEATURE_FIELD_PASSWORD</b>—Specifies whether a password is associated with the feature. This constant is available for file media libraries, not for script-created feature sets. Only InstallScript projects support this constant; InstallScript MSI projects do not.</li> <li>● <b>FEATURE_FIELD_SELECTED</b>—Indicates whether the feature specified in szFeature is selected.</li> <li>● <b>FEATURE_FIELD_SIZE</b>—Total original file size for the feature specified in szFeature. This constant is available for file media libraries, not for script-created feature sets.</li> <li>● <b>FEATURE_FIELD_STATUS</b>—In InstallScript installations, this text is displayed in the progress indicator during file transfer. This constant is available for file media libraries, not for script-created feature sets. In InstallScript MSI installations, the feature's display name is returned.</li> <li>● <b>FEATURE_FIELD_VISIBLE</b>—Determines whether the feature that is specified in szFeature is visible in the selection dialog. This value is stored in the feature's Display setting.</li> </ul> |

**Table 61** • FeatureGetData Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvResult</b> | <p>Returns a numeric value when nInfo produces a numeric result.</p> <p>When nInfo is FEATURE_FIELD_FILENEED, nvResult returns one of the following values:</p> <ul style="list-style-type: none"> <li>● <b>FEATURE_VALUE_CRITICAL</b>—This feature contains critical files.</li> <li>● <b>FEATURE_VALUE_HIGHLYRECOMMENDED</b>—This feature is highly recommended.</li> <li>● <b>FEATURE_VALUE_STANDARD</b>—This feature may or may not be included.</li> </ul> <p>When nInfo is FEATURE_FIELD_FLAGS, nvResult returns one of the following values:</p> <ul style="list-style-type: none"> <li>● <b>FEATURE_DATA_FLAG_PASSWORD</b>—The feature is password protected.</li> <li>● <b>FEATURE_DATA_FLAG_PASSWORD_VALIDATED</b>—The feature's password has been validated. (The installation is using <b>FeatureValidate</b> or the feature is not password protected.)</li> <li>● <b>FEATURE_DATA_FLAG_DATA_AS_FILES</b>—The feature's files are placed in a particular folder for a CD-ROM type of release.</li> <li>● <b>FEATURE_DATA_FLAG_SPLIT_AFTER</b>—This flag is set only for build-generated features.</li> <li>● <b>FEATURE_DATA_FLAG_SPLIT_BEFORE</b>—This flag is set only for build-generated features.</li> <li>● <b>FEATURE_DATA_FLAG_SPLIT_BEFORE_NOT_ALLOWED</b>—This flag is set only for build-generated features.</li> <li>● <b>FEATURE_DATA_FLAG_SPLIT_NOT_ALLOWED</b>—This flag is set only for build-generated features.</li> <li>● <b>FEATURE_DATA_FLAG_VISIBLE</b>—The feature is visible.</li> <li>● <b>FEATURE_DATA_FLAG_VOLATILE</b>—The feature is volatile.</li> <li>● <b>FEATURE_DATA_FLAG_ENCRYPTED</b>—The feature is encrypted.</li> </ul> |

**Table 61** • FeatureGetData Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <p>When <code>nInfo</code> is <code>FEATURE_FIELD_PASSWORD</code>, <code>nvResult</code> returns one of the following values:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—The feature is password protected. If the feature is password protected, you must get the correct password from the end user and validate it with <b>FeatureValidate</b> before calling <b>FeatureTransferData</b> to transfer the files in the file media library.</li> <li>● <b>FALSE</b>—The feature is not password protected.</li> </ul> <p>When <code>nInfo</code> is <code>FEATURE_FIELD_SELECTED</code>, <code>nvResult</code> returns one of the following values:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—This feature is selected.</li> <li>● <b>FALSE</b>—This feature is not selected.</li> </ul> <p>When <code>nInfo</code> is <code>FEATURE_FIELD_VISIBLE</code>, <code>nvResult</code> returns one of the following values:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—This feature is visible.</li> <li>● <b>FALSE</b>—This feature is not visible.</li> </ul> |
| <b>svResult</b> | Returns a string value when <code>nInfo</code> produces a string result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Return Values

| Return Value  | Description                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | FeatureGetData was successful.                                                                                                                                                                                                                       |
| <b>&lt; 0</b> | <p>FeatureGetData failed. Call <b>FeatureError</b> for additional information.</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <b>FormatMessage</b>.</p> |

## FeatureGetData Example

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FeatureGetData function.
*
* This example script demonstrates a function that retrieves
* information about a specified feature.
*
* Comments: To run this example script, create a project (or

```

```

*           insert into a project) with features and/or
*           subfeatures with components containing files.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

// Include iswi.h for Windows Installer API function prototypes and constants,
// and to declare code for the OnBegin and OnEnd events.
#include "iswi.h"

    // The keyword export identifies MyFunction() as an entry-point function.
    // The argument it accepts must be a handle to the Installer database.
    export prototype MyFunction(HWND);

    // To Do:  Declare global variables, define constants, and prototype user-
    //         defined and DLL functions here.

function MyFunction(hMSI)

    STRING  svDir, szTitle, szMsg, svResult;
    NUMBER  nvResult;

begin

    svDir   = INSTALLDIR;
    szTitle = "Select Features";
    szMsg   = "Select the features you want to install on your computer.";

    // Display available features.
    SdFeatureTree (szTitle, szMsg, svDir, "", 2);

    // Get the description property for Feature1.
    FeatureGetData (MEDIA, "Feature1", feature_FIELD_DESCRIPTION, nvResult, svResult);

    // Display the description for Feature1.
    MessageBox ("Feature1's description is: " + svResult, INFORMATION);

    // Determine whether or not Feature2 is selected.
    FeatureGetData (MEDIA, "Feature2", feature_FIELD_SELECTED, nvResult, svResult);

    // Display a message indicating whether or not Feature2 is selected.
    if nvResult=0 then
        MessageBox ("Feature2 is not selected.", INFORMATION);
    else
        MessageBox ("Feature2 is selected.", INFORMATION);
    endif;

end;

```

# FeatureGetItemSize

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **FeatureGetItemSize** function retrieves the size—in bytes—of a specified feature. The sizes of subfeatures are not included.

**Note** ▪ This function cannot be used with script-created feature sets.

## Syntax

```
FeatureGetItemSize ( szFeatureSource, szFeature, nvSize );
```

## Parameters

**Table 63** ▪ FeatureGetItemSize Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media that contains the feature whose size is to be retrieved.                                                                                                                                                                          |
| <b>szFeature</b>       | Specifies the name of the feature whose size is to be retrieved.                                                                                                                                                                                                             |
| <b>nvSize</b>          | Returns the size in bytes of the specified feature. You can also call <a href="#">FeatureGetData</a> to get the total original file size of a specified feature. Call <a href="#">FeatureTotalSize</a> to determine the total size of all selected features and subfeatures. |

## Return Values

**Table 64** ▪ FeatureGetItemSize Return Values

| Return Value  | Description                                                                              |
|---------------|------------------------------------------------------------------------------------------|
| <b>0</b>      | FeatureGetItemSize was successful.                                                       |
| <b>&lt; 0</b> | FeatureGetItemSize failed. Call <a href="#">FeatureError</a> for additional information. |

## FeatureGetItemSize Example

```
/*-----*\
 *
 * InstallShield Example Script
```

```

*
* Demonstrates the FeatureGetItemSize function.
*
* This example calls FeatureGetItemSize to get the size of
* a feature and a subfeature. The sizes are displayed
* in a dialog.
*
* Notes: To run this example script, create a project (or
*        insert into a project) with several features and/or
*        subfeatures with components containing files.
*        You must name one feature and one subfeature as
*        indicated in the #define statements in this example,
*        or change the #define statements to reference your
*        feature names.
*
\*-----*/

#define FEAT_NAME1 "Program Files"
#define FEAT_NAME2 "Example Files\\Graphics"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FeatureGetItemSize(HWND);

function ExFn_FeatureGetItemSize(hMSI)
    NUMBER nvSize;
    STRING szString;
    LIST listInfo;
begin

    // Create a string list to store feature sizes.
    listInfo = ListCreate (STRINGLIST);

    // Get the size of FEAT_NAME1.
    FeatureGetItemSize (MEDIA, FEAT_NAME1, nvSize);

    // Convert the number to a string.
    NumToStr (szString, nvSize);

    // Put the string into the list.
    ListAddString (listInfo, "The size in bytes of " + FEAT_NAME1 +
        " is: " + szString, AFTER);

    // Get the size of FEAT_NAME2.
    FeatureGetItemSize (MEDIA, FEAT_NAME2, nvSize);

    // Convert the number to a string.
    NumToStr (szString, nvSize);

    // Put the string into the list.
    ListAddString (listInfo, "The size in bytes of " + FEAT_NAME2 +
        " is: " + szString, AFTER);

    // Display the list of feature sizes.
    SdShowInfoList ("Results of Calls to FeatureGetItemSize",

```

```

        "The feature sizes are:", listInfo);

    // Release the list from memory.
    ListDestroy (listInfo);

end;
```

## FeatureGetTotalCost

---

**Note** ▪ This function is obsolete. Use the [FeatureGetCostEx](#) function instead.

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureGetTotalCost** function determines the total space, in kilobytes (KB), required on the target drive for the feature installations and uninstallations that have been specified (for example, by end user selections in feature or setup type dialogs). When determining required drive space, this function takes into account which features are currently selected, whether any components associated with the features are currently filtered by operating system or language, and the cluster size on the target drive.

### Syntax

```
FeatureGetTotalCost ( szFeatureSource, szTargetDir, nvTotalRequiredSpace );
```

## Parameters

**Table 65** • FeatureGetTotalCost Parameters

| Parameter                   | Description                                                                                                                                                                                      |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b>      | Specifies the media name of the file media whose features have been specified for installation and uninstallation. Typically, you would pass the system variable <b>MEDIA</b> in this parameter. |
| <b>szTargetDir</b>          | Specifies the drive that is used, or the path whose drive is used, in determining required drive space. Typically, you would pass the system variable <b>TARGETDIR</b> in this parameter.        |
| <b>nvTotalRequiredSpace</b> | Returns the required drive space, in KB.                                                                                                                                                         |

## Return Values

**Table 66** • FeatureGetTotalCost Return Values

| Return Value  | Description                                                                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully determined the required drive space.                                                                                                                                                                |
| <b>&lt; 0</b> | Indicates that the function could not determine the required drive space.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <b>FormatMessage</b> . |

# FeatureInitialize

**Project** • This information applies to InstallScript projects.

The **FeatureInitialize** function is supported only for compatibility with scripts created in earlier versions of InstallShield. It is recommended that you avoid using multiple file media libraries in InstallShield because they are no longer necessary and they can break your installation.

The **FeatureInitialize** function associates a media name with a file media library and prepares that media library for access.

## Syntax

```
FeatureInitialize ( szMediaLibrary, szMediaLibraryFile );
```

## Parameters

**Table 67** • FeatureInitialize Parameters

| Parameter                 | Description                                                                                                                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMediaLibrary</b>     | Specifies the media name to associate with the file media library whose files are to be transferred with <a href="#">FeatureMoveData Example</a> .<br><br>The media name Data is reserved for use with Data1.cab, the default file media library. You may not pass Data in the parameter szMediaLibrary. |
| <b>szMediaLibraryFile</b> | Specifies the file name of the file media library to be initialized. The file name must be in the format xxx1.cab; for example, second1.cab or wow1.cab. Do not specify a path; this file must reside in the installation's source folder (SRCDIR).                                                      |

## Return Values

**Table 68** • FeatureInitialize Return Values

| Return Value  | Description                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | FeatureInitialize was successful.                                                                                                                                                                     |
| <b>&lt; 0</b> | FeatureInitialize failed.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

This function cannot be used with script-created feature sets.

A file media library that is initialized with FeatureInitialize must be installed by calling **FeatureMoveData**. **FeatureTransferData** fails if called to install such a media library.

If an installation installs file media libraries that are initialized with **FeatureInitialize**, the uninstallation must be enabled by calling **DeinstallStart** rather than **MaintenanceStart**. (This is the case because files must be installed by calling **FeatureMoveData**, which does not support maintenance setups.)

The maintenance/uninstallation feature that is stored in szMediaLibraryFile is not installed by **FeatureMoveData**; only the first call to **FeatureMoveData**, before calling **FeatureInitialize**, can install a file media library's maintenance/uninstallation feature.

It is not necessary to call **FeatureInitialize** before accessing the default file media library (Data1.cab) using the default media name Data. The default media is initialized automatically during installation initialization. The file media library must reside in the installation's source folder. The name of this folder is assigned to the system variable SRCDIR during installation initialization.

## FeatureInitialize Example

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FeatureInitialize function.
*
\*-----*/

NUMBER nResult, n;

program

    // Set a target directory.
    TARGETDIR = "C:\\temp" ^ MEDIA;

    // Select features to transfer.
    nResult = FeatureDialog ("", "", TARGETDIR,"");

    if (nResult < 0) then
        sprintfBox (SEVERE, "FeatureDialog ERROR", "%ld", nResult);
    endif;

    // Transfer files associated with data1.cab (Data Media).
    nResult = FeatureMoveData (MEDIA, n, 0);
    if (nResult < 0) then
        sprintfBox (SEVERE, "FeatureMoveData ERROR", "%ld", nResult);
    endif;

    // Set up for second media.
    MEDIA = "second";

    // Set a target directory.
    TARGETDIR = "C:\\temp" ^ MEDIA;

    // Associate new media with second1.cab cab file.
    nResult = FeatureInitialize (MEDIA, "second1.cab");
    if (nResult < 0) then
        sprintfBox (SEVERE, "FeatureInitialize ERROR", "%ld", nResult);
    endif;

    // Select features to transfer.
    nResult = FeatureDialog ("", "", TARGETDIR,"");
    if (nResult < 0) then
        sprintfBox (SEVERE, "FeatureDialog ERROR", "%ld", nResult);
    endif;

    // Reinitialize FeatureMoveData function.
    nResult = FeatureMoveData ("", n ,0);
    if (nResult < 0) then
        sprintfBox (SEVERE, "FeatureMoveData ERROR", "%ld", nResult);
    endif;

    // Transfer files associated with second1.cab (second Media).
    nResult = FeatureMoveData (MEDIA, n, 0);

```

```

    if (nResult < 0) then
        sprintfBox (SEVERE, "FeatureMoveData ERROR", "%ld", nResult);
    endif;

endprogram

// Source file: Is5fn628.rul

```

## FeatureIsItemSelected

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

*Project-specific differences are noted where appropriate.*

In InstallScript projects, **FeatureIsItemSelected** determines the current selection state of the specified feature. In InstallScript MSI projects, **FeatureIsItemSelected** determines the current installed state of the specified feature. You can also use [FeatureGetData](#) to determine if a feature is selected.

**FeatureIsItemSelected** is typically called to perform feature-specific tasks before or after file transfer. To perform feature-specific tasks during file transfer in an InstallScript installation, it is recommended that you place code in feature event handler functions.

### Syntax

```
FeatureIsItemSelected ( szFeatureSource, szFeature );
```

## Parameters

**Table 69** ▪ FeatureIsItemSelected Parameters

| Parameter              | Description                                                                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | In InstallScript projects, specifies the media library for which the installed state or selection setting is determined.<br><br>In InstallScript MSI projects, specifies the media name of the script-created feature set.                   |
| <b>szFeature</b>       | Specifies the name of the feature for which the installed state or selection setting is determined. To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a> . |

## Return Values

**Table 70** ▪ FeatureIsItemSelected Return Values

| Return Value     | Description                                                                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TRUE (1)</b>  | In InstallScript projects, szFeature is selected.<br><br>In InstallScript MSI projects, szFeature's installed state is INSTALLSTATE_LOCAL (feature was installed on the local drive). |
| <b>FALSE (0)</b> | In InstallScript projects, szFeature is deselected.<br><br>In InstallScript MSI projects, szFeature's installed state is INSTALLSTATE_ABSENT (feature was uninstalled).               |
| <b>&lt; 0</b>    | The function failed to determine if the feature was installed or selected. Call <a href="#">FeatureError</a> for additional information.                                              |

## FeatureIsItemSelected Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureIsItemSelected function.
 *
 * This example script displays a dialog that displays a list
 * of features in the setup that the user can install and the
 * amount of space that each feature occupies. When the user
 * selects features, the installed state of the features is
 * provided.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features and/or
 *           subfeatures with components containing files.
```

```

*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

// Include iswi.h for Windows Installer API function prototypes and constants,
// and to declare code for the OnBegin and OnEnd events.
#include "iswi.h"

// The keyword export identifies MyFunction() as an entry-point function.
// The argument it accepts must be a handle to the Installer database.
export prototype MyFunction(HWND);

// To Do: Declare global variables, define constants, and prototype user-
// defined and DLL functions here.

function MyFunction(hMSI)

    STRING  szTitle, szMsg, svDir;
    NUMBER  nResult;

begin

end;

```

## FeatureListItems

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureListItems** function lists all subfeatures under the feature specified in `szFeature`. The list of fully qualified subfeature names is stored in `listFeatures`. If `szFeature` has subfeatures, `listFeatures` returns an empty list.

## Syntax

```
FeatureListItems ( szFeatureSource, szFeature, listFeatures );
```

## Parameters

**Table 71** • FeatureListItems Parameters

| Parameter              | Description                                                                                                                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the script-created feature set whose subfeatures are listed.                                                                                                                                                                               |
| <b>szFeature</b>       | Specifies the feature whose subfeatures are listed. Pass a null string ("") in this parameter to list all top-level features. To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a> . |
| <b>listFeatures</b>    | Returns the list of features. You must call <a href="#">ListCreate</a> before calling FeatureListItems to initialize the string list identified by listFeatures.                                                                                                       |

## Return Values

**Table 72** • FeatureListItems Return Values

| Return Value  | Description                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | FeatureListItems listed the features.                                                                           |
| <b>&lt; 0</b> | FeatureListItems was unable to list the features. Call <a href="#">FeatureError</a> for additional information. |

## FeatureListItems Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureListItems function.
 *
 * This example script demonstrates a function that lists all
 * subfeatures under a specified feature.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features and/or
 *           subfeatures with components containing files.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"
```

```

// Include iswi.h for Windows Installer API function prototypes and constants,
// and to declare code for the OnBegin and OnEnd events.
#include "iswi.h"

// The keyword export identifies MyFunction() as an entry-point function.
// The argument it accepts must be a handle to the Installer database.
export prototype MyFunction(HWND);

// To Do: Declare global variables, define constants, and prototype user-
// defined and DLL functions here.

function MyFunction(hMSI)

    STRING  szTitle, szMsg;
    NUMBERlistID;

begin

    szTitle = "List MEDIA Features";
    szMsg   = "MEDIA contains the following top-level features:";

    // Initialize the string list.
    listID = ListCreate (STRINGLIST);

    // Create a list of top-level features in the specified media.
    FeatureListItems (MEDIA, "", listID);

    // Display the list of top-level features.
    SdShowInfoList (szTitle, szMsg, listID);

end;

```

## FeatureLoadTarget

---

**Project** ▪ This information applies to InstallScript projects.

The **FeatureLoadTarget** function is called automatically during the initialization of any installation for which a valid log file exists.

### Syntax

```
FeatureLoadTarget( szReserved );
```

## Parameters

**Table 73** • FeatureLoadTarget Parameters

| Parameter         | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| <b>szReserved</b> | Pass a null string ("" ) in this parameter. No other value is allowed. |

## Return Values

**Table 74** • FeatureLoadTarget Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| <b>0</b>     | This function always returns zero (0). |

## Additional Information

FeatureLoadTarget reads the log file and retrieves the target directory of all filegroups in the setup. FeatureLoadTarget retrieves the values of all text substitutions used by the setup; this includes the target directory of all filegroups and the value of all target-directory-related system variables, as well as all other text substitution values.

# FeatureMoveData

**Project** • This information applies to InstallScript projects:

The **FeatureMoveData** function transfers and decompresses files associated with selected features in the file media referenced by szFeatureSource. The function automatically prompts the end user for the next disk when it is needed.

If you use this function to transfer files to [WINSYSDIR64](#), you must first disable file system redirection using [WOW64FSREDIRECTION](#). Otherwise, files being transferred to WINSYSDIR64 are incorrectly redirected to the 32-bit SysWOW64 folder. Since some Windows functionality that could be used by the installation requires that redirection be enabled to work, Windows documentation recommends that you disable redirection only for as long as necessary. It is recommended that you then enable file system redirection as soon as you have completed transferring the necessary files to WINSYSDIR64. To learn more, see [Targeting 64-Bit Operating Systems with InstallScript Installations](#).

When you call FeatureMoveData, Do (SELFREGISTRATIONPROCESS) is called automatically after the files are installed but before the call returns. Therefore, if your installation needs to perform additional actions after the file transfer but before self-registration, place these actions in the OnMoved event; the OnMoved event is called after the file transfer but before the batch self-registration occurs.

You can call FeatureMoveData more than once on the same media, but you must reset internal structures before the second and subsequent calls by calling FeatureMoveData with a null string ("" ) in the first parameter position. InstallShield automatically initializes the default media and internal structures before your first call to FeatureMoveData.

**Note** ▪ This function cannot be used with script-created feature sets.

Syntax

FeatureMoveData ( szFeatureSource, nvReserved, nReserved );

Parameters

Table 75 ▪ FeatureMoveData Parameters

| Parameter       | Description                                                                   |
|-----------------|-------------------------------------------------------------------------------|
| szFeatureSource | Specifies the media name of the file media whose files are to be transferred. |
| nvReserved      | Pass a number variable in this argument. No useful data is returned.          |
| nReserved       | Pass zero in this parameter. No other value is allowed.                       |

Return Values

Table 76 ▪ FeatureMoveData Return Values

| Return Value | Description                                                                           |
|--------------|---------------------------------------------------------------------------------------|
| 0            | FeatureMoveData was successful.                                                       |
| < 0          | FeatureMoveData failed. Call <a href="#">FeatureError</a> for additional information. |

FeatureMoveData Example

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the functions SdSetupTypeEx, SdFeatureDialog,
* FeatureMoveData, FeatureError, and PlaceWindow.
*
* Notes: To run this example script, create a project with
*        the following features (f), subfeatures (sf),
*        and components (c):
*
*        (f) Program_Files
*            (c) Program_DLLS
*            (c) Program_EXEs
*        (f) Example_Files
*            (sf) Small_Documents
*                (c) Small_Document_Examples
*            (sf) Books
*                (c) Book_Examples
*            (sf) Graphics
```

```

*           (c) Graphic_Examples
*       (f) Help_Files

end;

```

# FeaturePatch

**Project** ▪ This information applies to InstallScript projects.

The **FeaturePatch** function is called only in installations that use differential media. (You can check the media format by calling **MediaGetData** with MEDIA\_FIELD\_MEDIA\_FLAGS as its second argument).

**FeaturePatch** causes the next call to **FeatureTransferData** or **FeatureMoveData** to reinstall all features that are already installed when **FeatureTransferData** is called, including all of the maintenance/uninstallation feature's files except for Data1.hdr, Data1.cab, and Layout.bin. (Note that the maintenance/uninstallation feature is automatically placed in your disk image by the release builder and is not displayed in InstallShield.) A copy of the running file media library is stored on the target machine for use during subsequent maintenance operations, that is, modifying, repairing, or uninstalling.

## Syntax

```
FeaturePatch ( );
```

## Parameters

None.

## Return Values

**Table 77** ▪ FeaturePatch Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| 0            | Indicates that the function succeeded. |
| < 0          | Indicates that the function failed.    |

## Additional Information

**FeaturePatch** is called in the default code for the OnUpdateUIBefore event handler function.

# FeatureReinstall

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

In a setup that has already been run, after the **FeatureReinstall** function is called, the next call to **FeatureTransferData** performs the file transfer that was specified the last time the setup was run.

## Syntax

```
FeatureReinstall ( );
```

## Parameters

None

## Return Values

**Table 78** • FeatureReinstall Return Values

| Return Value | Description                                                                     |
|--------------|---------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully prepared the setup for reinstallation. |
| < 0          | Indicates that the function was unable to prepare the setup for reinstallation. |

# FeatureRemoveAll

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

**FeatureRemoveAll** is used during a maintenance install to force the removal of all features that were installed previously. FeatureRemoveAll is generally called when the user selects the Remove option in the [SdWelcomeMaint](#) dialog.

Calling FeatureRemoveAll causes all features to be deselected. As a result, when [FeatureTransferData](#) is called, any features that have already been installed (determined by reading the setup log file, if it exists) are removed (uninstalled).

Setup determines whether or not features have been previously installed by reading the setup log file. If no valid log file is found during setup initialization, all features are considered *not installed*. In this case, calling **FeatureRemoveAll** clears all feature selections, but does not force uninstallation of the features when **FeatureTransferData** is called.

**Note** • **FeatureRemoveAll** also deselects all internal features, including the features containing the Disk 1 setup files that are automatically installed to the DISK1TARGET location.

## Syntax

```
FeatureRemoveAll ( );
```

## Parameters

None

## Return Values

**Table 79** ▪ FeatureRemoveAll Return Values

| Return Value | Description                                                                 |
|--------------|-----------------------------------------------------------------------------|
| 0            | Indicates that the function successfully deselected all feature selections. |
| < 0          | Indicates that the function was unable to deselect all feature selections.  |

## FeatureRemoveAllInLogOnly

**Project** ▪ This information applies to InstallScript projects.

The **FeatureRemoveAllInLogOnly** function is called during an update installation to force the removal of all features that are not in the current media but were installed previously, as recorded in the setup log file.

### Syntax

```
FeatureRemoveAllInLogOnly ( );
```

### Parameters

None.

## Return Values

**Table 80** ▪ FeatureRemoveAllInLogOnly Return Values

| Return Value | Description                                                                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully deselected the feature selections.                                                                                                                                                                            |
| < 0          | Indicates that the function was unable to deselect the feature selections.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

### Additional Information

Calling **FeatureRemoveAllInLogOnly** causes all features that are not in the current media but were installed previously to be deselected. As a result, when [FeatureTransferData](#) is called, those features will be removed (uninstalled).

**Caution** ▪ Do not call **FeatureRemoveAllInLogOnly** in an "add-on" installation—that is, an installation with the same **INSTANCE\_GUID** as a application already on the system that includes a subset of the features in the earlier

*installation. The result would be the uninstallation (removal) of all features that were contained in the earlier installation, but not the features in the current installation.*

If no valid log file is found during installation initialization, calling `FeatureRemoveAllInLogOnly` has no effect.

## FeatureRemoveAllInMedia

**Project** - This information applies to *InstallScript* projects.

The **FeatureRemoveAllInMedia** is used during a maintenance installation to force the removal of all features that are in the current media and were installed previously. This function is generally called when the user selects the Remove option in the `SdWelcomeMaint` dialog.

When you call `FeatureRemoveAllInMedia`, only the features listed in the media header are removed; however, in the case of an updated application in which features were removed but not uninstalled during the update—that is, the features did not exist in the update media but did exist in the original media (and the update did not call `FeatureRemoveAllInLogOnly`)—whether or not these features are removed during uninstallation depends on whether the application was updated via a differential media or a full update media:

- If the application was updated via a full media, the full media header replaces the original media header; therefore, these features are not removed during uninstallation.
- If the application was updated via a differential media, both header files are present; therefore, `FeatureRemoveAllInMedia` removes these features.

To ensure that all installed features are uninstalled, an installation should call `FeatureRemoveAllInMediaAndLog`. This ensures that all features are removed.

### Syntax

```
FeatureRemoveAllInMedia ( );
```

### Parameters

None.

## Return Values

**Table 81** • FeatureRemoveAllInMedia Return Values

| Return Value | Description                                                                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully deselected all feature selections.                                                                                                                                                                            |
| < 0          | Indicates that the function was unable to deselect all feature selections.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

Calling **FeatureRemoveAllInMedia** causes all features that are in the current media to be deselected. As a result, when **FeatureTransferData** is called, any features that have already been installed (determined by reading the installation log file, if it exists) are removed (uninstalled).

The installation determines whether or not features have been previously installed by reading the installation log file. If no valid log file is found during installation initialization (MAINTENANCE is FALSE), all features are considered *not installed*. In this case, calling **FeatureRemoveAllInMedia** causes all features to be deselected and not installed. However, a subsequent call to **FeatureTransferData** does not uninstall anything (since the log file contains the information regarding what to uninstall). Calling **FeatureRemoveAllInMedia** in this case is not recommended.

**Note** • **FeatureRemoveAll** also deselects all internal features, including the maintenance/uninstallation feature.

# FeatureRemoveAllInMediaAndLog

**Project** • This information applies to *InstallScript* projects.

The **FeatureRemoveAllInMediaAndLog** function is called during an update installation to force the removal of all features that were installed previously—both those that are in the current media, and those that are not in the current media but are recorded in the setup log file.

## Syntax

```
FeatureRemoveAllInMediaAndLog ( );
```

## Parameters

None.

## Return Values

**Table 82** • FeatureRemoveAllInMediaAndLog Return Values

| Return Value | Description                                                                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully deselected all feature selections.                                                                                                                                                                            |
| < 0          | Indicates that the function was unable to deselect all feature selections.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

Calling **FeatureRemoveAllInMediaAndLog** is equivalent to calling both [FeatureRemoveAllInMedia](#) and [FeatureRemoveAllInLogOnly](#).

Calling **FeatureRemoveAllInMediaAndLog** causes all features that were installed previously to be deselected. As a result, when [FeatureTransferData](#) is called, those features will be removed (uninstalled).

The installation determines whether or not features have been previously installed by reading the setup log file. If no valid log file is found during installation initialization ([MAINTENANCE](#) is FALSE), all features are considered *not installed*. In this case, calling **FeatureRemoveAllInMediaAndLog** will cause all features to be deselected and not installed. However, a subsequent call to **FeatureTransferData** will not uninstall anything (since the log file contains the information regarding what to uninstall). Calling **FeatureRemoveAllInMediaAndLog** in this case is not recommended.

**Note** • *FeatureRemoveAllInMediaAndLog will also deselect all internal features, including the maintenance/uninstallation feature.*

# FeatureSaveTarget

**Project** • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

**FeatureSaveTarget** gets the current values of all text substitutions used by the setup project and stores them in the installation log file. This includes the current target directory of all components and the value of all target-directory-related system variables, as well as all other text substitution values.

When the setup initializes and a valid log file is found, any values previously stored with this function are automatically restored. This allows a maintenance setup to update previously installed components and install new components to the appropriate location.

## Syntax

```
FeatureSaveTarget ( szReserved );
```

## Parameters

**Table 83** ▪ FeatureSaveTarget Parameters

| Parameter         | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| <b>szReserved</b> | Pass a null string ("" ) in this parameter. No other value is allowed. |

## Return Values

This function always returns zero (0).

# FeatureSelectItem

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureSelectItem** function sets a feature's selection status to either selected or not selected. You can use **FeatureSelectItem** to change selection status before displaying features in feature dialogs, and you can use it to change or override selections afterward, depending on your installation's requirements.

**Note** ▪ If you call a setup type selection function (such as **FeatureSetupTypeSet**, **SetupType2**, **SdSetupType**, or **SdSetupTypeEx**) after calling **FeatureSelectItem**, the feature selections set by **FeatureSelectItem** are overridden by the selections in the setup type. (This applies to features that you add to your installation project and does not affect internal features.) Be aware that **SetupType2** is called in the default code for the *OnFirstUIBefore* event handler function, which is called after the *OnBegin*, *OnCCPSearch*, and *OnAppSearch* event handler functions are called. You can override or customize the *OnFirstUIBefore* event handler.

If you use **FeatureSelectItem** to deselect a feature, note that the same rules that apply to deselecting a feature through the feature dialog apply. That is, a feature cannot be deselected if it is required by a currently selected feature. Therefore, to deselect a feature that is required by another feature, ensure to deselect the requiring feature before attempting to deselect the required feature.

- It is usually not necessary to call **FeatureSelectItem** during maintenance mode, since the previous feature selections are automatically loaded from the existing log file.

## Syntax

```
FeatureSelectItem ( szFeatureSource, szFeature, bSelect );
```

## Parameters

**Table 84** • FeatureSelectItem Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the script-created feature set or (in InstallScript projects) file media library containing the feature whose selection status is to be set.                                                                                                                                                                                                                                                                 |
| <b>szFeature</b>       | <p>Specifies the feature whose selection status is to be set.</p> <p>You can specify a null string ("") for this parameter. If you specify a null string, all features from szFeatureSource are either selected or deselected, depending on the value of bSelect.</p> <p>For more information about specifying features and subfeatures in InstallScript, see <a href="#">Specifying Features and Subfeatures in Function Calls</a>.</p> |
| <b>bSelect</b>         | <p>Specifies whether the feature should be selected. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Select the specified feature.</li> <li>● <b>FALSE</b>—Do not select the specified feature.</li> </ul>                                                                                                                                                    |

## Return Values

**Table 85** • FeatureSelectItem Return Values

| Return Value  | Description                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | <b>FeatureSelectItem</b> successfully set the feature's selection status.                                                                  |
| <b>&lt; 0</b> | <b>FeatureSelectItem</b> was unable to set the feature's selection status. For additional information, call <a href="#">FeatureError</a> . |

## FeatureSelectItem Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureSelectItem function.
 *
 * This example script demonstrates a function that sets a
 * feature's status to either selected or not selected.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features and/or
 *           subfeatures with components containing files.
 *
 \*-----*/

```

```

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

// Include iswi.h for Windows Installer API function prototypes and constants,
// and to declare code for the OnBegin and OnEnd events.
#include "iswi.h"

// The keyword export identifies MyFunction() as an entry-point function.
// The argument it accepts must be a handle to the Installer database.
export prototype MyFunction(HWND);

// To Do: Declare global variables, define constants, and prototype user-
// defined and DLL functions here.

function MyFunction(hMSI)

    STRING  svDir, szTitle, szMsg;

begin

    svDir    = INSTALLDIR;
    szTitle = "Select Features";
    szMsg    = "Select the features you want to install on your computer.";

    // Set the selection status of Subfeature2 to not selected.
    FeatureSelectItem (MEDIA, "Feature1\\Subfeature2", FALSE);

    // Display available features.
    SdFeatureTree (szTitle, szMsg, svDir, "", 2);

end;

```

## FeatureSelectNew

**Project** ▪ This information applies to InstallScript projects.

The **FeatureSelectNew** function sets the selection status of all new features to either selected or unselected.

### Syntax

```
FeatureSelectNew (szFeatureSource, bSelect);
```

## Parameters

**Table 86** ▪ FeatureSelectNew Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media library containing the new features whose selection status is to be set. Typically, this argument is set equal to the system variable <b>MEDIA</b> .                                                                                |
| <b>bSelected</b>       | Specifies whether the new features are selected or deselected. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Selects the new features.</li> <li>• <b>FALSE</b>—Deselects the new features.</li> </ul> |

## Return Values

**Table 87** ▪ FeatureSelectNew Return Values

| Parameter     | Description                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | FeatureSelectNew successfully set the new features' selection status.                                                                                                                                                                     |
| <b>&lt; 0</b> | FeatureSelectNew was unable to set the new features' selection status.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <b>FormatMessage</b> . |

## Additional Information

New features are features that exist in the installation's file media library but not in the existing log file. FeatureSelectNew is typically called in an update installation to select new features before displaying features in features dialogs. FeatureSelectNew is called in the default code for the OnUpdateUIBefore event handler function.

**Note** ▪ If you call a setup type selection function after calling FeatureSelectNew, the feature selections set by FeatureSelectNew are overridden by the selections in the setup type.

It is usually unnecessary to call FeatureSelectNew during maintenance mode because the previous feature selections are automatically loaded from the existing log file.

# FeatureSetData

**Project** ▪ This information applies to the following project types:

- *InstallScript*

- *InstallScript MSI*

The **FeatureSetData** function sets properties and data for the specified feature. Most of the settings correspond to the properties in the Features view.

## Syntax

```
FeatureSetData ( szFeatureSource, szFeature, nInfo, nData, szData );
```

## Parameters

**Table 88** • FeatureSetData Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the script-created feature set or (in InstallScript projects) file media library that contains the feature for which properties and data are to be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szFeature</b>       | Specifies the name of the feature. For more information about specifying features and subfeatures in InstallScript, see <a href="#">Specifying Features and Subfeatures in Function Calls</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>nInfo</b>           | <p>Specifies the type of information to be set. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FEATURE_FIELD_DESCRIPTION</b>—This text is displayed in the Description field of selection dialogs.</li> <li>● <b>FEATURE_FIELD_FTPLOCATION</b>—An FTP location.</li> <li>● <b>FEATURE_FIELD_HTTPLOCATION</b>—An HTTP location.</li> <li>● <b>FEATURE_FIELD_STATUS (not for script-created feature sets)</b>—This text is displayed in the progress indicator during file transfer.</li> <li>● <b>FEATURE_FIELD_VISIBLE</b>—Indicates whether or not the feature is visible in a feature selection dialog. The parameter nData can be one of the following:<br/>TRUE: The feature is visible.<br/>FALSE: The feature is not visible.</li> <li>● <b>FEATURE_FIELD_SELECTED</b>—Sets the selection status of the feature. This setting has the same effect as <a href="#">FeatureSelectItem</a>. The parameter nData can be one of the following:<br/>TRUE: Select the feature.<br/>FALSE: Do not select the feature.</li> <li>● <b>FEATURE_FIELD_SIZE (not for file media)</b>—The total original file size for the feature.</li> <li>● <b>FEATURE_FIELD_MISC</b>—Miscellaneous text.</li> <li>● <b>FEATURE_FIELD_DISPLAYNAME (not for object projects)</b>—Indicates the name displayed in feature selection dialogs for the feature specified in szFeature.</li> <li>● <b>FEATURE_FIELD_IMAGE</b>—Overrides a feature's default icon assignment. Pass the index of the icon to display in nData. To specify that no icon should be displayed for the feature, pass -1 in nData.</li> </ul> |
| <b>nData</b>           | Specifies a numeric value to set when the information indicated by nInfo is numeric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>szData</b>          | Specifies a string value to set when the information indicated by nInfo is a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 89** • FeatureSetData Return Values

| Return Value | Description                                                                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | FeatureSetData was successful.                                                                                                                                                                                                                                   |
| < 0          | FeatureSetData failed. Call <a href="#">FeatureError</a> for additional information.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## FeatureSetData Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureSetData function.
 *
 * This example script demonstrates a function that sets data
 * and properties for a specified feature.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features and/or
 *           subfeatures with components containing files.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

// Include iswi.h for Windows Installer API function prototypes and constants,
// and to declare code for the OnBegin and OnEnd events.
#include "iswi.h"

// The keyword export identifies MyFunction() as an entry-point function.
// The argument it accepts must be a handle to the Installer database.
export prototype MyFunction(HWND);

// To Do: Declare global variables, define constants, and prototype user-
//        defined and DLL functions here.

function MyFunction(hMSI)

    STRING  svDir, szTitle, szMsg, szData;
    NUMBER  nData;

begin

    svDir   = INSTALLDIR;
    szTitle = "Select Features";
    szMsg   = "Select the features you want to install on your computer.";

```

```

szData = "Required Feature";

// Hide Feature1 from the end user.
FeatureSetData (MEDIA, "Feature1", FEATURE_FIELD_VISIBLE, FALSE, szData);

// Set the display name for Feature2.
FeatureSetData (MEDIA, "Feature2", FEATURE_FIELD_DISPLAYNAME, nData, szData);

// Display available features.
SdFeatureTree (szTitle, szMsg, svDir, "", 2);

end;

```

## FeatureSetTarget

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureSetTarget** function assigns the value of szLocation to the public property (in InstallScript MSI projects) or property variable (in InstallScript projects) that is specified by szPropertyVar. Properties or property variables can be used in the Destination field of the Components view and in the Target field of a shortcut in the Shortcuts view. Call **FeatureSetTarget** before calling [FeatureMoveData](#).

**Note** ▪ This function cannot be used with script-created feature sets.

This function cannot set the value of an object's property variable. To set the value of an object's property variable, you must use the object's ScriptDefinedVar property; see the object's help page for details. (You can display an object's help page by selecting the object in the Objects view or, if the object is included in your project, the Features or Setup Design view.) For information on adding the ScriptDefinedVar property to an object that you have created, see [Add a ScriptDefinedVar Property to My Object](#).

In InstallScript MSI projects, this function was designed to set paths for public properties that are in the Directory table. You can create a new directory by clicking a component's destination or a shortcut's target, and creating a new directory. This newly created directory has TARGETDIR as its Directory\_Parent. Through script, you can use **FeatureSetTarget** to set this public property (directory).

### Syntax

```
FeatureSetTarget ( szFeatureSource, szPropertyVar, szLocation );
```

## Parameters

**Table 90** • FeatureSetTarget Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media library whose user-defined variable is to be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szPropertyVar</b>   | <p>Specifies the user-defined variable. In InstallShield, user-defined variables take the form &lt;variable name&gt;.</p> <div>  <p><b>Project</b> • (InstallScript MSI only:) The property used in this parameter must be a public property. You do not need to create an entry in the Property Manager for this property. If you intend to use the property as a destination, you must use it as a component's destination, not a feature's destination.</p> </div> |
| <b>szLocation</b>      | Specifies the path expression to substitute for the user-defined variable. This string should not include extra quotation marks, even if it specifies a long path. The value of szLocation can be a complete path—including drive letter and colon—or a partial path, depending on how szPropertyVar is used.                                                                                                                                                                                                                                          |

## Return Values

This function always returns 0.

## FeatureSetTarget Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureSetTarget function. After adding this
 * to a script for an InstallScript project, you will see the
 * modified value of INSTALLDIR in the SdAskDestPath
 * dialog. In a project that had any components with OTHERLOC as
 * their destination, that would also be changed.
 *
 \*-----*/

function OnBegin( )

begin
// change values of directory properties INSTALLDIR and OTHERLOC for a first-time
// installation
if (!MAINTENANCE) then
    FeatureSetTarget(MEDIA, "<INSTALLDIR>", "C:\\RightHere");
    FeatureSetTarget(MEDIA, "<OTHERLOC>", "C:\\SomewhereElse");
endif;

end;

```

# FeatureSetupTypeEnum

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureSetupTypeEnum** function enumerates all setup types associated with the specified media. These setup types are defined by you in the IDE and stored in the file media. You must create the listSetupTypes string list using the [ListCreate](#) function.

**Note** ▪ This function cannot be used with script-created feature sets.

## Syntax

```
FeatureSetupTypeEnum ( szFeatureSource, listSetupTypes );
```

## Parameters

**Table 91** ▪ FeatureSetupTypeEnum Parameters

| Parameter              | Description                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media whose setup types are to be enumerated.                                                                                 |
| <b>listSetupTypes</b>  | Returns a list of all setup types in the specified media. The string list identified by listSetupTypes must already have been initialized by a call to ListCreate. |

## Return Values

**Table 92** ▪ FeatureSetupTypeEnum Return Values

| Return Value  | Description                          |
|---------------|--------------------------------------|
| <b>0</b>      | FeatureSetupTypeEnum was successful. |
| <b>&lt; 0</b> | FeatureSetupTypeEnum failed.         |

## FeatureSetupTypeEnum Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureSetupTypeEnum function,
```

```

*
* This script enumerates the setup types in the media.
*
* Note: To run this example script, create a project (or
*       insert into a project) with several setup types
*       defined. The value of DEFTYPE must be the name
*       of one of your setup types.
*
\*-----*/

#define SDSHOWTITLE "Setup Type Enumeration"
#define SDSHOWMSG   MEDIA + " media's enumerated setup types are:"
#define SETUPTITLE  "Setup Type Selection"
#define SETUPMSG    "Select a setup type."
#define DEFTYPE     "Typical"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FeatureSetupTypeEnum(HWND);

function ExFn_FeatureSetupTypeEnum(hMSI)
    LIST listID;
    STRING svSetupType;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Create a list to store setup types.
    listID = ListCreate ( STRINGLIST );

    // Get the setup type names from the media into the list.
    if (FeatureSetupTypeEnum( MEDIA, listID) < 0 ) then
        MessageBox ("FeatureSetupTypeEnum failed.", WARNING);
    endif;

    // Display the setup types.
    SdShowInfoList (SDSHOWTITLE, SDSHOWMSG, listID);

    // Now show setup types in a selection dialog.
    svSetupType = DEFTYPE;
    SdSetupTypeEx (SETUPTITLE, SETUPMSG, "", svSetupType, 0);

    // Release the list from memory.
    ListDestroy (listID);

end;

```

## FeatureSetupTypeGetData

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureSetupTypeGetData** function retrieves data associated with a specified setup type. You can then use this data for any purpose.

A typical application of FeatureSetupTypeGetData might be to display setup type information in a custom setup type-related dialog. You would call FeatureSetupTypeGetData inside the switch-case statement following the call to [WaitOnDialog](#) that displays the custom dialog.

---

**Note** ▪ *This function cannot be used with script-created feature sets.*

## Syntax

```
FeatureSetupTypeGetData ( szFeatureSource, szSetupType, nInfo, nvResult, svResult );
```

## Parameters

**Table 93** • FeatureSetupTypeGetData Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media from which data associated with a setup type is to be retrieved.                                                                                                                                                                                                                                                                                                                 |
| <b>szSetupType</b>     | Specifies the setup type name. This name must be specified exactly as it appears in the InstallShield interface—for example, “Typical”.                                                                                                                                                                                                                                                                                     |
| <b>nInfo</b>           | Specifies the information to retrieve. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>SETUPTYPE_INFO_DESCRIPTION</b>—Retrieves the description of the specified setup type. The description is returned in svResult.</li> <li>• <b>SETUPTYPE_INFO_DISPLAYNAME</b>—Retrieves the display name of the setup type. The name is returned in svResult.</li> </ul> |
| <b>nvResult</b>        | Returns a NUMBER or LONG value when nInfo specifies information of that type.                                                                                                                                                                                                                                                                                                                                               |
| <b>svResult</b>        | Returns a STRING value when nInfo specifies information of that type.                                                                                                                                                                                                                                                                                                                                                       |

## Return Values

**Table 94** • FeatureSetupTypeGetData Return Values

| Return Value  | Description                                                                   |
|---------------|-------------------------------------------------------------------------------|
| <b>0</b>      | FeatureSetupTypeGetData was successful.                                       |
| <b>&lt; 0</b> | FeatureSetupTypeGetData failed. Call FeatureError for additional information. |

## FeatureSetupTypeGetData Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the functions FeatureSetupTypeGetData,
 * FeatureGetData, FeatureSetData, SdFeatureDialog2,
 * and FeatureSelectItem.
 *
 * Notes: To run this example script, create a project with
 *        the following features (f), subfeatures (sf),
 *        and components (c):
 *
 *        (f) Program_Files

```

```

*           (c) Program_DLLS
*           (c) Program_EXEs
*       (f) Example_Files
*           (sf) Small_Documents
*           (c) Small_Document_Examples
*           (sf) Books
*           (c) Book_Examples
*           (sf) Graphics
*           (c) Graphic_Examples
*       (f) Help_Files
*           (c) Help_Files
*       (f) Utilities
*           (sf) Grammar_Checker
*           (c) Grammar_Checker
*           (sf) Art_Studio
*           (c) Art_Studio
*
* Be sure to enter descriptions into the Description fields of
* the feature properties sheets for the Program_Files and
* Example_Files features and their subfeatures.
*
\*-----*/

## FeatureSetupTypeSet

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureSetupTypeSet** function sets the specified setup type in the file media referenced by `szFeatureSource`. You can use `FeatureSetupTypeSet` to override the selection made in a setup type dialog, such as [SdSetupTypeEx](#).

**Note** ▪ This function cannot be used with script-created feature sets.

## Syntax

```
FeatureSetupTypeSet ( szFeatureSource, szSetupType );
```

## Parameters

**Table 95** • FeatureSetupTypeSet Parameters

| Parameter              | Description                                                               |
|------------------------|---------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media whose setup type is to be set. |
| <b>szSetupType</b>     | Specifies which setup type to set.                                        |

## Return Values

**Table 96** • FeatureSetupTypeSet Return Values

| Return Value  | Description                         |
|---------------|-------------------------------------|
| <b>0</b>      | FeatureSetupTypeSet was successful. |
| <b>&lt; 0</b> | FeatureSetupTypeSet failed.         |

## FeatureSetupTypeSet Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureSetupTypeSet function.
 *
 * Note: To run this example script, create a project (or
 *       insert into a project) with several setup types and
 *       features. Make sure you specify the setup types'
 *       default feature selections. If you do not include
 *       a Compact setup type, then define one of your setup
 *       types as SETUP_TYPE in the #define SETUP_TYPE line
 *       below.
 *
 *-----*/

#define SETUP_TYPE    "Compact"
#define SDSETUPTITLE "Setup Type Selection"
#define SDSETUPMSG    "Select a setup type other than " + SETUP_TYPE + "."
#define SDFEATTITLE   "Feature Selection"
#define SDFEATMSG1    "Feature selection before FeatureSetupTypeSet."
#define SDFEATMSG2    "Feature selection after FeatureSetupTypeSet."
#define MSG1          "FeatureSetupTypeSet will now select all\n"
#define MSG2          "features in the " + SETUP_TYPE + " setup type."
```

```
// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FeatureSetupTypeSet(HWND);

function ExFn_FeatureSetupTypeSet(hMSI)
    STRING szSetupType, svSetup, svDir;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Select a setup type other than SETUP_TYPE to show default
    // selection settings.
    SdSetupTypeEx (SDSETUPTITLE, SDSETUPMSG, "", svSetup, 0);

    // Display the feature selections for the selected setup type.
    svDir = INSTALLDIR;
    SdFeatureMult (SDFEATTITLE, SDFEATMSG1, svDir, "");

    MessageBox (MSG1 + MSG2, INFORMATION);

    // Now change/override the previous setup type selection by
    // selecting SETUP_TYPE's features. All others are deselected.
    szSetupType = SETUP_TYPE;
    if (FeatureSetupTypeSet (MEDIA, szSetupType) < 0) then
        MessageBox ("FeatureSetupTypeSet failed.", SEVERE);
    endif;

    // Display the new feature selections.
    SdFeatureMult (SDFEATTITLE, SDFEATMSG2, svDir, "");

end;
```

## FeatureSpendCost

**Project** ▪ This information applies to InstallScript projects:

The **FeatureSpendCost** function tells the setup that the progress bar should be updated for a certain amount of cost that has been spent by an event external to the setup. This function has the effect of updating the progress bar appropriately as if the setup itself had spent the corresponding amount of cost. This function can only be called during a standard file operation event, such as an event resulting from calling **FeatureTransferData** or **FeatureMoveData**. Typically, this function is called during the OnInstalling or OnInstalled event as a result of an external event occurring that spends cost.

**Note** ▪ It is not necessary to call this function for file transfer operations that the setup engine carries out, such as **XCopyFile** or **CopyFile**. These mechanisms automatically update the status bar during operation. However, **FeatureAddCost** must be called in this case (before file transfer operations begin) so the installation is aware of the additional cost.

## Syntax

```
FeatureSpendCost ( nCostHigh, nCostLow );
```

## Parameters

**Table 97** ▪ FeatureSpendCost Parameters

| Parameter        | Description                                                                |
|------------------|----------------------------------------------------------------------------|
| <b>nCostHigh</b> | Specifies the upper 31 bits of the installation cost that should be spent. |
| <b>nCostLow</b>  | Specifies the lower 31 bits of the installation cost that should be spent. |

## Return Values

**Table 98** ▪ FeatureSpendCost Return Values

| Return Value              | Description                                                        |
|---------------------------|--------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function successfully updated the progress bar. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was unable to update the progress bar. |

# FeatureSpendUninstallCost

**Project** ▪ This function applies to InstallScript projects.

The **FeatureSpendUninstallCost** function is used to tell the setup that the progress bar should be updated for a certain amount of uninstall 'cost' that has been spent by an event external to the setup. This function has the effect of updating the progress bar appropriately as if the setup itself had spent the corresponding amount of cost. This function can only be called during a standard file operation event, such as an event resulting from calling **FeatureTransferData** or **FeatureMoveData**. Typically, this function is called during the OnInstalling or OnInstalled event as a result of an external event occurring that spends cost.

**Note** ▪ It is not necessary to call this function for file transfer operations that are listed in the uninstall log file., such as **XCopyFile** or **CopyFile** operations. The status bar is updated automatically for items listed in the log file, note also that you do not need to call **FeatureAddUninstallCost** for items listed in the log file, as the setup automatically accounts for all items listed in the log file. However, **FeatureAddCost** must be called in this case so the file transfer operation is aware of the additional cost.

## Syntax

```
FeatureSpendUninstallCost ( nOps, nOpType);
```

## Parameters

**Table 99** ▪ FeatureSpendUninstallCost Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>nOps</b>    | The number of operations to spend.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>nOpType</b> | <p>Indicates the type of operation. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>FEATURE_OPCOST_UNINSTALL_FILE</b>—Specifies the operation as uninstalling a file. You can also specify this constant using the value 4096. This enables you to experiment with different sizes to determine what size to use for your custom operation.</li> <li>• <b>FEATURE_OPCOST_UNINSTALL_REGORINI</b>—Specifies the operation as uninstalling a registry file. You can also specify this constant using the value 2048. This enables you to experiment with different sizes to determine what size to use for your custom operation.</li> <li>• <b>FEATURE_OPCOST_UNINSTALL_UNREGFILE</b>—Specifies the operation as unregistering a file. You can also specify this constant using the value 16384. This enables you to experiment with different sizes to determine what size to use for your custom operation.</li> </ul> <p> <b>Note</b> ▪ You can also pass a numeric value in this parameter to indicate an operation of a specific cost. You may need to experiment with different values to determine the appropriate value for a specified custom operation. Note that the total uninstall cost added is nOps multiplied by nOpType.</p> |

## Return Values

**Table 100** ▪ FeatureSpendUninstallCost Parameters

| Return Value              | Description                                                        |
|---------------------------|--------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function successfully updated the progress bar. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was unable to update the progress bar. |

# FeatureStandardSetupTypeSet

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **FeatureStandardSetupTypeSet** function sets the current setup type to the standard setup type specified by `nSetupType`. This function attempts to set the setup type by calling the `FeatureSetupTypeSet` function with the appropriate string to set the setup type.

## Syntax

```
FeatureStandardSetupTypeSet ( szFeatureSource, nSetupType );
```

## Parameters

**Table 101** ▪ FeatureStandardSetupTypeSet Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media whose setup type is to be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>nSetupType</b>      | <p>Specifies which setup type to set. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• TYPICAL</li> <li>• COMPLETE</li> <li>• COMPACT</li> <li>• CUSTOM</li> </ul> <p>You can customize the string setup type value associated with each numeric constant by customizing the global predefined script variables listed below. The function sets the setup or installation type by trying the appropriate script variable, then tries the setup type name in English and Japanese (see below). Also, when the COMPLETE setup type is specified, the function tries all TYPICAL values after checking the values for COMPLETE. If the setup type cannot be set to any of these values, the function returns failure. The following global predefined script variables can be customized:</p> <ul style="list-style-type: none"> <li>• <b>SETUPTYPE_STR_TYPICAL</b>—Defines the setup type that will be set by default if TYPICAL is specified.</li> <li>• <b>SETUPTYPE_STR_COMPLETE</b>—Defines the setup type that will be set by default if COMPLETE is specified.</li> <li>• <b>SETUPTYPE_STR_COMPACT</b>—Defines the setup type that will be set by default if COMPACT is specified.</li> <li>• <b>SETUPTYPE_STR_CUSTOM</b>—Defines the setup type that will be set by default if CUSTOM is specified.</li> </ul> |

The following table shows the values the FeatureStandardSetupTypeSet function uses when each constant is specified in the nSetupType parameter.

**Table 102** ▪ nSetupType Constants

| Constant        | Strings Used                       |
|-----------------|------------------------------------|
| <b>TYPICAL</b>  | SETUPTYPE_STR_TYPICAL<br>Typical   |
| <b>COMPLETE</b> | SETUPTYPE_STR_COMPLETE<br>Complete |

**Table 102** ▪ nSetupType Constants (cont.)

| Constant       | Strings Used                     |
|----------------|----------------------------------|
| <b>COMPACT</b> | SETUPTYPE_STR_COMPACT<br>Compact |
| <b>CUSTOM</b>  | SETUPTYPE_STR_CUSTOM<br>Custom   |

## Return Values

**Table 103** ▪ FeatureStandardSetupTypeSet Return Values

| Return Value               | Description                                                             |
|----------------------------|-------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | FeatureStandardSetupTypeSet was able to set the specified setup type.   |
| <b>&lt; ISERR_SUCCESS</b>  | FeatureStandardSetupTypeSet was unable to set the specified setup type. |

# FeatureTotalSize

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **FeatureTotalSize** function returns the total size—in bytes—of the features referenced by szFeature.

- To include subfeatures in the size calculation, set bIncludeSubcomp to TRUE.
- To get the total size of all the features in the specified media, set szFeature to a null string ("" ) and set bIncludeSubcomp to TRUE.

**Note** ▪ There might be a difference between the value returned by FeatureTotalSize and the space required values displayed in the SdFeatureDialog, SdFeatureDialog2, SdFeatureDialogAdv, and SdFeatureMult dialogs. This difference is due to the fact that this function does not take into account whether any components associated with the feature are currently filtered by operating system or language, or the cluster size on the target drive. To obtain a drive space calculation that takes these factors into account, call FeatureGetCost.

## Syntax

```
FeatureTotalSize ( szFeatureSource, szFeature, bIncludeSubcomp, bTargetSize );
```

## Parameters

**Table 104** ▪ FeatureTotalSize Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the name of the file media from which the total size of selected features is to be returned.                                                                                                                                                                                                                                      |
| <b>szFeature</b>       | Specifies the name of the feature whose size is to be retrieved. To retrieve the size of the entire media, pass a null string ("") in this parameter.                                                                                                                                                                                       |
| <b>bIncludeSubcomp</b> | Indicates whether to include selected subfeatures of szFeature. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Include selected subfeatures in the size calculation.</li> <li>● <b>FALSE</b>—Do not include subfeatures in the size calculation.</li> </ul>         |
| <b>bTargetSize</b>     | Indicates whether to retrieve the original, uncompressed size or the size in the media library. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Retrieve the original, uncompressed size.</li> <li>● <b>FALSE</b>—Retrieve the size in the media library.</li> </ul> |

## Return Values

**Table 105** ▪ FeatureTotalSize Return Values

| Return Value  | Description                                                                   |
|---------------|-------------------------------------------------------------------------------|
| <b>XXXX</b>   | The total size, in bytes, of the selected features.                           |
| <b>&lt; 0</b> | FeatureTotalSize failed. Call <b>FeatureError</b> for additional information. |

## FeatureTotalSize Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the FeatureListItems, SdFeatureMult, and
 * FeatureTotalSize functions.
 *
 * Comments: To run this example script, create a project with
 *           the following features (f), subfeatures (sf),
 *           and components (c):
 *
 *           (f) Program_Files
 *              (c) Program_DLLS
 *              (c) Program_EXEs
 *           (f) Example_Files

```

```

*           (sf) Small_Documents
*           (c) Small_Document_Examples
*           (sf) Books
*           (c) Book_Examples
*           (sf) Graphics
*           (c) Graphic_Examples
*       (f) Help_Files
*           (c) Help_Files
*       (f) Utilities
*           (sf) Grammar_Checker
*           (c) Grammar_Checker
*           (sf) Art_Studio
*           (c) Art_Studio
*
\*-----*/

#define FEAT_SELECT_TITLE    "Select Features"
#define FEAT_SELECT_MSG     "Select features and subfeatures to install."
#define FEATTOTSIZEMSG1     "Want to change feature selections and see\n"
#define FEATTOTSIZEMSG2     "size change reflected in FeatureTotalSize call?"

    nDone = AskYesNo (FEATTOTSIZMSG1 + FEATTOTSIZMSG2, YES);
endwhile;

ListDestroy (listComplList);

end;

```

## FeatureTransferData

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI—if the InstallScript user interface (UI) style is the traditional style (which uses the InstallScript engine as an external UI handler)*

*This information does not apply to InstallScript MSI projects in which the InstallScript UI style is the new style (which uses the InstallScript engine as an embedded UI handler). To learn more, see [Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations](#).*

If you use an event-based script, the **FeatureTransferData** function is called automatically after the OnFirstUIBefore event and interacts with the OnMoving, OnMoved, and feature events. FeatureTransferData installs or uninstalls features appropriately based on their selection state and whether they are currently installed.

**FeatureTransferData** does the following:

- **FeatureTransferData** installs features that are selected (for example, by end user selections in feature or setup type dialogs) and are currently not installed.
- **FeatureTransferData** uninstalls features that are not selected and are currently installed.

The installation determines whether a feature is currently installed by reading the existing log file during installation initialization. If no valid log file is found during installation initialization, all features are considered to be not installed.

When you call **FeatureTransferData**, Do(SELFREGISTRATIONPROCESS); is called automatically after the files are installed but before the call returns. Therefore, if your installation needs to perform additional actions after the file transfer but before self-registration, place these actions in the OnMoved event; the OnMoved event is called after the file transfer but before the batch self-registration occurs.

## Syntax

```
FeatureTransferData ( szFeatureSource );
```

## Parameters

**Table 106** ▪ FeatureTransferData Parameters

| Parameter              | Description                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFeatureSource</b> | Specifies the media name of the file media whose features have been specified for installation and uninstallation. Typically, you would pass the system variable <b>MEDIA</b> in this parameter. |

## Return Values

**Table 107** ▪ FeatureTransferData Return Values

| Return Value  | Description                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully performed the feature installations and uninstallations. |
| <b>&lt; 0</b> | Indicates that the function could not perform the feature installations and uninstallations.      |

## Additional Information

You can call one of the following functions before calling **FeatureTransferData** to affect the result of the call:

- **FeatureReinstall**—Reinstalls all features that are currently selected when **FeatureTransferData** is called.
- **FeatureRemoveAll**—Removes (uninstalls) all features when **FeatureTransferData** is called.

# FeatureUpdate

**Project** ▪ This information applies to InstallScript project.

The **FeatureUpdate** function causes the next call to **FeatureTransferData** (or **FeatureMoveData**) to reinstall all features that are already installed when FeatureTransferData is called, except the maintenance/uninstallation feature. (Note that this feature is automatically placed in your .cab files by the media builder and is not displayed in InstallShield.)

## Syntax

```
FeatureUpdate ( szReserved );
```

## Parameters

**Table 108** ▪ FeatureUpdate Parameters

| Parameter         | Description                                                            |
|-------------------|------------------------------------------------------------------------|
| <b>szReserved</b> | Pass a null string ("" ) in this parameter. No other value is allowed. |

## Return Values

**Table 109** ▪ FeatureUpdate Return Values

| Return Value  | Description                            |
|---------------|----------------------------------------|
| <b>0</b>      | Indicates that the function succeeded. |
| <b>&lt; 0</b> | Indicates that the function failed.    |

## Additional Information

Call FeatureUpdate in an installation whose maintenance/uninstallation feature you do not want to be used during subsequent maintenance operations (modifying, repairing, or uninstalling). FeatureUpdate is typically called in an update or add-on installation, in which the installation media does not contain all the elements of the previous media and thus should not be used for subsequent maintenance operations.

FeatureUpdate is similar to [FeatureReinstall](#), but FeatureReinstall also reinstalls the maintenance/uninstallation feature.

**Note** ▪ If you call both FeatureUpdate and FeatureReinstall, the call to FeatureUpdate will not have any effect; so if you call FeatureUpdate, do not call FeatureReinstall in the same installation.

Call FeatureUpdate to update only applications that were installed with the same version of InstallShield as the update installation. If you call FeatureUpdate to update an application that was installed with a previous version of InstallShield, the maintenance/uninstallation files will not be updated, so any subsequent maintenance operations will use the maintenance/uninstallation files that were created with the previous version.

The following information applies in this situation: A previously released version of your application was installed by an installation that aborts if a newer version of the application is present. In this case, FeatureUpdate should not be called in an update installation that changes the version number of the installed application. Otherwise, after the update installation runs, the currently installed application cannot be uninstalled.

# FeatureValidate

**Project** ▪ This information applies to InstallScript projects.

**Note** ▪ This function cannot be used with script-created feature sets.

The **FeatureValidate** function validates the password of the file media library or of a specified feature.

## Syntax

```
FeatureValidate ( szMediaLibrary, szFeature, szPassword );
```

## Parameters

**Table 110** ▪ FeatureValidate Parameters

| Parameter             | Description                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------|
| <b>szMediaLibrary</b> | Specifies the name of the file media library whose password is to be validated.                                  |
| <b>szFeature</b>      | Specifies the name of the feature. If this parameter is a null string (""), the entire media library is assumed. |
| <b>szPassword</b>     | Specifies the password to be validated.                                                                          |

## Return Values

**Table 111** ▪ FeatureValidate Return Values

| Return Value  | Description                                                                                                                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | FeatureValidate was successful.                                                                                                                                                                                                                                   |
| <b>&lt; 0</b> | FeatureValidate failed. Call <a href="#">FeatureError</a> for additional information.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## FeatureValidate Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the functions SdSetupTypeEx, SdFeatureDialog,
 * FeatureIsItemSelected, FeatureGetData, and FeatureValidate.
 *
 * Notes: To run this example script, create a project with
 *        the following features (f), subfeatures (sf),
 *        and components (c):
 *
 *          (f) Program Files
 *              (c) Program DLLS
 *              (c) Program EXEs
 *          (f) Example Files
 *              (sf) Small Documents
 *                  (c) Small Document Examples
 *              (sf) Books
```

```

*           (c) Book Examples
*           (sf) Graphics
*           (c) Graphic Examples
*       (f) Help Files
*           (c) Help Files
*       (f) Utilities
*           (sf) Grammar Checker
*           (c) Grammar Checker
*           (sf) Art Studio
*           (c) Art Studio
*       (f) Evaluation Copy
*           (c) Evaluation Copy
*           (c) Help Files
*
* Insert "dummy" files into the components. Make sure you
* define the correct file name for the main EXE (MAIN_EXE,
* below) that you insert into the Program EXEs components.
* Run the setup with and without a password assigned to the
* Program Files feature (remember to rebuild your media
* each time).
*
* You can also create billboards (name them Bbrd1.bmp,
* Bbrd2.bmp, and Bbrd3.bmp) and add them to the project in
* the Support Files/Billboards's Language Independent folder.
*
* This example script installs files, adds an icon to the
* Start Programs menu, and provides uninstallation
* functionality.
*

## FileCompare

The **FileCompare** function compares the size, modify dates, contents, or versions of two files.

### Syntax

```
FileCompare ( szFileName1, szFileName2, nCompareFlag );
```

## Parameters

**Table 112** ▪ FileCompare Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName1</b>  | Specifies the name of the first file to compare. The installation uses the system variable <b>SRCDIR</b> as the path of the file.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szFileName2</b>  | Specifies name of the second file to compare. The installation uses one of the following system variables as the path of the file: <ul style="list-style-type: none"> <li>● <b>TARGETDIR</b> (in an InstallScript installation)</li> <li>● <b>INSTALLDIR</b> (in an Basic MSI or InstallScript MSI installation)</li> </ul>                                                                                                                                                                                                         |
| <b>nCompareFlag</b> | Specifies comparison options. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>COMPARE_SIZE</b>—Compares the size of the two files.</li> <li>● <b>COMPARE_DATE</b>—Compares the modify dates of the two files.</li> <li>● <b>COMPARE_VERSION</b>—Compares the version resource of the two files.</li> <li>● <b>COMPARE_MD5_SIGNATURE</b>—Compares the MD5 signature of the two files. If the MD5 signatures match, the contents of the files are identical.</li> </ul> |

## Return Values (when COMPARE\_MD5\_SIGNATURE is specified)

**Table 113** ▪ FileCompare Return Values (COMPARE MD5\_SIGNATURE)

| Return Value               | Description                                                                                                                                                                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully compared the files, specifically: <ul style="list-style-type: none"> <li>● <b>EQUALS</b>—The files MD5 signatures are the same (the files contents are the same).</li> <li>● <b>NOT_EQUALS</b>—The files MD5 signatures are not the same.</li> </ul> |
| <b>&lt;= ISERR_SUCCESS</b> | The function failed to compare the files.                                                                                                                                                                                                                                      |

## Return Values (when COMPARE\_SIZE, COMPARE\_DATE, or COMPARE\_VERSION is

specified)

**Table 114** ■ FileCompare Return Values (COMPARE\_SIZE, COMPARE\_DATE, or COMPARE\_VERSION)

| Return Value               | Description                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully compared the files, specifically: <ul style="list-style-type: none"> <li>● <b>EQUALS</b>—The first file's date, size, or version is equal to that of the second file.</li> <li>● <b>GREATER_THAN</b>—The first file is newer or larger than the second file.</li> <li>● <b>LESS_THAN</b>—The first file is older or smaller than the second file.</li> </ul> |
| <b>&lt;= ISERR_SUCCESS</b> | The function failed to compare the files.                                                                                                                                                                                                                                                                                                                                              |

## FileCompare Example

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FileCompare function.
*
* This example script calls FileCompare three times:
*
* -- The first call compares the version of FILE_COMP1 in SDIR
*    to the version of FILE_COMP2 in TDIR.
*
* -- The second call checks if FILE_COMP1 was created earlier
*    than FILE_COMP2.
*
* -- The third call checks if FILE_COMP1 is smaller than
*    FILE_COMP2.
*
* Note: Before you run this script, set the preprocessor
*       constants so that they reference existing files in
*       existing directories on the target computer.
*
\*-----*/

            FILE_COMP1, FILE_COMP2);
endswitch;

end;

```

## FileDeleteLine

The **FileDeleteLine** function deletes a range of lines (including the starting line and ending line) from a text file using a starting and ending line number. This function works on line-oriented text files—it does not work with binary files. You can use FileDeleteLine with the FileGrep function to search and delete text lines in a file.

**Caution** ▪ The file specified by *szFileName* must not already have been opened by a call to *OpenFile*. If *szFileName* is already open, call *CloseFile* before calling *FileDeleteLine*.

## Syntax

```
FileDeleteLine ( szFileName, nStartLineNum, nEndLineNum );
```

## Parameters

**Table 115** ▪ FileDeleteLine Parameters

| Parameter            | Description                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>    | Specifies the unqualified name of a file located in the directory specified by the system variable SRCDIR, or the fully qualified path to the file. The lines specified by nStartLineNum and nEndLineNum will be deleted from that file if it exists. |
| <b>nStartLineNum</b> | Specifies the number of the first line to delete from the file. Note that line numbering begins at 0.                                                                                                                                                 |
| <b>nEndLineNum</b>   | Specifies the number of the last line to delete from the file. Note that line numbering begins at 0. To delete from the line specified by nStartLineNum to the end of the file, pass the predefined constant DELETE_EOF in this parameter.            |

## Return Values

**Table 116** ▪ FileDeleteLine Return Values

| Return Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | FileDeleteLine successfully deleted the specified lines from the file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>&lt; 0</b> | FileDeleteLine failed because of one of the following conditions: <ul style="list-style-type: none"> <li>● <b>FILE_NOT_FOUND (-2)</b>—The installation could not find the file in szFileName.</li> <li>● <b>FILE_RD_ONLY (-5)</b>—The file is write-protected.</li> <li>● <b>LINE_NUMBER (-7)</b>—One of the line numbers you specified is less than zero, or the line number does not exist in the file.</li> <li>● <b>OUT_OF_DISK_SPACE (-6)</b>—There is insufficient space on the disk drive to complete the specified operation.</li> <li>● <b>OTHER_FAILURE (-1)</b>—Some other unspecified error has occurred.</li> </ul> |

## FileDeleteLine Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* Demonstrates the FileDeleteLine function.
*
* This script searches a file for the first line that includes
* the string "PATH". If a line with that string is found, it
* is deleted. Finally, a new line is added to the file at the
* position of the deleted line. If a line with the word
* "PATH" was not found, the new line is inserted at the top of
* the file.
*
* Note: Before running this script, create a batch file
*       named ISExempl.bat in the root of drive C. For
*       best effect, that file should include PATH command.
*
\*-----*/

#define SDIR          "C:\\\\"
#define EXAMPLE_BAT  "ISExempl.bat"
#define TITLE        "FileDeleteLine Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FileDeleteLine(HWND);

function ExFn_FileDeleteLine(hMSI)
    STRING szSearchStr, svReturnLine, szNewString, szMsg;
    NUMBER nvResult, nvLineNum;
begin

    // Set up the search string parameter for FileGrep.
    szSearchStr = "PATH";

    // Find the search string in the specified file.
    nvResult = FileGrep (SDIR ^ EXAMPLE_BAT, szSearchStr,
                        svReturnLine, nvLineNum, RESTART);

    switch(nvResult)
    case FILE_NOT_FOUND:
        // Report error; then terminate.
        MessageBox (EXAMPLE_BAT + " not found.", WARNING);
        abort;
    case FILE_LINE_LENGTH:
        // Report error; then terminate.
        MessageBox (EXAMPLE_BAT + "lines too long.", WARNING);
        abort;
    case OTHER_FAILURE:
        // Report error; then terminate.
        MessageBox (EXAMPLE_BAT + "Unknown failure on call to FileGrep.",
                    WARNING);
        abort;
    case END_OF_FILE:
        // Report that the search string was not found.
        szMsg = "\"%s\" not found in %s.";
        sprintfBox (INFORMATION, TITLE, szMsg, szSearchStr, EXAMPLE_BAT);

```

```

        // Set the line number parameter for FileInsertLine.
        nvLineNumber = 0;
    case 0:
        // Delete the line with the search string.
        if (FileDeleteLine (EXAMPLE_BAT, nvLineNumber, nvLineNumber) < 0) then
            MessageBox ("Failed on call to FileDeleteLine.", SEVERE);
            abort;
        else
            // Report the deletion.
            szMsg = "\"%s\" found in line %d of %s:\n\n%s\n\nLine deleted. ";
            sprintfBox (INFORMATION, TITLE, szMsg, szSearchStr, nvLineNumber,
                        EXAMPLE_BAT, svReturnLine);
        endif;
    endswitch;

    // Set up the new string parameter for FileInsertLine.
    szNewString = "PATH=C:\\Windows\\Bin;C:\\Bin;C:\\Ishield;";

    // Insert the new string.
    if (FileInsertLine (EXAMPLE_BAT, szNewString, nvLineNumber, BEFORE) < 0) then
        // Report an error.
        MessageBox ("Failed on call to FileInsertLine.", SEVERE);
    else
        // Report success.
        szMsg = "The following string was inserted as line %d of %s:\n\n %s";
        sprintfBox (INFORMATION, TITLE, szMsg, nvLineNumber, EXAMPLE_BAT,
                    szNewString);
    endif;

end;

```

## FileGrep

The **FileGrep** function searches a text file for a specified string. If the string is found, the line containing that string is returned in `svReturnLine` and the number of the line is returned in `nvLineNumber`. The search is not case-sensitive. FileGrep works on line-oriented text files; it will not work with binary files.

**Note** • It is not necessary to open a file before searching it with FileGrep; nor do you need to close it after the call to FileGrep. File open and file close are performed automatically by FileGrep. Although FileGrep will perform successfully in most cases on a file that is already open as a result of a previous call to `OpenFile`, it will return `FILE_NOT_FOUND` if the file was opened in append mode.

### Syntax

```
FileGrep ( szFileName, szSearchStr, svReturnLine, nvLineNumber, nFlag );
```

## Parameters

**Table 117** ▪ FileGrep Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>   | Specifies the fully qualified name of the file to search.                                                                                                                                                                                                                                                 |
| <b>szSearchStr</b>  | Specifies the search string.                                                                                                                                                                                                                                                                              |
| <b>svReturnLine</b> | Returns the line in which szSearchStr was found.                                                                                                                                                                                                                                                          |
| <b>nvLineNumber</b> | Return the number of the line in which szSearchStr was found. Line numbering starts at 0.                                                                                                                                                                                                                 |
| <b>nFlag</b>        | Specifies search options. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>CONTINUE</b>—Retrieves the next occurrence (if any) of the search string.</li> <li>• <b>RESTART</b>—Retrieves the first instance of the search string.</li> </ul> |

## Return Values

**Table 118** ▪ FileGrep Return Values

| Return Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | FileGrep found the specified string.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>&lt; 0</b> | FileGrep failed because of one of the following conditions: <ul style="list-style-type: none"> <li>• <b>END_OF_FILE (-4)</b>—The end of file was reached without finding the search string.</li> <li>• <b>FILE_NOT_FOUND (-2)</b>—InstallShield was unable to find the file in szFileName.</li> <li>• <b>FILE_LINE_LENGTH (-3)</b>—The line exceeds the maximum length allowed.</li> <li>• <b>OTHER_FAILURE (-1)</b>—An unspecified error has occurred.</li> </ul> |

## FileGrep Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FileGrep function.
*
* FileGrep is called to search a file for the first line that
```

```

* contains the word "PATH". The results are displayed in a
* message box. Note that the FileGrep function is not case
* sensitive.
*
* Note: Before running this script, create a batch file
*       named ISExempl.bat in the root of drive C. For
*       best effect, that file should include PATH command.
*
\*-----*/

#define SOURCE_DIR "C:\\\"
#define SOURCE_FILE "ISExempl.bat"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FileGrep(HWND);

function ExFn_FileGrep(hMSI)
    STRING svLine, szNewString, svReturnLine, szMsg;
    NUMBER nvLineNumber, nvResult;
begin

    // Find the search string in the source file.
    nvResult = FileGrep (SOURCE_DIR ^ SOURCE_FILE, "PATH", svReturnLine,
                        nvLineNumber, RESTART);

    switch(nvResult)
    case FILE_NOT_FOUND:
        // Report error; then abort.
        MessageBox( SOURCE_FILE + " not found.", WARNING);
        abort;
    case FILE_LINE_LENGTH:
        // Report error; then abort.
        MessageBox (SOURCE_FILE + "lines too long.", WARNING);
        abort;
    case OTHER_FAILURE:
        // Report error; then abort.
        MessageBox (SOURCE_FILE + "Unknown failure on call to FileGrep.",
                    WARNING);
        abort;
    endswitch;

    // Loop until end of file.
    while (nvResult != END_OF_FILE)

        // Set up message string for sprintfBox.
        szMsg = "'PATH' found in line %d of %s:\n\n%s'";

        // Report matching line from file.
        sprintfBox (INFORMATION, "FileGrep", szMsg, nvLineNumber, SOURCE_FILE,
                    svReturnLine);

        // Search again.
        nvResult = FileGrep (SOURCE_DIR ^ SOURCE_FILE, "PATH", svReturnLine,
                            nvLineNumber, CONTINUE);

```

```

        endwhile;

    end;

```

## FileInsertLine

The **FileInsertLine** function inserts or replaces a line using line numbers. You can use FileInsertLine with FileGrep, which finds lines and returns their line numbers.

FileInsertLine works on line-oriented text files with lines that are no longer than 1,024 bytes. With InstallShield, a line longer than the maximum allowed length indicates a binary file and causes FileInsertLine to fail.

---

**Caution** ▪ The file specified by *szFileName* must not already have been opened by a call to *OpenFile*. If *szFileName* is already open, call *CloseFile* before calling *FileInsertLine*.

### Syntax

```
FileInsertLine (szFileName, szInsertLine, nLineNumber, nInsertFlag);
```

## Parameters

**Table 119** ▪ FileInsertLine Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>   | Specifies the unqualified name of a file located in the directory specified by the system variable SRCDIR, or the fully qualified path to the file. The value of szInsertLine is inserted into that file if it exists.                                                                                                                                                                                                                                   |
| <b>szInsertLine</b> | Specifies the string to insert into the file.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>nLineNumber</b>  | Specifies the line number at which you want to insert szInsertLine. The first line number is 0.                                                                                                                                                                                                                                                                                                                                                          |
| <b>nInsertFlag</b>  | Specifies an insertion location option. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>BEFORE</b>—Inserts the line before nLineNumber.</li> <li>• <b>AFTER</b>—Inserts the line after nLineNumber.</li> <li>• <b>APPEND</b>—Appends szInsertLine to the line indicated by nLineNumber.</li> <li>• <b>REPLACE</b>—Replaces the line indicated by nLineNumber with szInsertLine.</li> </ul> |

## Return Values

**Table 120** ▪ FileInsertLine Return Values

| Return Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | FileInsertLine successfully inserted the line into the specified file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>&lt; 0</b> | FileInsertLine failed because of one of the following conditions: <ul style="list-style-type: none"> <li>• <b>FILE_LINE_LENGTH (-3)</b>—Indicates that the length of the line exceeds the maximum length allowed for text files.</li> <li>• <b>FILE_NOT_FOUND (-2)</b>—FileInsertLine was unable to find the file in szFileName.</li> <li>• <b>FILE_RD_ONLY (-5)</b>—Indicates that the file is write-protected.</li> <li>• <b>LINE_NUMBER (-7)</b>—Indicates that one of the line numbers you specified is less than zero, or the line number does not exist in the file.</li> <li>• <b>OUT_OF_DISK_SPACE (-6)</b>—Indicates that there is insufficient space on the disk drive to complete the specified operation.</li> <li>• <b>OTHER_FAILURE (-1)</b>—An unspecified error has occurred.</li> </ul> |

## FileInsertLine Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FileInsertLine function.
*
* The AskText dialog is displayed to obtain a line of text
* from the user. This text is then inserted as the first line
* in the text file specified by TARGET_FILE.
*
* FileInsertLine is then called again to append the same text
* to the first line, leaving two copies of the same text in
* the first line of the file.
*
* Note: Before running this script, create a batch file named
*       ISExempl.bat in the root of drive SRCDIR.
*
\*-----*/

#define TARGET_FILE "ISExempl.bat"
#define TITLE       "FileInsertLine Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FileInsertLine(HWND);

function ExFn_FileInsertLine(hMSI)
    STRING szMsg, svText;
begin

    // Set up message parameter for call to AskText.
    szMsg = "Please enter a line to insert into EXAMPLE.BAT.";

    // Get line to add to file.
    AskText (szMsg, "", svText);

    // Insert the text as the first line of the specified file.
    if (FileInsertLine (TARGET_FILE, svText, 0, BEFORE) < 0) then
        MessageBox ("FileInsertLine failed.", SEVERE);
    else
        // Set up message parameter for call to sprintfBox.
        szMsg = "'%s' successfully inserted as first line of %s.";

        // Display message.
        sprintfBox (INFORMATION, TITLE, szMsg, svText, TARGET_FILE);
    endif;

    // Append the same string to the same line.
    if (FileInsertLine(TARGET_FILE, svText, 0, APPEND) < 0) then
        MessageBox("FileInsertLine failed.", SEVERE);

```

```

else
    // Set up message parameter for call to sprintfBox.
    szMsg    = "'%s' successfully appended to first line of %s.";

    // Display message.
    sprintfBox(INFORMATION, TITLE, szMsg, svText, TARGET_FILE);
endif;

end;

```

## FindAllDirs

The **FindAllDirs** function searches an entire hierarchical disk or directory structure starting with the specified directory, and it returns a string list of subdirectory names. You can use FindAllDirs to find either subdirectories of a certain directory, or you can use it to find all the directories on a disk.

If nOp is INCLUDE\_SUBDIR, the search starts at the directory specified by szDir and continues searching the subdirectory structure. If the specified directory is a root directory and nOp contains INCLUDE\_SUBDIR, all the directory names on the entire disk are returned.

### Syntax

```
FindAllDirs ( szDir, nOp, listDirs );
```

## Parameters

**Table 121** ▪ FindAllDirs Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDir</b>    | Specifies the name of the directory to search.<br><br><br><b>Note</b> ▪ If the directory is enclosed in quotation marks, FindAllDirs fails. To ensure that the folder name is not enclosed in quotation marks, call <a href="#">LongPathToQuote</a> (szPath, FALSE) before calling FindAllDirs. |
| <b>nOp</b>      | Specifies whether or not to search all of the subdirectories below szDir. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>EXCLUDE_SUBDIR</b>—Excludes subdirectories.</li> <li>• <b>INCLUDE_SUBDIR</b>—Includes subdirectories.</li> </ul>                                                                         |
| <b>listDirs</b> | Returns a list of fully qualified directory names. The string list identified by listDirs must already have been initialized by a call to <a href="#">ListCreate</a> .                                                                                                                                                                                                           |

## Return Values

**Table 122** ▪ FindAllDirs Return Values

| Return Value  | Description                                                        |
|---------------|--------------------------------------------------------------------|
| <b>0</b>      | FindAllDirs successfully generated the list of subdirectory names. |
| <b>&lt; 0</b> | FindAllDirs function was unable to generate a list.                |

## FindAllDirs Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* This example demonstrates the FindAllDirs function.
*
* FindAllDirs is called to retrieve all directories located
* in a specified directory. Subdirectories are included at
* the user's discretion.
*
\*-----*/
```

```

#define TITLE "FindAllDirs Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FindAllDirs(HWND);

function ExFn_FindAllDirs(hMSI)
    LIST    listDirs;
    STRING  svSearchPath, szMsg;
    NUMBER  nOp, nResult;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Ask the user for a path.
    AskPath ("Enter an existing path.", "", svSearchPath);

    // Ask whether or not to include subdirectories.
    if (AskYesNo ("Include subdirectories?", YES) = YES) then
        nOp    = INCLUDE_SUBDIR;
        szMsg = "Directories and Subdirectories";
    else
        nOp    = EXCLUDE_SUBDIR;
        szMsg = "Directories only";
    endif;

    // Display a message while building the list.
    SdShowMsg ("Searching . . . please wait.", TRUE);

    // Create a STRING list for directory names.
    listDirs = ListCreate (STRINGLIST);

    // Find requested elements place them into the list.
    nResult = FindAllDirs (svSearchPath, nOp, listDirs);

    // Close the message box.
    SdShowMsg ("", FALSE);

    if ( nResult< 0) then
        // Report no matches.
        sprintfBox (INFORMATION, TITLE, "No directories in %s",
                    svSearchPath);
    else
        // Display the list.
        SdShowInfoList (TITLE, szMsg, listDirs);
    endif;
end;

```

# FindAllFiles

The **FindAllFiles** function searches an entire hierarchical subdirectory structure starting with the specified directory, and it returns the name of the first file with a particular file specification. If the specified directory is the root directory, InstallShield searches the entire disk. The function stops at the first matching file name it finds.

**Note** ▪ If the argument passed to *nOp* is *RESET*, InstallShield starts searching at the directory specified in the parameter *szDir* and continues searching the subdirectory structure until it finds a file matching *szFileName*. If *nOp* equals *CONTINUE*, the search continues where it finished the last time the function was called. Call this function repeatedly to find all occurrences of files that match *szFileName*.

The first time you call this function to begin a new search, set *nOp* to *RESET*. You can continue to search for all other occurrences of the specified file by setting *nOp* to *CONTINUE* and placing the function call in a loop that ends when the *FindAllFiles* function fails.

## Finding Files that Match a File Specification

### Task

#### To find all files matching a file specification:

1. Assign to *szDir* the name of the folder to search.
2. Assign to *szFileName* the file specification, such as *IS5\*.txt*.
3. Call **FindAllFiles** with *nOp* set to *RESET*.
4. While the return code from **FindAllFiles** is 0, save the file name in *svResult*; then call **FindAllFiles** with *nOp* set to *CONTINUE*.
5. Call **FindAllFiles** with *nOp* set to *CANCEL*.

**Caution** ▪ You cannot use the *XCopyFile* function within a *FindAllFiles(..., RESET)*, and *FindAllFiles(..., CONTINUE)* loop. If you call *XCopyFile* inside a *FindAllFiles* loop, the file name returned by *FindAllFiles(..., CONTINUE)* may be incorrect.

## Syntax

```
FindAllFiles ( szDir, szFileName, svResult, nOp );
```

## Parameters

**Table 123** ▪ FindAllFiles Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDir</b>      | Specifies the name of the directory to search.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szFileName</b> | Specifies the file specification to search for. Wild-card characters are allowed in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>svResult</b>   | Returns the fully qualified name of the first matching file if found. If <b>FindAllFiles</b> fails, svResult remains unchanged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>nOp</b>        | Indicates search options. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>CONTINUE</b>—Resumes the search at the location where the previous search stopped.</li> <li>● <b>RESET</b>—Starts the search at the beginning of the directory specified by szDir.</li> <li>● <b>CANCEL</b>—Frees all files and folders that were accessed by previous calls to <b>FindAllFiles</b>. Call <b>FindAllFiles</b> with this parameter to ensure the success of subsequent file and folder operations on files and folders that have been accessed by <b>FindAllFiles</b>.</li> </ul> |

## Return Values

**Table 124** ▪ FindAllFiles Return Values

| Return Value  | Description                                                                               |
|---------------|-------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function retrieved and returned a file that matched the specification. |
| <b>&lt; 0</b> | Indicates that the function was unable to find a file that matched the specifications.    |

## FindAllFiles Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FindAllFiles function.
*
* This script gets a directory name and filespec from the
* user. Then it calls FindAllFiles repeatedly to build a
```

```

* list of files that are located in the specified directory
* and whose names match the filespec. Finally, the list of
* matching files is displayed in a listbox.
*
\*-----*/

#define TITLE_TEXT "FindAllFiles Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FindAllFiles(HWND);

function ExFn_FindAllFiles(hMSI)
    STRING szMsg, svDir, svFileSpec, svMatchingFileName, svNumFiles;
    NUMBER nResult, nNumFiles;
    LIST listFiles;
begin

selectdir:

    // Set up parameters for call to SelectDir.
    szMsg = "Select a directory to search.";
    svDir = "";

    // Select a search directory.
    SelectDir (TITLE_TEXT, szMsg, svDir, FALSE);

askfile:
    szMsg = "Enter a file specification to search for in " + svDir + ":";

    // Get a file specification from the user.
    if (AskText (szMsg , " *.*", svFileSpec) = BACK) then
        goto selectdir;
    endif;

    // Create a string list for the file listing.
    listFiles = ListCreate (STRINGLIST);

    if listFiles = LIST_NULL then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Set the file count to zero.
    nNumFiles = 0;

    // Show a message while the file list is being built.
    SdShowMsg ("Searching . . . ", TRUE);

    // Get the first file that matches the file spec.
    nResult = FindAllFiles (svDir, svFileSpec, svMatchingFileName, RESET);

    while(nResult = 0)
        // Add the file to the list.
        if ListAddString (listFiles, svMatchingFileName, AFTER) < 0 then

```

```

        MessageBox ("Unable to build complete file list", WARNING);
        goto showmatches;
    endif;

    // Increment the file counter.
    nNumFiles = nNumFiles + 1;

    // Find the next matching file name.
    nResult = FindAllFiles(svDir, svFileSpec, svMatchingFileName, CONTINUE);
endwhile;

showmatches:

    // Free all files and folders accessed by FindAllFiles. If your
    // setup does not target the Windows NT platform, this step is
    // not necessary.
    FindAllFiles(svDir, svFileSpec, svMatchingFileName, CANCEL);

    // Convert the file count to a string for display.
    NumToStr(svNumFiles, nNumFiles);

    // Clear the message that displayed while the file list was being built.
    SdShowMsg("", FALSE);

    // Display the files that match the file specification.
    szMsg = "Number of matching files : " + svNumFiles;
    if (SdShowInfoList(TITLE_TEXT, szMsg, listFiles) = BACK) then
        ListDestroy(listFiles);
        goto askfile;
    endif;

    // Remove the list from memory.
    ListDestroy(listFiles);

end;

```

## FindFile

The **FindFile** function searches a directory for a specified file. InstallShield returns the first matching file in the parameter svResult.

**Note** ■ This function searches only the specified subdirectory. It does not search an entire disk or directory tree.

### Syntax

```
FindFile ( szPath, szFileName, svResult );
```

## Parameters

**Table 125** ▪ FindFile Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPath</b>     | Specifies the name of the directory to search. Subdirectories beneath this directory are <i>not</i> searched.<br><br><br><b>Note</b> ▪ If the directory is enclosed in quotation marks, FindFile fails. To ensure that the folder name is not enclosed in quotation marks, call <i>LongPathToQuote</i> (szPath, FALSE) before calling FindFile. |
| <b>szFileName</b> | Specifies the name of the file to search for. Wild-card characters are allowed in this parameter.                                                                                                                                                                                                                                                                                                                                |
| <b>svResult</b>   | Returns the name of the first file that matches szFileName. This parameter contains the unqualified file name; that is, the drive designation and path are not included.                                                                                                                                                                                                                                                         |

## Return Values

**Table 126** ▪ FindFile Return Values

| Return Value  | Description                                                                     |
|---------------|---------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully found and returned the specified file. |
| <b>&lt; 0</b> | Indicates that the function was unable to find the file.                        |

## FindFile Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FindFile function.
*
* FindFile is called to search for the file Config.sys in the
* root of drive C.
*
\*-----*/

#define FILE_SPEC "Config.sys"
#define SEARCH_DIR "C:\\\"
```

```

#define TITLE_TEXT "FindFile Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_FindFile(HWND);

function ExFn_FindFile(hMSI)
    STRING svResult;
begin

    if (FindFile (SEARCH_DIR, FILE_SPEC, svResult) < 0) then
        MessageBox ("FindFile failed.", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE_TEXT, "Found: %s in %s.", svResult,
            SEARCH_DIR);
    endif;

end;

```

## FindWindow

The **FindWindow** function provides a way for advanced developers to get a handle to a window by specifying its window class and window name. If you know the class and window name of an application, you can get its handle. You can then use that handle to send messages directly to the window.

---

**Tip** ▪ To find the class and name of a window, run the Microsoft Spy.exe program.

### Syntax

```
FindWindow ( szClassName, szWinName );
```

## Parameters

**Table 127** ▪ FindWindow Parameters

| Parameter          | Description                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szClassName</b> | Specifies the name of the class to which the window belongs. To specify “any class,” pass a null string in this parameter.                          |
| <b>szWinName</b>   | Specifies the window caption (title). To return the handle of the topmost window in the specified class, pass a null string (“”) in this parameter. |

## Return Values

**Table 128** ▪ FindWindow Return Values

| Return Value    | Description                                                                    |
|-----------------|--------------------------------------------------------------------------------|
| <b>XXXX</b>     | The handle of the window.                                                      |
| <b>NULL (0)</b> | FindWindow was unable to find a window with the specified name and class name. |

## FindWindow Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the FindWindow and SendMessage functions.
*
* This script launches Windows Notepad and then calls
* FindWindow to locate the Notepad window. Next, it calls
* SendMessage to maximize the window; after a three-second
* delay, it calls SendMessage again to minimize the
* window. When the script ends, Windows NotePad remains
* open but minimized. Note that the parameters passed to
* SendMessage are Windows system messages whose values
* are defined as constants in this script.
*
* Note: Before running this script, set the preprocessor
*      constant NOTEPAD so that it references the fully-
*      qualified name of the Windows Notepad executable.
*
\*-----*/

#define NOTEPAD "C:\\Windows\\Notepad.exe"
```

```

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_FindWindow(HWND);

function ExFn_FindWindow(hMSI)
    NUMBER nMsg, nwParam, nlParam;
    HWND nHwnd;
begin

    // Do not display the setup's background window.
    Disable (BACKGROUND);

    // Open the Windows Notepad.
    if (LaunchApp (NOTEPAD, "") < 0 ) then
        MessageBox ("Unable to launch Notepad.", SEVERE);
        abort;
    endif;

    // Wait three seconds so we can view the window before
    // it's maximized.
    Delay (3);

    // Retrieve the handle of the Notepad window. The first
    // parameter is the window class. A null string in the
    // second parameter specifies the topmost Notepad window.
    nHwnd = FindWindow ("Notepad", "");

    if (nHwnd = NULL) then
        MessageBox ("Unable to find the Notepad window.", SEVERE);
    else
        // Send system command to maximize the window.
        SendMessage (nHwnd, WM_SYSCOMMAND, SC_MAXIMIZE, 0);

        // Wait three seconds so we can view the window
        // before it's minimized.
        Delay (3);

        // Send system command to minimize the window.
        SendMessage (nHwnd, WM_SYSCOMMAND, SC_MINIMIZE, nlParam);
    endif;

end;

```

## FormatMessage

The **FormatMessage** function provides the error message text associated with a large error code returned by a built-in InstallScript function.

### Syntax

```
FormatMessage ( nErrorReturnCode );
```

## Parameters

**Table 129** ▪ FormatMessage Parameters

| Parameter               | Description                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nErrorReturnCode</b> | Pass a large error code—for example, 2147024891 (0x80070005)—that was returned by a built-in InstallScript function. Passing the error code -1 will not produce useful results. |

## Return Value

A string containing the error message text associated with the error code nErrorReturnCode.

## FormatMessage Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
//-----
//
//  InstallShield Example Script
//
//  Demonstrates the FormatMessage function.
//
//  To demonstrate, deliberately call XCopyFile with a nonexistent source
//  directory, which should cause the function to fail. To provide system
//  details about the error, call FormatMessage and display the message
//  string in a MessageBox.
//
//-----

function OnBegin( )
    NUMBER nReturn;
begin

    // call XCopyFile on a nonexistent directory
    nReturn = XCopyFile("C:\\no_such_directory", "C:\\destination", COMP_NORMAL);

    // when XCopyFile fails, display the error message and exit the installer
    if (nReturn < 0) then
        MessageBox(FormatMessage(nReturn), SEVERE);
        abort;
    endif;

end;
```

# GetAndAddAllFilesCost

The **GetAndAddAllFilesCost** function determines the cost of all of the files that are in szSrcDir and that match the wild-card pattern that is identified by szWildcard; the function adds this cost to the current value of nvCostHigh and/or nvCostLow. This cost can then be passed to **FeatureAddCost**.

---

**Note** ▪ Note that **GetAndAddAllFilesCost** does not actually set any information to be used directly by the installation. You must call **FeatureAddCost** (as appropriate) after calling this function to add the additional cost to an existing feature.

## Syntax

```
GetAndAddAllFilesCost (szSrcDir, szWildcard, szTargetDir, nClusterSize, nvInstallCostHigh,  
    nvInstallCostLow, nvUninstallCost);
```

## Parameters

**Table 130** ▪ GetAndAddAllFilesCost Parameters

| Parameter                | Description                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSrcDir</b>          | The fully qualified path of the source location containing the files to determine the cost of.                                                                                                                   |
| <b>szWildcard</b>        | The wild card to match files against. Note that the function returns failure if no files that match szWildcard are found.                                                                                        |
| <b>szTargetDir</b>       | If nClusterSize is 0, the fully qualified path that the file is being installed to. This path is used to determine the cluster size of the target drive. If nClusterSize is non-zero, this parameter is ignored. |
| <b>nClusterSize</b>      | Specifies the cluster size of the target drive. If this parameter is 0, the function determines this information from szTargetDir.                                                                               |
| <b>nvInstallCostHigh</b> | The upper 31 bits of the install cost (in bytes) of this file is added to the current value of this variable.                                                                                                    |
| <b>nvInstallCostLow</b>  | The lower 31 bits of the install cost (in bytes) of this file is added to the current value of this variable.                                                                                                    |
| <b>nvUninstallCost</b>   | The uninstall cost of these files is added to the current value of this variable. This value equals 1 per file to be uninstalled. Therefore, 100 files to be uninstalled returns a value of 100.                 |

## Return Values

**Table 131** ▪ GetAndAddAllFilesCost Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# GetAndAddFileCost

The **GetAndAddFileCost** function determines the cost of the specified file and adds it to the current value of nvCostHigh and/or nvCostLow. This allows you to calculate and add up the cost of multiple files by calling the function multiple times in a loop. Set nvCostHigh and nvCostLow to zero before calling the function to determine the cost of a single file. This function is typically used when you need to determine the cost of an existing file on disk so this cost can then be passed to FeatureAddCost.

**Note** ▪ Note that this function does not actually set any information to be used directly by the installation. You must call *FeatureAddCost* (as appropriate) after calling this function to add the additional cost to an existing feature.

## Syntax

```
GetAndAddFileCost ( szSrcFile, szTargetDir, nClusterSize, nvCostHigh, nvCostLow );
```

## Parameters

**Table 132** ▪ GetAndAddFileCost Parameters

| Parameter           | Description                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSrcFile</b>    | The fully qualified path and file name of the existing file on disk to determine the cost of.                                                                                      |
| <b>szTargetDir</b>  | If nClusterSize is 0, the target folder for the file. This path is used to determine the cluster size of the target drive. If nClusterSize is non-zero, this parameter is ignored. |
| <b>nClusterSize</b> | Specifies the cluster size of the target drive. If this parameter is 0, the function determines this information from szTargetDir.                                                 |
| <b>nvCostHigh</b>   | The upper 31 bits of the installation cost (in bytes) of this file is added to the current value of this variable.                                                                 |
| <b>nvCostLow</b>    | The lower 31 bits of the installation cost (in bytes) of this file is added to the current value of this variable.                                                                 |

## Return Values

**Table 133** ▪ GetAndAddFileCost Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# GetArrayFromISArray

The **GetArrayFromISArray** function returns a pointer to an array of pointers that point to the actual data of the specified array. This function does not allocate any additional memory, but it returns a pointer to the data in the existing array. If vArray is a string array, the returned pointer can be passed to functions that take LPCWSTR\* or LPWSTR\* arguments; if vArray is a numeric array, the returned pointer can be passed to functions that take LPCDWORD\* or LPDWORD\* arguments.

## Syntax

```
GetCharArrayFromISArray (vArray);
```

## Parameters

**Table 134** ▪ GetCharArrayFromISArray Parameters

| Parameter     | Description                                      |
|---------------|--------------------------------------------------|
| <b>vArray</b> | Specifies the array to which you want a pointer. |

## Return Values

**Table 135** ▪ GetCharArrayFromISArray Return Values

| Return Value              | Description                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------|
| <b>pointer</b>            | A pointer to an array of pointers that point to the actual data of the specified array. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function failed.                                                     |

## Additional Information

Be careful when using the returned pointer to modify strings that are contained in the array. The length of the strings that are contained in string arrays are managed internally by the installation. Therefore, if you change the length of a string, the installation is no longer able to manage the data that are contained in the string array.

# GetCharArrayFromISStringArray

The **GetCharArrayFromISStringArray** function returns a pointer to an array of pointers to ANSI character strings that corresponds to the wide character strings that are contained in the specified array.

## Syntax

```
GetCharArrayFromISStringArray ( vArray );
```

## Parameters

**Table 136** ▪ GetCharArrayFromISStringArray Parameters

| Parameter     | Description                                             |
|---------------|---------------------------------------------------------|
| <b>vArray</b> | Specifies the string array to which you want a pointer. |

## Return Values

**Table 137** ▪ GetCharArrayFromISStringArray Return Values

| Return Value              | Description                                                  |
|---------------------------|--------------------------------------------------------------|
| <b>pointer</b>            | A pointer to an array of pointers to ANSI character strings. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function failed.                          |

## Additional Information

The **GetCharArrayFromISStringArray** function allocates additional memory for the array of pointers and the ANSI character strings. This pointer can be passed to functions that take LPCSTR\* or LPSTR\* arguments. After you are done with the newly created array, call **DeleteCharArray** to delete the array from memory.

If you call **CopyCharArrayToISStringArray** to write the data from the array of pointers back to the original string array, be careful when modifying strings that are contained in the array. Since the lengths of the strings that are contained in string arrays are managed internally by the installation, if you change the length of a string the entire string will not be copied back to the original array when you call **CopyCharArrayToISStringArray**.

# GetCurrentDialogName

**Project** ▪ This information applies to InstallScript projects.

The **GetCurrentDialogName** function retrieves the name of the currently displayed dialog as it was specified in the call to **EzDefineDialog** when the dialog was defined.

This information can be used to close the dialog by calling **EndDialog**.

## Syntax

```
GetCurrentDialogName ( svDialogName );
```

## Parameters

**Table 138** ▪ GetCurrentDialogName Parameters

| Parameter           | Description                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>svDialogName</b> | Returns the name of the currently displayed dialog, or a null string ("" ) if no dialog is currently displayed. |

## Return Values

**Table 139** ▪ GetCurrentDialogName Return Values

| Return Value               | Description                                                                                                                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | GetCurrentDialogName successfully retrieved the name of the currently displayed dialog.                                                                                                                       |
| <b>&lt; ISERR_SUCCESS</b>  | No dialog is currently displayed.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

# GetCurrentDir

The **GetCurrentDir** function returns the current directory.

**Note** ▪ When you are specifying a file in your script, always specify the full path (using the appropriate InstallShield system variable, for example, SRCDIR) rather than depend on the current folder having the appropriate value. The script internally executes code that can change the current folder, so its value may not be what you expect.

## Syntax

```
GetCurrentDir( svCurrentDir );
```

## Parameters

**Table 140** ▪ GetCurrentDir Parameters

| Parameter           | Description                    |
|---------------------|--------------------------------|
| <b>svCurrentDir</b> | Returns the current directory. |

## Return Values

**Table 141** ▪ GetCurrentDir Return Values

| Return Value               | Description                                                               |
|----------------------------|---------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully retrieved the current directory. |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to retrieve the current directory. |

# GetDir

The **GetDir** function removes the drive designation from the fully qualified path or file name passed in szPath and returns the remainder of the path or file name in svDir. The path must include a drive designation. It may be a UNC path.

In the following example, the fully qualified path C:\Windows is returned in svDir as \Windows.

```
GetDir("C:\Windows", svDir);
```

In the next example, the UNC path \\TheServer\TheSharedDevice\Programs is returned in svDir as \Programs.

```
GetDir("\\\\TheServer\\TheSharedDevice\\Programs", svDir);
```

## Syntax

```
GetDir ( szPath, svDir );
```

## Parameters

**Table 142** ▪ GetDir Parameters

| Parameter     | Description                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPath</b> | Specifies a path that includes a drive designation.                                                                                              |
| <b>svDir</b>  | Returns the path without the drive designation. If szPath is a UNC path, GetDir returns the path without the server name and shared device name. |

## Return Values

**Table 143** ▪ GetDir Return Values

| Return Value  | Description                                                                           |
|---------------|---------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully returned a path without a drive designation. |
| <b>&lt; 0</b> | Indicates that the function was unable to return a path without a drive designations. |

## GetDir Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetDir function.
 *
 * This script gets a fully qualified directory name from the
 * user. Next, it calls GetDir to return the selected directory
 * name without the drive designation. The resulting path is
 * then displayed.
 *
 \*-----*/

#define TITLE_TEXT "GetDir example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetDir(HWND);

function ExFn_GetDir(hMSI)
    STRING szMsg, svSelectedDir, svDirNameOnly;

```

```

begin

    // Get a fully qualified directory name from the user.
    AskPath ("Select a directory.", INSTALLDIR, svSelectedDir);

    // Get the directory name minus the drive designation.
    if (GetDir (svSelectedDir, svDirNameOnly) < 0) then
        // Report the error.
        MessageBox ("GetDir failed.", SEVERE);
    else
        // Display the directory name as it was returned by GetDir.
        sprintfBox (INFORMATION, TITLE_TEXT,
            "Selected directory without drive designation: %s",
            svDirNameOnly);
    endif;

end;

```

## GetDisk

The **GetDisk** function extracts the disk drive designation from the fully qualified path or file name specified by `szPath` and returns it in `svDisk`.

### Syntax

```
GetDisk ( szPath, svDisk );
```

## Parameters

**Table 144** ▪ GetDisk Parameters

| Parameter     | Description                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPath</b> | Specifies a fully qualified path or file name that includes a drive designation. If a drive designation is not included, GetDisk will fail. The value passed in szPath may be a UNC path. |
| <b>svDisk</b> | Returns the drive designation (which includes the colon). If szPath is a UNC path, GetDisk returns the server name and shared device name in the format \\server\sharedevice.             |

## Return Values

**Table 145** ▪ GetDisk Return Values

| Return Value  | Description                                                              |
|---------------|--------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully returned the drive designation. |
| <b>&lt; 0</b> | Indicates that the function was unable to return the drive designation.  |

## GetDisk Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetDisk function.
 *
 * This script gets a fully qualified directory name from
 * the user. Next, it calls GetDisk to return the disk drive
 * designation. The drive designation is then displayed.
 *
 \*-----*/

#define TITLE_TEXT "GetDisk example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetDisk(HWND);

function ExFn_GetDisk(hMSI)
    STRING svSelectedDir, svDisk;

```

```

begin

    // Get a fully qualified directory name from the user.
    AskPath ("Select a directory.", INSTALLDIR, svSelectedDir);

    // Get the drive designation from the selected directory name.
    if (GetDisk (svSelectedDir, svDisk) < 0) then
        // Report the error.
        MessageBox ("GetDir failed.", SEVERE);
    else
        // Display the drive designation as it was returned by GetDisk.
        sprintfBox (INFORMATION, TITLE_TEXT, "Disk drive: %s", svDisk);
    endif;

end;

```

## GetDiskInfo

The **GetDiskInfo** function gets information about a specified disk drive. By inspecting the values assigned to members of this variable, your script can determine the information about a disk drive.

### Syntax

```
GetDiskInfo ( _DISK_INFO& pdi );
```

### Parameters

**Table 146** ▪ GetDiskInfo Parameters

| Parameter                  | Description                                                                                                                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>_DISK_INFO&amp; pdi</b> | Specifies a pointer to an existing _DISK_INFO structure (allocated by the installation before calling the function) that specifies the information to retrieve and contains the specified information after the function returns. |

The following table shows the meaning of each \_DISK\_INFO member:

**Table 147** ▪ \_DISK\_INFO Members

| Member                       | Meaning                                                                        |
|------------------------------|--------------------------------------------------------------------------------|
| <b>szDiskPath[_MAX_PATH]</b> | Specifies the fully qualified path of the drive to return the information for. |

**Table 147** ▪ `_DISK_INFO` Members (cont.)

| Member                  | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nInfoToQuery</b>     | Specifies the information to query. Possible values are the following: <ul style="list-style-type: none"> <li>● <b>DISK_INFO_QUERY_ALL</b>—Queries all information about the disk drive.</li> <li>● <b>DISK_INFO_QUERY_BYTES_PER_CLUSTER</b>—Queries the bytes per cluster (cluster-size) of the drive.</li> <li>● <b>DISK_INFO_QUERY_DISK_TOTAL_SPACE</b>—Queries the total space on the drive.</li> <li>● <b>DISK_INFO_QUERY_DISK_FREE_SPACE</b>—Queries the free space on the drive.</li> <li>● <b>DISK_INFO_QUERY_DRIVE_TYPE</b>—Queries the drive type.</li> </ul>                                                                                                                                                |
| <b>nBytesPerCluster</b> | Returns the number of bytes per cluster if <code>DISK_INFO_QUERY_BYTES_PER_CLUSTER</code> was specified in <code>nInfoToQuery</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>nTotalSpaceHigh</b>  | Returns the upper 31 bits of the total space on the target drive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>nTotalSpaceLow</b>   | Returns the lower 31 bits of the total space on the target drive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>nFreeSpaceHigh</b>   | Returns the upper 31 bits of the free space on the target drive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>nFreeSpaceLow</b>    | Returns the lower 31 bits of the free space on the target drive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>nDriveType</b>       | Returns the drive type using the same constants returned by the Windows API <code>GetDriveType</code> . For convenience, the following constants are predefined: <ul style="list-style-type: none"> <li>● <b>DRIVE_UNKNOWN</b>—The drive type is unknown.</li> <li>● <b>DRIVE_NO_ROOT_DIR</b>—The drive type is defined as no root directory.</li> <li>● <b>DRIVE_REMOVABLE</b>—The drive type is defined as removable.</li> <li>● <b>DRIVE_FIXED</b>—The drive type is defined as fixed.</li> <li>● <b>DRIVE_REMOTE</b>—The drive type is defined as remote.</li> <li>● <b>DRIVE_CDROM</b>—The drive type is defined as a CD-ROM.</li> <li>● <b>DRIVE_RAMDISK</b>—The drive type is defined as a RAM DISK.</li> </ul> |
| <b>nResultDiskSpace</b> | This member contains valid information on return when any of the following flags are specified: <ul style="list-style-type: none"> <li>● <code>DISK_INFO_QUERY_BYTES_PER_CLUSTER</code></li> <li>● <code>DISK_INFO_QUERY_DISK_TOTAL_SPACE</code></li> <li>● <code>DISK_INFO_QUERY_DISK_FREE_SPACE</code></li> </ul> This member returns the result of querying the information.                                                                                                                                                                                                                                                                                                                                        |

## Return Values

**Table 148** ▪ GetDiskInfo Return Values

| Return Value              | Description                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.                                                                        |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was unsuccessful. If a null pointer is passed to the function, this value is returned. |

You can check the `nResultDiskSpace` member to determine whether the query was successful.

## GetDiskInfo Example

**Note** ▪ To call this function in a Basic MSI installation, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetDiskInfo function.
 *
 * This script gets the amount of free disk space on a Windows drive
 * and displays that amount in a message box.
 *
 \*-----*/

function OnBegin( )
    _DISK_INFO di;
    NUMBER n; // to do: something with function return values
    NUMBER nvSizeTargetHigh, nvSizeTargetLow, nUnitsTarget;
begin

    // init. _DISK_INFO members: what drive, what info
    di.szDiskPath = WINDISK;
    di.nInfoToQuery = DISK_INFO_QUERY_DISK_FREE_SPACE;

    n = GetDiskInfo(&di);

    // change to desired unit for free space
    nUnitsTarget = MBYTES;

    n = ConvertSizeToUnits(
        di.nFreeSpaceHigh, di.nFreeSpaceLow, BYTES,
        nvSizeTargetHigh, nvSizeTargetLow, nUnitsTarget);

    sprintfBox(INFORMATION, "Free Space",
        "Free space: %d MB",

```

```

        nvSizeTargetLow);

end;

```

## GetDiskSpace

This function is obsolete. Use the [GetDiskInfo](#) function instead.

The **GetDiskSpace** function returns the amount of free space—in bytes—on the drive or path specified in szPath.

### Syntax

```
GetDiskSpace ( szDrive );
```

### Parameters

**Table 149** ▪ GetDiskSpace Parameters

| Parameter     | Description                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>szPath</b> | Specifies the path for which the function returns the amount of space available. The value specified can be a UNC path. |

### Return Values

**Table 150** ▪ GetDiskSpace Return Values

| Return Value  | Description                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt; 0</b> | The number of bytes free in the specified directory. The maximum value returned is 2 GB. Free disk space greater than that returns as 2 GB. Call GetDiskSpaceEx when your setup needs to check for free space greater than 2 GB. |
| <b>&lt; 0</b> | Indicates that GetDiskSpace was unable to obtain the amount of free space.                                                                                                                                                       |

## GetDiskSpace Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetDiskSpace function.
 *
 * This script gets a fully qualified path from the end user.

```

```

* It then extracts the drive designation from the path, gets
* the amount of free space on that drive, and displays the
* amount of free space in a message box.
*
* A script-defined function is used to insert commas if
* necessary into the number before it's displayed.
*
\*-----*/

    // User-defined function to format a number in a string.
    prototype FormatIntString (BYREF STRING);

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_GetDiskSpace(HWND);

function ExFn_GetDiskSpace(hMSI)
    STRING svResultPath, svDrive;
    LONG   lFreeSpace;
    STRING svFreeSpace;
begin

    // Prompt for a target path; use C as the default.
    AskPath ("Select drive:", "C:\\", svResultPath);

    // Get the drive designation from the path.
    GetDisk (svResultPath, svDrive);

    // Get the amount of free disk space on that drive.
    lFreeSpace = GetDiskSpace (svDrive);

    if (lFreeSpace < 0) then
        // Handle an error from GetDiskSpace.
        MessageBox ("GetDiskSpace failed.", SEVERE);
    else
        // Convert the free disk space value to a string.
        NumToStr (svFreeSpace, lFreeSpace);

        // Insert commas into the number if necessary.
        FormatIntString (svFreeSpace) ;

        // Report the amount of free space.
        MessageBox (svFreeSpace + " bytes free on drive " + svDrive + ".",
                    INFORMATION);
    endif;

end;

function FormatIntString(svInteger)
// Insert commas if necessary into an integer
// that's been stored in a string variable.
    INT nLen;
    STRING svSubStr, svTemp;

```

```

begin
  nLen = StrLength (svInteger);

  if nLen > 3 then
    nLen = nLen - 3;
    StrSub (svTemp , svInteger, nLen, 3);

    while nLen > 3
      nLen = nLen - 3;
      StrSub (svSubStr, svInteger, nLen, 3);
      svTemp = svSubStr + "," + svTemp;
    endwhile;

    StrSub (svSubStr, svInteger, 0,nLen);
    svInteger = svSubStr + "," + svTemp;
  endif;
end;

```

## GetDiskSpaceEx

This function is obsolete. Use the [GetDiskInfo](#) function instead.

The **GetDiskSpaceEx** function returns the amount of free space on the specified path. The value passed in nUnits determines whether the value returned by GetDiskSpaceEx is a measure of bytes, kilobytes, megabytes, or gigabytes.

### Syntax

```
GetDiskSpaceEx ( szDrive, nUnits );
```

## Parameters

**Table 151** ▪ GetDiskSpaceEx Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPath</b> | Specifies the path for which the function returns the amount of space available. The value specified can be a UNC path.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>nUnits</b> | <p>Pass one of the following predefined constants to indicate the measurement unit:</p> <ul style="list-style-type: none"> <li>● <b>BYTES</b>—Indicates that GetDiskSpaceEx should return the number of free bytes.</li> <li>● <b>KBYTES</b>—Indicates that GetDiskSpaceEx should return the number of free kilobytes.</li> <li>● <b>MBYTES</b>—Indicates that GetDiskSpaceEx should return the number of free megabytes.</li> <li>● <b>GBYTES</b>—Indicates that GetDiskSpaceEx should return the number of free gigabytes.</li> </ul> |

## Return Values

**Table 152** ▪ GetDiskSpaceEx Return Values

| Return Value  | Description                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>&gt; 0</b> | The number of free bytes, kilobytes, megabytes, or gigabytes in the specified directory, depending on the value of nUnits. |
| <b>&lt; 0</b> | Indicates that GetDiskSpaceEx was unable to obtain the amount of free space.                                               |

## Additional Information

The limit of GetDiskSpaceEx is 2 giga-units ( $2^{31}$ ) of the measurement unit you pass in nUnits. When you specify BYTES, the limit is 2 GB; when you specify KBYTES, the limit is 2 TB; and so on. You should specify KBYTES for most setups.

GetDiskSpaceEx returns the available space rounded down to the nearest single unit specified in nUnits. For example, if you specify GBYTES, a path that has 2.5 GB available will return 2. For setups that require more precise space information, call the Windows API function GetDiskFreeSpaceEx directly.

## GetDiskSpaceEx Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetDiskSpaceEx function.
 *
 * This script gets a fully qualified path from the end user.
 * It then extracts the drive designation from the path, gets
 * the amount of free space on that drive, and displays the
 * amount of free space in a message box.
 *
\*-----*/

STRING    szPath;

          INT        iResult;

#include "ifx.h"

program

    // Prompt for a target path.

    szPath = PROGRAMFILES;
    iResult = SdAskDestPath
    ("Select Folder\nSelect the folder to check for available disk space.", " ", szPath, 0);

    if (iResult < 0) then
        MessageBox("Unable to display dialog.", SEVERE);
    endif;

    // Get the amount of free disk space (in kilobytes) for the specified path.

    iResult = GetDiskSpaceEx(szPath, KBYTES);

    if (iResult < 0) then
        MessageBox("Unable to get available disk space.", SEVERE);
    endif;

    // Display the amount of space available.

    SprintfBox(INFORMATION, "Space Available", "%d KB available on %s.", iResult, szPath);

endprogram

```

## GetEnvVar

The **GetEnvVar** function retrieves the current value of an environment variable.

### Syntax

```
GetEnvVar ( szParameter, svValue );
```

## Parameters

**Table 153** ▪ GetEnvVar Parameters

| Parameter          | Description                                                                    |
|--------------------|--------------------------------------------------------------------------------|
| <b>szParameter</b> | Specifies the name of the environment variable whose value is to be retrieved. |
| <b>svValue</b>     | Returns the current value of the environment variable.                         |

## Return Values

**Table 154** ▪ GetEnvVar Return Values

| Return Value  | Description                                                                               |
|---------------|-------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function retrieved the value of the environment variable.              |
| <b>&lt; 0</b> | Indicates that the function was unable to retrieve the value of the environment variable. |

## GetEnvVar Example

This script is structured for use in a Basic MSI installation. To call this function in a Basic MSI installation, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release. To run this code in an InstallScript or InstallScript MSI installation, copy only the code that is in between the begin and end statements and paste it into your script's OnBegin event handler function.

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetEnvVar function.
 *
 * GetEnvVar is called to get the value of the environment
 * variable named TEMP.
 *
 \*-----*/

#define TITLE_TEXT "GetEnvVar Example"

#define ENV_TEMP "TEMP"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"
```

```

export prototype ExFn_GetEnvVar(HWND);

function ExFn_GetEnvVar(hMSI)
    STRING svEnvVar;
begin
    // Get the value of the environment variable specified by ENV_TEMP.
    if (GetEnvVar (ENV_TEMP, svEnvVar) < 0) then
        // Report the error.
        MessageBox ("Environment variable " + ENV_TEMP + " not found.", SEVERE);
    else
        // Display the value of the environment variable.
        sprintfBox (INFORMATION, TITLE_TEXT, "%s = %s", ENV_TEMP, svEnvVar);
    endif;
end;

```

## GetExtendedErrInfo

---

**Project** ▪ This information applies to InstallScript projects.

The **GetExtendedErrInfo** function returns the error information that was set by SetExtendedErrInfo. Many InstallScript functions call SetExtendedErrInfo(\_\_FILE\_\_, \_\_LINE\_\_, nError) internally.

### Syntax

```
GetExtendedErrInfo ( svScriptFile, nvLineNumber, nvError );
```

## Parameters

**Table 155** ▪ GetExtendedErrInfo Parameters

| Parameter           | Description                                          |
|---------------------|------------------------------------------------------|
| <b>svScriptFile</b> | Returns the script file in which the error occurred. |
| <b>nvLineNumber</b> | Returns the line number in which the error occurred. |
| <b>nvError</b>      | Returns the error code for the error.                |

## Return Values

**Table 156** ▪ GetExtendedErrInfo Return Values

| Return Value               | Description                                                |
|----------------------------|------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully retrieved the error information. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to retrieve the error information.     |

# GetExtents

The **GetExtents** function retrieves the dimensions of a screen—in pixels. The width of the screen is returned in nvDx and the height is returned in nvDy. For example, a standard VGA monitor returns 640 in nvDx and 480 in nvDy.

**Note** ▪ The screen dimensions of the target machine can be gotten through the Windows Installer service by using the ScreenX and ScreenY properties.

## Syntax

```
GetExtents ( nvDx, nvDy );
```

## Parameters

**Table 157** ▪ GetExtents Parameters

| Parameter   | Description                                 |
|-------------|---------------------------------------------|
| <b>nvDx</b> | Returns the width of the screen in pixels.  |
| <b>nvDy</b> | Returns the height of the screen in pixels. |

## Return Values

**Table 158** ▪ GetExtents Return Values

| Return Value  | Description                                                                    |
|---------------|--------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully retrieved the dimensions of a screen. |
| <b>&lt; 0</b> | Indicates that the function was unable to retrieve the values.                 |

## GetExtents Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetExtents function.
 *
 * This script calls GetExtents to obtain the current video
 * resolution of the target system. It then displays that
 * information in a dialog.
 *
 \*-----*/

#define TITLE_TEXT "GetExtents example"
#define MSG_TEXT  "Video Resolution: %d by %d"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetExtents(HWND);

function ExFn_GetExtents(hMSI)
    NUMBER nvDx, nvDy;
begin
```

```

    // Get the video resolution of the target system.
    if (GetExtents (nvDx, nvDy) < 0) then
        // Report the error.
        MessageBox ("GetExtents failed.", SEVERE);
    else
        // Display the information
        sprintfBox (INFORMATION, TITLE_TEXT, MSG_TEXT, nvDx, nvDy);
    endif;

end;

```

## GetFileInfo

Call the **GetFileInfo** function to determine a file's or directory's attributes, modify date, time, MD5 signature, or size. In each GetFileInfo statement, you can request only one of the data. For example, to obtain the date and time information for a file or directory, you must call GetFileInfo twice—once to obtain the date and once to obtain the time.

### Syntax

```
GetFileInfo ( szPathName, nType, nvResult, svResult );
```

## Parameters

**Table 159** • GetFileInfo Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPathName</b> | Specifies the fully qualified name of the file or directory about which you want to retrieve information. You can specify a valid Uniform Resource Locator (URL) in this parameter unless you pass FILE_ATTRIBUTE or FILE_SHARED_COUNT as the nType parameter, in which case the function fails and returns ISERR_INVALID_ARG. To check the validity of a URL, call Is(VAILD_PATH, szURL).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>nType</b>      | <p>Specifies the type of file or directory information to retrieve. If the information is a number, GetFileInfo places it in nvResult. If the information is a string, GetFileInfo places it in svResult. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>FILE_ATTRIBUTE</b>—The attribute of the file or directory is returned in nvResult.</li> <li>• <b>FILE_DATE</b>—The modify date of the file or directory in the format YYYY\MM\DD is returned in svResult.</li> <li>• <b>FILE_MD5_SIGNATURE</b>—Returns the MD5 signature of the file specified in svResult. Generating and returning an MD5 signature is an expensive operation that requires reading the contents of the entire file. Only use this parameter when absolutely necessary. FILE_MD5_SIGNATURE is not supported for URLs.</li> </ul> <div>  <p><b>Note</b> • Raw MD5 signature data for a particular file consists of 16 generated numeric values of 16 bit each (between 0x00 abd 0xFF). These values are usually stored in a string of unsigned characters. However, the InstallScript language does not support unsigned characters, so instead of returning the raw MD5 file data, each of the 16 numeric values are converted to their string equivalent and placed in the resulting string. This results in a string of 32 characters, where each set of two characters represent a single numeric value. This is sometimes referred to as a MD5 hex string.</p> </div> <ul style="list-style-type: none"> <li>• <b>FILE_SHARED_COUNT</b>—The file's reference count.</li> <li>• <b>FILE_SIZE</b>—The size in bytes is returned in nvResult (same as FILE_SIZE_LOW).</li> <li>• <b>FILE_SIZE_LOW</b>—The lower 31 bits of the file's size (in bytes) is returned in nvResult. If the size of the file is more than 2GB, the size of the file is equal to the value returned for FILE_SIZE_HIGH multiplied by 2GB added to the value returned for FILE_SIZE_LOW.</li> <li>• <b>FILE_SIZE_HIGH</b>—The upper 31 bits of the file's size (in bytes) is returned in nvResult. This value is 0 (zero) if the file is less than 2GB. If not, the size of the file is equal to the value returned for FILE_SIZE_HIGH multiplied by 2GB added to the value returned for FILE_SIZE_LOW.</li> <li>• <b>FILE_TIME</b>—The modify time of the file or directory in the format HH:MM:SS is returned in svResult.</li> </ul> |

Table 159 ■ GetFileInfo Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <div><div><div></div></div><div><p><b>Note</b> - After calling <code>GetFileInfo</code> with <code>FILE_ATTRIBUTE</code> as the second parameter (<code>nType</code>), use if-then-else logic to determine the file's or directory's attributes. If <code>nvResult = FILE_ATTR_NORMAL</code>, then no attributes are set. If <code>nvResult != FILE_ATTR_NORMAL</code>, test the result of bitwise AND (&amp;) operations on <code>nvResult</code> and one or more of the following file attribute constants to determine which attributes are set:</p><ul style="list-style-type: none"><li>● <code>FILE_ATTR_NORMAL</code>: The file is a normal file.</li><li>● <code>FILE_ATTR_ARCHIVED</code>: The file is archived.</li><li>● <code>FILE_ATTR_DIRECTORY</code>: The file is a directory.</li><li>● <code>FILE_ATTR_HIDDEN</code>: The file is hidden.</li><li>● <code>FILE_ATTR_READONLY</code>: The file is read-only.</li><li>● <code>FILE_ATTR_SYSTEM</code>: The file is a system file.</li></ul><pre>if (nvResult = FILE_ATTR_NORMAL) then     //The file is NORMAL. else     if (FILE_ATTR_HIDDEN &amp; nvResult) then         //The file is HIDDEN.     endif;      if (FILE_ATTR_READONLY &amp; nvResult) then         //The file is READ-ONLY.     endif; endif;</pre></div></div> |
| <b>nvResult</b> | Returns numeric information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>svResult</b> | Returns string information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Return Values

**Table 160** • GetFileInfo Return Values

| Return Value                     | Description                                                                        |
|----------------------------------|------------------------------------------------------------------------------------|
| <b>0</b>                         | Indicates that the function successfully retrieved the requested file information. |
| <b>ISERR_INVALID_ARG (-2)</b>    | Indicates that an invalid argument was passed to the function.                     |
| <b>All other negative values</b> | Indicates that the function was unable to retrieve the requested information.      |

## GetFileInfo Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetFileInfo function.
 *
 * GetFileInfo is called to retrieve the time, date, and
 * attributes of a file.
 *
 * Note: In order for this script to run correctly, you
 *       must set the constant EXAMPLE_TXT to the name
 *       of an existing file on the target system.
 *
 \*-----*/

#define EXAMPLE_FILE "C:\\IO.sys"
#define TITLE_TEXT  "GetFileInfo Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetFileInfo(HWND);

function ExFn_GetFileInfo(hMSI)
    STRING svResult, szAttributes;
    NUMBER nvResult;
    LIST  listID;
begin

    // Create a list to store information about the file.
    listID = ListCreate (STRINGLIST);

    // Get the date the file was created or last updated into svResult.

```

```

if (GetFileInfo (EXAMPLE_FILE, FILE_DATE, nvResult, svResult) = 0) then
    // Add the file date to the list.
    ListAddString (listID, "File date: " + svResult, AFTER);
endif;

// Get the time the file was created or last updated into svResult.
if (GetFileInfo (EXAMPLE_FILE, FILE_TIME, nvResult, svResult) = 0) then
    // Add the file time to the list.
    ListAddString (listID, "File time: " + svResult, AFTER);
endif;

// Get the file attributes into nvResult.
if (GetFileInfo (EXAMPLE_FILE, FILE_ATTRIBUTE, nvResult, svResult) = 0) then
    // Test for no attribute.
    if (nvResult = FILE_ATTR_NORMAL) then
        // No attributes are set. Add that info to the list
        ListAddString(listID, "File attributes: Normal", AFTER);
    else
        // Append attributes to this string.
        szAttributes = "File attributes: ";

        // Is it archived?
        if (FILE_ATTR_ARCHIVED & nvResult) then
            szAttributes = szAttributes + "archived ";
        endif;

        // Is it hidden?
        if (FILE_ATTR_HIDDEN & nvResult) then
            szAttributes = szAttributes + "hidden ";
        endif;

        // Is it read-only?
        if (FILE_ATTR_READONLY & nvResult) then
            szAttributes = szAttributes + "read-only ";
        endif;

        // Is it a system file?
        if (FILE_ATTR_SYSTEM & nvResult) then
            szAttributes = szAttributes + "system ";
        endif;

        // Is it a directory?
        if (FILE_ATTR_DIRECTORY & nvResult) then
            szAttributes = szAttributes + "directory ";
        endif;

    endif;

    // Add the file attributes to the list.
    ListAddString (listID, szAttributes, AFTER);

endif;

// Display the list.
SdShowInfoList (TITLE_TEXT, EXAMPLE_FILE, listID);

```

```
// Remove the list from memory.  
ListDestroy (listID);  
  
end;
```

## GetFolderNameList

The **GetFolderNameList** function is used to enumerate all program item shortcuts and subfolders in a specified folder. This function can also be used to enumerate program item shortcuts and subfolders in the root folder.

### Syntax

```
GetFolderNameList ( szFolderName, listItemsID, listSubFoldersID );
```

## Parameters

**Table 161** ▪ GetFolderNameList Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFolderName</b>     | <p>Specifies the name of the folder to be queried. You can specify a fully qualified path for szFolderName, such as:</p> <pre>"C:\\Windows\\Start Menu\\Programs\\Accessories\\Games"</pre> <p>If szFolderName is null, <b>GetFolderNameList</b> searches the default Programs directory. If you do not specify an absolute path (a path that includes a drive specification, for example, "C:\\Program Files\\AppName") for szFolderName, <b>GetFolderNameList</b> searches for a subfolder under the default Programs directory; the location depends on the value of the InstallScript variable ALLUSERS, as well as the version of Windows on the target system.</p> <p>You can also use an InstallScript system variable:</p> <ul style="list-style-type: none"> <li>● <b>FOLDER_DESKTOP</b>—Searches the Desktop folder.</li> <li>● <b>FOLDER_STARTUP</b>—Searches the Startup menu.</li> <li>● <b>FOLDER_STARTMENU</b>—Searches the Start menu.</li> <li>● <b>FOLDER_PROGRAMS</b>—Searches the Start Menu\\Programs folder.</li> </ul> <p>Or you could use a relative path, such as:</p> <pre>FOLDER_PROGRAMS ^ "ACCESSORIES\\GAMES"</pre> |
| <b>listItemsID</b>      | <p>Returns a list with the names of the program item shortcuts in szFolderName. Note that if szFolderName includes both personal and common program items, the list returned in this parameter will contain either the common or personal program item shortcuts, but not both. The list identified by listItemsID must already have been initialized by a call to <b>ListCreate</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>listSubFoldersID</b> | <p>Returns a list with the names of the subfolders in szFolderName. Note that if szFolderName includes both personal and common folders, the list returned in this parameter will contain either the common or personal folders, but not both. The list identified by listSubFoldersID must already have been initialized by a call to <b>ListCreate</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Return Values

**Table 162** ▪ GetFolderNameList Return Values

| Return Value | Description                                                                                 |
|--------------|---------------------------------------------------------------------------------------------|
| <b>0</b>     | <b>GetFolderNameList</b> successfully retrieved all the programs items and subfolder names. |

**Table 162** ▪ GetFolderNameList Return Values (cont.)

| Return Value | Description                                                                                                                                                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| < 0          | <p><b>GetFolderNameList</b> was unable to retrieve the program items and subfolder names.</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

## GetFolderNameList Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the GetFolderNameList function.
*
* GetFolderNameList is called to retrieve all of the folders
* and program items on the desktop.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetFolderNameList(HWND);

function ExFn_GetFolderNameList(hMSI)
    NUMBER nResult;
    LIST listItemsID, listFoldersID;
begin

    // Create lists for folders and program names.
    listItemsID = ListCreate (STRINGLIST);
    listFoldersID = ListCreate (STRINGLIST);

    if (listItemsID = LIST_NULL) || (listFoldersID = LIST_NULL) then
        MessageBox ("Unable to create lists.", SEVERE);
    else
        // Display a message box while building the list.
        SdShowMsg ("Searching . . . please wait.", TRUE);

        // Place the folder and program names into the lists.
        nResult = GetFolderNameList (FOLDER_DESKTOP, listItemsID, listFoldersID);

        // Close the message box.
        SdShowMsg ("", FALSE);

```

```

if (nResult < 0) then
    MessageBox ("Unable to retrieve desktop folder and program names.",
                SEVERE);
else

    // Display the lists.
    repeat

        // Disable the Back button.
        Disable (BACKBUTTON);

        // Display the list of items.
        nResult = SdShowInfoList ("", "Items list:", listItemsID);

        // Enable the Back button.
        Enable (BACKBUTTON);

        // Display the list of folders.
        nResult = SdShowInfoList ("", "Folders list:", listFoldersID);

    until (nResult = NEXT);

endif;
endif;

end;

```

## GetFont

The **GetFont** function builds a font and retrieves its handle. You can use the font handle to specify the font used by the controls in a custom dialog.

---

**Note** ▪ *InstallShield deletes all fonts created with this function when the installation terminates. In addition, InstallShield releases all system resources upon termination.*

### Syntax

```
GetFont ( szFontName, nPointSize, nAttributes );
```

## Parameters

**Table 163** ▪ GetFont Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFontName</b>  | Specifies the name of the font that you want to build.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>nPointSize</b>  | Specifies the point size of the font that you want to build.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>nAttributes</b> | <p>Specifies the style of the font. Pass one or more of the following predefined constants in this parameter. Specify multiple styles by combining constants with the bitwise OR operator (   ).</p> <ul style="list-style-type: none"> <li>● <b>STYLE_BOLD</b>—Specifies a bold style font.</li> <li>● <b>STYLE_ITALIC</b>—Specifies that you want the font to be italicized.</li> <li>● <b>STYLE_NORMAL</b>—Specifies a normal style font.</li> <li>● <b>STYLE_UNDERLINE</b>—Specifies that you want the characters to be underlined.</li> </ul> |

## Return Values

**Table 164** ▪ GetFont Return Values

| Return Value | Description             |
|--------------|-------------------------|
| <b>XXXX</b>  | The handle to the font. |

If GetFont cannot find the font that is named in szFontName, the function builds the Arial font and returns a handle to that font.

## GetFont Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the GetFont and CtrlSetFont functions.
*
* This example script calls GetFont to retrieve the handles
* of four fonts. These handles are then passed to CtrlSetFont
* to set the font of the static text fields in a custom dialog
* box.
*
* The "custom" dialog used in this script is actually the

```

```

* InstallShield dialog that is displayed by the built-in
* function SetupType. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
\*-----*/

// Dialog and control IDs.
#define RES_DIALOG_ID      10203 // ID of the custom dialog
#define RES_PBUT_NEXT      1 // ID of Next button
#define RES_PBUT_CANCEL    9 // ID of Cancel button
#define RES_TEXT_1         202 // ID of first static text box

#define RES_TEXT_2         210 // ID of second static text box
#define RES_TEXT_3         220 // ID of third static text box
#define RES_TEXT_4         230 // ID of fourth static text box

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetFont(HWND);

function ExFn_GetFont(hMSI)
    STRING szDialogName;
    NUMBER nResult, nCmdValue;
    HWND hFont1, hFont2, hFont3, hFont4, hwndDlg;
    BOOL bDone;
begin

    // Get the handle of the fonts to use for the static text
    // that is displayed by the custom dialog.
    hFont1 = GetFont("Arial", 14, STYLE_BOLD);
    hFont2 = GetFont("Times New Roman", 11, STYLE_ITALIC);
    hFont3 = GetFont("Arial", 10, STYLE_BOLD);
    hFont4 = GetFont("Courier New", 9, STYLE_NORMAL);

    if (hFont1 = 0 || hFont2 = 0 || hFont3 = 0 || hFont4 = 0) then
        // Report an error; then terminate.
        MessageBox ("Unable to get all fonts. ", SEVERE);
        abort;
    endif;

    // Specify a name to identify the custom dialog in this installation.
    szDialogName = "CustomDialog";

    // Define the dialog. Pass a null string in the second parameter
    // to get the dialog from _isuser.dll or _isres.dll. Pass a null
    // string in the third parameter because the dialog is identified
    // by its ID in the fourth parameter.

    nResult = EzDefineDialog (szDialogName, "", "", RES_DIALOG_ID);

    if (nResult < 0) then
        // Report an error; then terminate.
        MessageBox ("Error in defining dialog.", SEVERE);

```

```

        abort;
    endif;

    // Initialize indicator used to control the while loop.
    bDone = FALSE;

    // Loop until done.
    repeat

        // Display the dialog and return the next dialog event.
        nCmdValue = WaitOnDialog (szDialogName);

        // Respond to the event.
        switch (nCmdValue)
        case DLG_CLOSE:
            // The user clicked the window's Close button.
            Do (EXIT);
        case DLG_ERR:
            MessageBox ("Unable to display dialog. Setup canceled.", SEVERE);
            abort;
        case DLG_INIT:
            // Initialize the back, next, and cancel button enable/disable states
            // for this dialog and replace %P, %VS, %VI with
            // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
            // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
            hwndDlg = CmdGetHwndDlg(szDialogName);
            SdGeneralInit(szDialogName, hwndDlg, 0, "");

            // Set the font and text for static text box 1.
            if (CtrlSetFont (szDialogName, hFont1, RES_TEXT_1) = 0) then
                CtrlSetText (szDialogName, RES_TEXT_1,
                    "This text is set in 14-point Arial bold.");
            else
                CtrlSetText (szDialogName, RES_TEXT_1,
                    "Unable to set font for first static text box.");
            endif;

                CtrlSetText (szDialogName, RES_TEXT_2,
                    "This text is set in 11-point Times New Roman italic.");
            else
                CtrlSetText (szDialogName, RES_TEXT_2,
                    "Unable to set font for second static text box.");
            endif;

            // Set font and text for static text box 3.
            if (CtrlSetFont (szDialogName, hFont3, RES_TEXT_3) = 0) then
                CtrlSetText (szDialogName, RES_TEXT_3,
                    "This text is set in 10-point Arial bold.");
            else
                CtrlSetText (szDialogName, RES_TEXT_3,
                    "Unable to set font for third static text box.");
            endif;

            // Set font and text for static text box 4.

```

```

        if (CtrlSetFont (szDialogName, hFont4, RES_TEXT_4) = 0) then
            CtrlSetText (szDialogName, RES_TEXT_4,
                "This text is set in 9-point Courier New.");
        else
            CtrlSetText (szDialogName, RES_TEXT_4,
                "Unable to set font for fourth static text box.");
        endif;
    case RES_PBUT_NEXT:
        bDone = TRUE;
    case RES_PBUT_CANCEL:
        // The user clicked the Cancel button.
        Do (EXIT);
    endswitch;

until bDone;

// Close the dialog.
EndDialog (szDialogName);

// Free the dialog from memory.
ReleaseDialog (szDialogName);

end;

```

## GetLine

The **GetLine** function reads a line of text from a text file opened in read-only mode. Before you call GetLine, you must first call `OpenFileMode` to set the file mode to read-only and then call `OpenFile` to open the file (which can be a file on the Internet). The first call to GetLine reads the first line of text from the file. After reading a line, GetLine repositions the file pointer to the next line. The second call to GetLine reads the second line, and so forth. GetLine strips the carriage return and line feed characters from the end of the line it returns.

When GetLine has read all the lines in a file, it returns an end-of-file error. If you open a file in append mode, the GetLine function fails if you call it because the file pointer is at the end of the file. The function also fails if the file specified by `nvFileHandle` was opened in a binary mode.

The maximum size of a line is 4,096 characters. To read multiple lines from a file, use a separate GetLine call for each line or place the GetLine statement in a loop.

**Tip** ▪ To write to a text file, use the **WriteLine** function. WriteLine always produces lines that have a carriage return and line feed character combination at the end of the line.

### Syntax

```
GetLine ( nvFileHandle, svLine );
```

## Parameters

**Table 165** ▪ GetLine Parameters

| Parameter           | Description                                                                |
|---------------------|----------------------------------------------------------------------------|
| <b>nvFileHandle</b> | Specifies the handle of a file that has been opened by a call to OpenFile. |
| <b>svLine</b>       | Returns a line of text from the file specified by nvFileHandle.            |

## Return Values

**Table 166** ▪ GetLine Return Values

| Return Value  | Description                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully retrieved a line of text from an open text file.                                                                            |
| <b>&lt; 0</b> | Indicates that the function failed due to an end-of-file error or another error condition. This condition also indicates GetLine has read all the lines in the file. |

## GetLine Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the GetLine function.
*
* GetLine is called in this script to read a text file line by
* line.
*
* Note: In order for this script to run properly, you must set
*       the preprocessor constants so that they reference an
*       existing text file on the target system.
*
\*-----*/

#define EXAMPLE_FILE "Readme.txt"
#define EXAMPLE_DIR  "C:\\Windows"
#define TITLE_TEXT   "GetLine example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"
```

```

export prototype ExFn_GetLine(HWND);

function ExFn_GetLine(hMSI)
    STRING  szFileName, szPath, szText, svLine;
    NUMBER  nFlag, nFileHandle;
    LIST    listID;
begin

    // Create a list to store lines from the file.
    listID = ListCreate (STRINGLIST);

    // Set the file mode to normal.
    OpenFileMode (FILE_MODE_NORMAL);

    // Open the file for editing.
    OpenFile (nFileHandle, EXAMPLE_DIR, EXAMPLE_FILE);

    // Get lines from the file into the list.
    while (GetLine (nFileHandle, svLine) = 0)
        ListAddString (listID, svLine, AFTER);
    endwhile;

    // Close the file.
    CloseFile (nFileHandle);

    // Display the list.
    SdShowInfoList (TITLE_TEXT, EXAMPLE_FILE, listID);

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## GetMemFree

The **GetMemFree** function is obsolete and should not be used. This function always returns 1048576.

### Syntax

```
GetMemFree ( );
```

---

**Tip** ▪ To determine the amount of actual physical memory available on the target system, call [GetSystemInfo](#).

## GetObject

The **GetObject** function initializes the szObjectName object and returns a reference that can be assigned to a variable of type OBJECT by using the set keyword. To get a reference to a new or existing COM object (as Visual Basic's GetObject function does), call CoGetObject.

**Tip** ▪ To check whether the object was initialized successfully, call the *IsObject* function.

## Syntax

```
GetObject ( szObjectName );
```

## Parameters

**Table 167** ▪ GetObject Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szObjectName</b> | <p>Specifies the name of the InstallShield object to be initialized as that name is displayed in the Features view, for example:</p> <p>"New ATL 3.0"</p>  <p><b>Note</b> ▪ To ensure that the correct InstallShield object is initialized, give each InstallShield object in your project a unique name.</p> <p>If szObjectName is set to a null string (""), in an object project GetObject returns a reference to the object that is calling it (in a setup project GetObject returns an invalid reference).</p> <p>Setting szObjectName to a null string is useful for reading and writing object properties within the object itself. For example, the following code displays the current status description for the object:</p> <pre>OBJECT oThis;  set oThis = GetObject(""); if( IsObject( oThis ) ) then     MessageBox( oThis.Status.Description, INFORMATION ); endif;</pre> |

## Return Values

A reference that can be assigned to a variable of type OBJECT by using the set keyword.

# GetObjectByIndex

**Project** ▪ This information applies to InstallScript projects.

The **GetObjectByIndex** function finds the setup's or object's subobject that is specified by nIndex and returns a reference that can be assigned to a variable of type OBJECT by using the set keyword.

## Syntax

```
GetObjectByIndex ( nIndex );
```

## Parameters

**Table 168** ▪ GetObjectByIndex Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nIndex</b> | Specifies the index of a subobject. Index numbers start at one (1); if an object passes zero (0) as the argument to GetObjectByIndex, the function returns a reference to the object or setup that is calling the function rather than any subobject. (This is the same as calling GetObject("").) If a setup calls GetObjectByIndex(0), the reference that is returned does not contain any meaningful information. |

## Return Values

A reference that can be assigned to a variable of type OBJECT by using the set keyword.

## Additional Information

To check whether the object was initialized successfully, call the IsObject function.

To get the number of subobjects contained by the object or setup, call [GetObjectCount](#).

# GetObjectCount

**Project** ▪ This information applies to InstallScript projects.

The **GetObjectCount** function returns the number of subobjects contained by the object or setup.

## Syntax

```
GetObjectCount ( );
```

## Parameters

None

## Return Values

**Table 169** ▪ GetObjectCount Return Values

| Return Value              | Description                                               |
|---------------------------|-----------------------------------------------------------|
| <b>&gt;= 0</b>            | The number of subobjects.                                 |
| <b>&lt; ISERR_SUCCESS</b> | GetObjectCount cannot determine the number of subobjects. |

## Additional Information

To get a reference to a subobject that is specified by its index within the setup or object, call [GetObjectByIndex](#).

# GetProfInt

The **GetProfInt** function retrieves an integer from an .ini file. GetProfInt works like the Windows API GetPrivateProfileInt with the nDefault parameter specified as 0.

## Syntax

```
GetProfInt ( szFileName, szSectionName, szKeyName, nvValue );
```

## Parameters

**Table 170** ■ GetProfInt Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>    | Specifies the name of the .ini file from which to get the current integer value of a key. If szFileName is unqualified (that is, if a drive designation and path are <i>not</i> included), InstallShield searches for the file in the Windows folder.                                                                                                                                                                                                                                     |
| <b>szSectionName</b> | Specifies the name of the .ini file section to search for szKeyName. The section name should not be enclosed within delimiting brackets ( [ ] ). The search for this name is not case-sensitive.                                                                                                                                                                                                                                                                                          |
| <b>szKeyName</b>     | Specifies the key whose integer value is to be returned in nvValue. The search for this key is not case-sensitive.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>nvValue</b>       | Returns an integer value currently assigned to szKeyName. Due to limitations of the GetPrivateProfileInt function, this function can return only a 16-bit value from the profile. Therefore, the maximum value that can be returned is 65,535; larger values may not be returned correctly. If you need to return a larger value, use the general file handling functions, such as FileGrep and FileInsertLine, and then convert the returned string into an integer by calling StrToNum. |

## Return Values

GetProfInt always returns 0.

## Additional Information

- As with the Windows API function **GetPrivateProfileInt**, no error is returned if an error occurs because the file, section, or key name cannot be found. Instead, nvValue will contain 0. For that reason, it is not possible to distinguish between an error and a returned value of zero. To distinguish between zero and an error, call **GetPrivateProfileInt** directly and specify an alternate default value.
- Some calls to **GetPrivateProfileInt**—and therefore to **GetProfInt**—are mapped automatically to the Windows registry instead of the profile.

## GetProfInt Example

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the GetProfInt function.
```

```

*
* GetProfInt is called to retrieve the value of a key in
* the file specified by EXAMPLE_INI.
*
* Note: Before running this script, create a file called
*       ISExample.ini in the root of drive C. Include the
*       following lines in that file.
*
*       [ISExample]
*       ISKey=100
*
\*-----*/

#define EXAMPLE_INI "C:\\ISExample.ini"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetProfInt(HWND);

function ExFn_GetProfInt(hMSI)
    STRING szSectionName, szKeyName;
    NUMBER nvValue;
begin

    szSectionName = "ISExample";
    szKeyName      = "ISKey";

    // Get the value of szKeyName under the szSectionName section.
    GetProfInt (EXAMPLE_INI, szSectionName, szKeyName, nvValue);

    sprintfBox (INFORMATION, "GetProfInt Example",
               "The value of %s is: %d.", szKeyName, nvValue);

end;

```

## GetProfSectionKeyCount

**Project** ▪ This information applies to InstallScript projects.

The **GetProSectionKeyCount** function returns the number of keys in the section specified by szSectionName in the initialization file specified by szFilename.

### Syntax

```
GetProfSectionKeyCount ( szFilename, szSectionName );
```

## Parameters

**Table 171** ▪ GetProfSectionKeyCount Parameters

| Parameter            | Description                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFilename</b>    | Specifies the fully qualified name of the .ini file in which to count the keys.                                                                                                                     |
| <b>szSectionName</b> | Specifies the name of the .ini file section in which to count the keys. The section name should not be enclosed within delimiting brackets ( [ ] ). The search for this name is not case-sensitive. |

## Return Values

**Table 172** ▪ GetProfSectionKeyCount Return Values

| Return Value              | Description                                                                                                                                                                                                                                     |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>X</b>                  | The number of keys in the specified section of the specified file.                                                                                                                                                                              |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function could not determine the number of keys.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

# GetProfString

The **GetProfString** function retrieves a profile string from the specified .ini file. GetProfString works like the Windows API GetPrivateProfileString.

**Note** ▪ *GetProfString uses the functions provided by your operating environment's API to access the .ini file. Because of this, InstallShield's functionality might be limited by the operating environment.*

## Syntax

```
GetProfString ( szFileName, szSectionName, szKeyName, svResult );
```

## Parameters

**Table 173** ▪ GetProfString Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>    | Specifies the name of the .ini file from which to get the current value of a key. If szFileName is unqualified (that is, if a drive designation and path are <i>not</i> included), InstallShield searches for the file in the Windows folder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>szSectionName</b> | <p>Specifies the name of the .ini file section to search for szKeyName. The section name should not be enclosed within delimiting brackets ( [ ] ). The search for this name is not case-sensitive. To obtain a list of all section names in the initialization file, pass a null string ("" ) in this parameter.</p> <p> <b>Tip</b> ▪ To obtain a list of all section names in the initialization file, pass a null string ("" ) in szSectionName. The section names, delimited by null characters, are returned in the parameter svResult. svResult must be long enough to accept all of the section names. Use the StrGetTokens function to extract the individual section names from this string.</p> |
| <b>szKeyName</b>     | <p>Specifies the key whose value is to be returned in svResult. The search for this key is not case-sensitive. To obtain a list of all key names in the section, pass a null string ("" ) in this parameter.</p> <p> <b>Tip</b> ▪ To obtain a list of all key names in the section specified by szSectionName, pass a null string ("" ) in szKeyName. The key names, delimited by null characters, are returned in the parameter svResult. svResult must be long enough to accept all of the key names. Use the StrGetTokens function to extract the individual key names from this string.</p>                                                                                                         |
| <b>svResult</b>      | If szSectionName specifies a section name and szKeyName specifies a key name, the value of that key is returned in this parameter. If szSectionName specifies a null string ("" ), all of the section names are returned in svResult. If szKeyName specifies a null string ("" ), all of the key names in the section specified szSectionName are returned in svResult.                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Return Values

**Table 174** ▪ GetProfString Return Values

| Return Value  | Description                                                          |
|---------------|----------------------------------------------------------------------|
| <b>0</b>      | GetProfString successfully returned the value of the profile string. |
| <b>&lt; 0</b> | GetProfString was unable to return the value.                        |

**Table 174** ■ GetProfString Return Values (cont.)

| Return Value | Description                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| -2           | The length of the key's value exceeded 2048 characters, which is the maximum number of characters that can be returned in svResult by GetProfString. |

## GetProfString Example

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the functions AddProfString and GetProfString.
*
* This script adds a profile string to a file; then it
* retrieves and displays the string that was added.
*
* Note: The first time you run this script, it will create a
*       file named ISExempl.ini in the root of drive C. You
*       may delete that file when you have finished analyzing
*       this script.
*
\*-----*/

#define EXAMPLE_INI "C:\\ISExempl.ini"

// The new section, key, and value to add to the file.
#define NEW_SECTION "New Section"
#define NEW_KEY      "New Key"
#define NEW_VALUE    "Test"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetProfString(HWND);

function ExFn_GetProfString(hMSI)
    STRING svResult;
begin
    // Add the profile string to the file.
    if (AddProfString (EXAMPLE_INI, NEW_SECTION, NEW_KEY, NEW_VALUE) != 0) then
        // Display an error message if the string could not be added.
        MessageBox ("AddProfString failed.", SEVERE);
    else
        // Retrieve the value of a key from the file.
        if (GetProfString (EXAMPLE_INI, NEW_SECTION, NEW_KEY, svResult) != 0) then

```

```

        // Display an error message if the string could not be retrieved.
        MessageBox ("GetProfString failed.", SEVERE);
    else
        // Display the key and its current value.
        MessageBox (NEW_KEY + "=" + svResult, INFORMATION);
    endif;
endif;

end;

```

## GetProfStringList

The **GetProfStringList** function retrieves lists of key names and string values from the specified section of the specified initialization file.

### Syntax

```
GetProfStringList ( szFileName, szSectionName, listKeyNames, listValues );
```

## Parameters

**Table 175** ▪ GetProfStringList Parameters

| Parameter            | Description                                                                                                                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>    | Specifies the name of the .ini file from which to get the key names and string values. If szFileName is unqualified (that is, if a drive designation and path are not included), InstallShield searches for the file in the Windows folder. |
| <b>szSectionName</b> | Specifies the name of the .ini file section to search for the key names and string values. The section name should not be enclosed within delimiting brackets ( [ ] ). The search for this name is not case-sensitive.                      |
| <b>listKeyNames</b>  | Returns a list of key names. The string list identified by listKeyNames must already have been initialized by a call to ListCreate.                                                                                                         |
| <b>listValues</b>    | Returns a list of string values. The string list identified by listValues must already have been initialized by a call to ListCreate.                                                                                                       |

## Return Values

**Table 176** ▪ GetProfStringList Return Values

| Return Value                   | Description                                                                                                                  |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS (0)</b> | Indicates that the function successfully read the section and inserted key names and string values into the specified lists. |
| <b>&lt; ISERR_SUCCESS (0)</b>  | Indicates that the function could not read the section or insert key names and string values into the specified lists.       |

## Additional Information

**GetProfStringList** calls the Windows API **GetPrivateProfileSection** and specifies a 32 KB buffer for the data. Therefore, the function returns only the first 32 KB of data from the section. An installation that needs to handle sections with more than 32 KB of data should call the Windows API **GetPrivateProfileSection** directly and specify a larger buffer size (and parse the returned information manually).

## GetProfStringList Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the function GetProfStringList.
 *
 * This script retrieves keys and their values from an
 * initialization file.
 *-----*/
```

```

    if (nVal = END_OF_LIST) then
        MessageBox("No keys found in [" + SECTION + "]", WARNING);
    else
        ListGetFirstString (listKeyValues, svKeyVal);

        repeat
            // Display the keys and their values.
            MessageBox(svKeyName + "=" + svKeyVal, INFORMATION);

            nVal = ListGetNextString (listKeyNames, svKeyName);
            if !(nVal = END_OF_LIST) then
                ListGetNextString (listKeyValues, svKeyVal);
            endif;

        until nVal = END_OF_LIST;

    endif;
endif;

end;

```

## GetShortcutInfo

The **GetShortcutInfo** function checks for the existence of a specific shortcut or subfolder name. If the InstallScript engine finds the shortcut or subfolder, **GetShortcutInfo** returns its attributes. The attributes include the product's command line, working directory, icon path, shortcut key, and minimize flag.

To use **GetShortcutInfo**, enter information in the parameters szShortcutFolder and szName. The InstallScript engine fills the remaining parameters with the shortcut's or subfolder's attributes.

### Syntax

```
GetShortcutInfo (szShortcutFolder, szName, svCmdLine, svWrkDir, svIconPath, nvIconIndex, svShortCutKey,
nvMinimizeFlag);
```

## Parameters

**Table 177** ▪ GetShortcutInfo Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szShortcutFolder</b> | <p>Specify the name of the folder that contains the shortcut or subfolder. You can specify a fully qualified path for szShortcutFolder, such as:</p> <pre>"C:\\ProgramData\\Microsoft\\Windows\\Start Menu\\Programs\\Games"</pre> <p>If szShortcutFolder is null, <b>GetShortcutInfo</b> searches the default Programs directory. If you do not specify an absolute path (a path that includes a drive specification, for example, "C:\\Program Files\\AppName") for szShortcutFolder, <b>GetShortcutInfo</b> searches for a subfolder under the default Programs directory; the location depends on the value of the InstallScript variable ALLUSERS, as well as the version of Windows on the target system.</p> <p>You can also use an InstallScript system variable:</p> <ul style="list-style-type: none"> <li>● <b>FOLDER_DESKTOP</b>—Queries items in the Desktop folder.</li> <li>● <b>FOLDER_STARTUP</b>—Queries items in the Startup menu.</li> <li>● <b>FOLDER_STARTMENU</b>—Queries items in the Start menu.</li> <li>● <b>FOLDER_PROGRAMS</b>—Queries items in the Start\\Programs menu.</li> </ul> <p>Or you could use a relative path, such as:</p> <pre>FOLDER_PROGRAMS ^ "ACCESSORIES\\GAMES"</pre> |
| <b>szName</b>           | Specify the name of the shortcut or subfolder for which you are looking.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>svCmdLine</b>        | The function returns either the command line of the item's executable file or the complete path to the subfolder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>svWrkDir</b>         | The function returns the full path of the working directory of the program item. (Not applicable if szName is a subfolder.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>svIconPath</b>       | The function returns the full path and file name of the .ico file or .exe file. (Not applicable if szName is a subfolder.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>nvIconIndex</b>      | The function returns the index of the icon that is used for the shortcut. (Not applicable if szName is a subfolder.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>svShortCutKey</b>    | The function returns the item's shortcut key. (Not applicable if szName is a subfolder.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 177** ■ GetShortcutInfo Parameters (cont.)

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvMinimizeFlag</b> | <p>The function returns one of the following constants, indicating whether an application window is minimized when first displayed:</p> <ul style="list-style-type: none"> <li>● <b>NULL</b>—Indicates that the application's window is not minimized upon startup.</li> <li>● <b>RUN_MINIMIZED</b>—Indicates that the application's window is minimized upon startup.</li> </ul> <p>(Not applicable if szName is a subfolder.)</p> |

## Return Values

**Table 178** ■ GetShortcutInfo Return Values

| Return Value         | Description                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IS_ITEM (0)</b>   | Indicates szName is a shortcut in szShortcutFolder.                                                                                                                                                                                                              |
| <b>IS_FOLDER (1)</b> | Indicates szName is a subfolder in szShortcutFolder.                                                                                                                                                                                                             |
| <b>&lt; 0</b>        | <p>Indicates that the function was unable to find the shortcut or subfolder name.</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

## Additional Information

The location of the Start menu is different under different languages. The InstallScript engine automatically selects the correct path.

## GetShortcutInfo Example

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the GetShortcutInfo function.
*
* GetShortcutInfo is called to find the attributes of a target
* file or subfolder.
*
* Note: Before running this script, set the defined constants
*       FOLDER_NAME and SHORTCUT so that they reference an

```

```

*      existing folder name and shortcut.
*
/*-----*/
// Define constants to reference the shortcut or folder name.
#define FOLDER_NAME  "C:\\Windows\\Start Menu\\Programs"
#define SHORTCUT     "InstallShield"

function OnFirstUIAfter()

    szMsg   = "The following are attributes of the item:";
    SdShowInfoList (szTitle, szMsg, listInfo);

    // Destroy the list.
    ListDestroy (listID);

end;

```

## GetStatus

**Project** ▪ The **GetStatus** function applies to *InstallScript* Object projects.

The **GetStatus** function retrieves the current status of the object; that is, the current value of `Status.Number`.

**Tip** ▪ To retrieve additional information or to retrieve the status of an object from the installation that contains the object, use the object's *Status* object.

### Syntax

```
number GetStatus();
```

### Parameters

**GetStatus** takes no parameters.

### Return Values

**GetStatus** returns the status of the object.

## GetSystemInfo

The **GetSystemInfo** function retrieves information about the target system. **GetSystemInfo** collects the information that it returns by using the Windows API.

### Syntax

```
GetSystemInfo ( nItem, nvResult, svResult );
```

## Parameters

**Table 179** ▪ GetSystemInfo Parameters

| Parameter       | Description                                             |
|-----------------|---------------------------------------------------------|
| <b>nltem</b>    | Specifies the type of information to retrieve.          |
| <b>nvResult</b> | Returns system information in the form of numeric data. |
| <b>svResult</b> | Returns system information in the form of string data.  |

The following table contains a list of constants that you can pass in the **nltem** parameter to retrieve system information. When using certain constants (such as `DISK_TOTALSPACE_EX`), you must specify additional information in the parameters **nvResult** and/or **svResult** before calling the function.

**Table 180** ▪ nltem Options

| nltem Option       | nvResult Returns                                                                                                                                                                                                                                                                                           | svResult Returns                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <b>BOOTUPDRIVE</b> | The ID of the bootup drive, where 1= A:, 2 = B:, 3 = C:. It is possible to convert this number to the appropriate drive letter by adding 64 (DECIMAL) to the value and then setting a string variable to this value. Use the following syntax to convert:<br><br><code>svResult[0] = 64 + nvResult;</code> | Returns the drive designation (the drive letter followed by a colon) of the bootup drive. |
| <b>CDROM</b>       | TRUE or FALSE Indicates whether a CD-ROM is available.                                                                                                                                                                                                                                                     | Not applicable                                                                            |
| <b>COLORS</b>      | Returns the number of colors available on the user's system. The result is retrieved from the video driver on the target system, rather than from the monitor card. If the card can support 256 colors but the driver can handle only 16 colors, the number of colors returned is 16.                      | Not applicable                                                                            |

Table 180 ■ nltem Options (cont.)

| nltem Option              | nvResult Returns                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | svResult Returns                                                                                                                                                                                                                                                                                                          |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CPU</b>                |  <p><b>Note</b> ■ This parameter is deprecated. Use the structure members of <i>SYSPROCESSORINFO</i> to determine the processor type.</p> <p>One of the following constants is returned:</p> <ul style="list-style-type: none"> <li>● <b>IS_UNKNOWN</b>—The user's CPU is unknown.</li> <li>● <b>IS_386</b>—The user has a 386 processor.</li> <li>● <b>IS_486</b>—The user has a 486 processor.</li> <li>● <b>IS_PENTIUM</b>—The user has a PENTIUM processor.</li> <li>● <b>IS_ALPHA</b>—The user has an ALPHA processor.</li> </ul> | Not applicable                                                                                                                                                                                                                                                                                                            |
| <b>DATE</b>               | Not applicable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | The current system date in the format MM-DD-YYYY. Leading zeroes are suppressed in the month and day fields.                                                                                                                                                                                                              |
| <b>DISK_TOTALSPACE</b>    |  <p><b>Note</b> ■ This parameter is obsolete. Use the parameters available with the <i>GetDiskInfo</i> function instead.</p> <p>Returns the total capacity of the disk drive specified in svResult. The maximum value returned is 2 GB. Total disk space greater than that still returns as 2 GB.</p>                                                                                                                                                                                                                                | The letter of the drive. Note that this parameter is passed to the function; that is, you must assign a value to svResult <i>before</i> calling GetSystemInfo. Also note that you must include the colon (:) after the drive letter; otherwise the function will fail. You can also specify a UNC path in this parameter. |
| <b>DISK_TOTALSPACE_EX</b> |  <p><b>Note</b> ■ This parameter is obsolete. Use the parameters available with the <i>GetDiskInfo</i> function instead.</p> <p>Specifies the measurement unit; pass one of the following predefined constants in this parameter: BYTES, KBYTES, MBYTES or GBYTES. Returns the total capacity of the disk drive specified in svResult.</p>                                                                                                                                                                                           | The letter of the drive. Note that this parameter is passed to the function; that is, you must assign a value to svResult <i>before</i> calling GetSystemInfo. Also note that you must include the colon (:) after the drive letter; otherwise the function will fail. You can also specify a UNC path in this parameter. |

Table 180 ■ nItem Options (cont.)

| nItem Option          | nvResult Returns                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | svResult Returns                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DRIVE</b>          |  <p><b>Note</b> ■ This parameter is obsolete. Use the parameters available with the <i>GetDiskInfo</i> function instead.</p> <p>Returns the type of the drive specified in svResult. One of the following constants is returned:</p> <ul style="list-style-type: none"> <li>● <b>IS_UNKNOWN</b>—Target drive is unknown.</li> <li>● <b>IS_REMOVABLE</b>—Target drive is a floppy drive.</li> <li>● <b>IS_FIXED</b>—Target drive is a fixed drive.</li> <li>● <b>IS_CDROM</b>—Target drive is a CD-ROM drive.</li> <li>● <b>IS_REMOTE</b>—Target drive is a network drive.</li> </ul> | <p>The letter of the drive followed by a colon (:). Note this parameter is passed to the function; that is, you must assign a value to svResult <i>before</i> calling <i>GetSystemInfo</i>.</p> <p>Due to operating system limitations, UNC paths are not supported for svResult. If you pass a UNC path in svResult, the function returns IS_UNKNOWN.</p> |
| <b>EXTENDEDMEMORY</b> | <p>Returns the <i>total</i> amount of memory installed on the machine. Due to operating system limitations, the value returned may be slightly different than the actual amount of physical memory installed on the system. This value will normally be within 100K (0.1 MB) of the actual value. Note that the value returned is a measurement in kilobytes.</p> <p><i>GetSystemInfo</i> (EXTENDEDMEMORY, ... ) accurately returns the amount of extended memory up to 2 terabytes (TB). If a system has more than 2 TB of extended memory, 2 TB is returned.</p>                                                                                                    | Not applicable                                                                                                                                                                                                                                                                                                                                             |
| <b>LANGUAGE</b>       | <p>The InstallScript language constants for the target system are returned in this parameter. For more information, see <i>Creating Multilingual Installations</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <p>The equivalent language name string for the language constant returned in nvResult is returned in this parameter.</p>                                                                                                                                                                                                                                   |

**Table 180** ▪ nItem Options (cont.)

| nItem Option              | nvResult Returns                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | svResult Returns                                |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| <b>OS</b>                 |  <p><b>Note</b> ▪ This parameter is deprecated. Use the WIN9X.bWin9X or WINNT.bWinNT members of the <b>SYSINFO</b> structure variable to obtain operating system information.</p> <p>You can conditionally install some or all of your product based upon operating system by using conditional logic for components, features, and custom actions. For more information, see Building Conditional Statements.</p> | Not applicable                                  |
| <b>OSMAJOR</b>            | This parameter is deprecated. Use the nOSMajor member of the <b>SYSINFO</b> structure variable to obtain operating system information.                                                                                                                                                                                                                                                                                                                                                              | Not applicable                                  |
| <b>OSMINOR</b>            | This parameter is deprecated. Use the nOSMinor member of the <b>SYSINFO</b> structure variable to obtain operating system information.                                                                                                                                                                                                                                                                                                                                                              | Not applicable                                  |
| <b>PARALLEL</b>           | Returns the number of physical parallel ports available.                                                                                                                                                                                                                                                                                                                                                                                                                                            | Not applicable                                  |
| <b>SERIAL</b>             | Returns the number of physical serial ports available.                                                                                                                                                                                                                                                                                                                                                                                                                                              | Not applicable                                  |
| <b>SYSTEM_DPI</b>         | Returns the system DPI value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Not applicable                                  |
| <b>SYSTEM_DPI_SCALING</b> | Returns the system DPI scaling value.                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Not applicable                                  |
| <b>TIME</b>               | Not applicable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Returns current system time in HH:MM:SS format. |

**Table 180** ■ nItem Options (cont.)

| nItem Option                | nvResult Returns                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | svResult Returns                                                                                                                                                                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VIDEO</b>                | <p>Returns the type of video adapter installed. (InstallShield cannot detect CGA or monochrome video drivers.) One of the following constants is returned:</p> <ul style="list-style-type: none"> <li>● <b>IS_UNKNOWN</b>—The user's video is unknown.</li> <li>● <b>IS_EGA</b>—EGA resolution.</li> <li>● <b>IS_VGA</b>—VGA resolution.</li> <li>● <b>IS_SVGA</b>—Super VGA (800 x 600) resolution.</li> <li>● <b>IS_XVGA</b>—XVGA (1024 x 768) resolution.</li> <li>● <b>IS_UVGA</b>—Greater than 1024 x 768 resolution.</li> </ul> | Not applicable                                                                                                                                                                                                                                                             |
| <b>VIRTUAL_MACHINE_TYPE</b> | <p>Not applicable</p> <p>This constant returns its value through the function return.</p> <p>For more information, see <a href="#">Detecting Whether the Installation Is Being Run on a Virtual Machine</a>.</p>                                                                                                                                                                                                                                                                                                                      | Not applicable                                                                                                                                                                                                                                                             |
| <b>VOLUMELABEL</b>          | Not applicable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <p>Pass the drive designation—the drive letter followed by a colon—of the disk whose volume label you want to retrieve. The volume label of the specified drive is then returned in this parameter. If the drive has no volume label, a null string ("" ) is returned.</p> |
| <b>WINMAJOR</b>             | <p>This parameter is deprecated. Use the nWinMajor member of the <b>SYSINFO</b> structure variable to obtain operating system information.</p>                                                                                                                                                                                                                                                                                                                                                                                        | Not applicable                                                                                                                                                                                                                                                             |
| <b>WINMINOR</b>             | <p>This parameter is deprecated. Use the nWinMinor member of the <b>SYSINFO</b> structure variable to obtain operating system information.</p>                                                                                                                                                                                                                                                                                                                                                                                        | Not applicable                                                                                                                                                                                                                                                             |

## Return Values

**Table 181** ▪ GetSystemInfo Return Values

| Return Value                | Description                                                                                                                                                                                                                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IS_VM_TYPE_HYPERV</b>    | <p>The installation is running on a Microsoft Hyper-V machine.</p> <p><b>GetSystemInfo</b> may return this value if VIRTUAL_MACHINE_TYPE was passed to nItem. For more information, see Detecting Whether the Installation Is Being Run on a Virtual Machine.</p>                                                  |
| <b>IS_VM_TYPE_NONE</b>      | <p>No virtual machine has been detected.</p> <p><b>GetSystemInfo</b> may return this value if VIRTUAL_MACHINE_TYPE was passed to nItem. For more information, see Detecting Whether the Installation Is Being Run on a Virtual Machine.</p>                                                                        |
| <b>IS_VM_TYPE_VMWARE</b>    | <p>The installation is running on a VMware product such as VMware Player, VMware Workstation, or VMware Server.</p> <p><b>GetSystemInfo</b> may return this value if VIRTUAL_MACHINE_TYPE was passed to nItem. For more information, see Detecting Whether the Installation Is Being Run on a Virtual Machine.</p> |
| <b>IS_VM_TYPE_VIRTUALPC</b> | <p>The installation is running on a Microsoft Virtual PC machine.</p> <p><b>GetSystemInfo</b> may return this value if VIRTUAL_MACHINE_TYPE was passed to nItem. ## GetSystemInfo Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the GetSystemInfo function.
```

```

*
* This script uses many of the constants available for
* GetSystemInfo and tests for all possible return values.
* The results are displayed in a dialog.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetSystemInfo(HWND);

SdShowInfoList (szTitle, szMsg, listInfo);

ListDestroy(listInfo);

end;

```

## GetTempFileNamesIS

The **GetTempFileNamesIS** function calls the Windows API **GetTempFileName** to create a temporary file and perform related actions. Note that unlike the Windows API **GetTempFileName**, **GetTempFileNamesIS** creates the folder specified by `szPathName` if it does not already exist. Note that as with the **CreateDir** function, the newly created folder or folders are not logged for uninstallation.

### Syntax

```

GetTempFileNameIS( byval string szPathName, byval string szPrefixString, byval number nUnique, byref
    string svTempFileName, byval number nOptions );

```

## Parameters

**Table 182** ▪ GetTempFileNameIS Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>svTempFileName</b> | <p>Specifies the value for the lpTempFileName parameter of the Windows API <a href="#">GetTempFileName</a>.</p> <div data-bbox="683 884 721 926" data-label="Image"> </div> <p><b>Note</b> ▪ InstallScript strings are automatically <code>_MAX_PATH</code> or greater in length. Therefore, there is no need to manually size this string.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>nOptions</b>       | <p>Specifies an InstallScript-specific option. Pass any of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>GTFIS_OPTION_NONE</b>—No InstallScript-specific options. This is the default option.</li> <li>● <b>GTFIS_OPTION_DONT_RESOLVE_TEXTSUBS</b>—Do not call <b>TextSubSubstitute</b> to resolve text substitutions in <b>szPathName</b> and <b>szPrefixString</b>.</li> <li>● <b>GTFIS_OPTION_DONT_CREATE_DIR</b>—Do not create the directory specified by <b>szPathName</b> if it does not already exist. Note that if this option is specified and <b>szPathName</b> does not exist, the function fails.</li> <li>● <b>GTFIS_OPTION_DELETE_TEMP_FILE</b>—Delete the created temporary file before returning. (Note that this option is useful only if you specify <b>nUnique</b> such that the function creates a temporary file. For more information, see <a href="#">GetTempFileName Function</a>.) The function does not return failure if the temporary file cannot be deleted.</li> </ul> |

## Return Values

**Table 183** ▪ GetTempFileNameIS Return Values

| Return Value               | Description                                     |
|----------------------------|-------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was not successful. |

## GetTrueTypeFontFileInfo

The **GetTrueTypeFontFileInfo** function returns in svResult information about the TrueType font file that is specified by szTrueTypeFontFile.

### Syntax

```
GetTrueTypeFontFileInfo ( szTrueTypeFontFile, nInfo, nLanguage, svResult );
```

## Parameters

**Table 184** • GetTrueTypeFontFileInfo Parameters

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTrueTypeFontFile</b> | Specifies the fully qualified file name of the TrueType font file from which you want information. Note that non-TrueType files such as .fon and .fot files are not supported by this function, nor are TrueType collection files (.ttc files) supported.                                                                                                      |
| <b>nInfo</b>              | Specifies the information to be returned in svResult. Pass one of the following constants in this parameter: <ul style="list-style-type: none"> <li>● <b>TTFONTFILEINFO_FONTTITLE</b>—Specifies the font's title.</li> <li>● <b>name ID</b>—You can use a name ID to get <a href="#">font information</a>.</li> </ul>                                          |
| <b>nLanguage</b>          | Specifies the language of the string to be returned in svResult. Pass a predefined language constant, numeric language ID, the system variable <b>SELECTED_LANGUAGE</b> , or 0 (zero)—which has the same effect as passing <b>SELECTED_LANGUAGE</b> —in this parameter. Note that not all information for a particular font may be available in all languages. |
| <b>svResult</b>           | Returns the font information that you specified in nInfo. An ANSI (non-Unicode) string is returned even if the data in the file is stored in a Unicode format.                                                                                                                                                                                                 |

## Return Values

**Table 185** • GetTrueTypeFontFileInfo Return Values

| Return Value               | Description                                                                   |
|----------------------------|-------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully retrieved the requested information. |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to retrieve the requested information. |

# GetUpdateStatus

The **GetUpdateStatus** function is obsolete. If this function is called, it returns FALSE.

## Syntax

```
BOOL GetUpdateStatus();
```

# GetUpdateStatusReboot

The **GetUpdateStatusReboot** function is obsolete. If this function is called, it returns FALSE.

## Syntax

```
BOOL GetUpdateStatusReboot();
```

# GetValidDrivesList

The **GetValidDrivesList** function retrieves a list of all the drives attached to the target system that meet a certain criterion. This criterion includes the type of drive and the minimum amount of space on the drive. If a drive door is open, the drive name is still inserted into the list.

## Syntax

```
GetValidDrivesList (listID, nDriveType, nMinDriveSpace);
```

## Parameters

**Table 186** ▪ GetValidDrivesList Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>         | Returns a list of valid drive letters. The string list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> .                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>nDriveType</b>     | Specifies the type of drive to search for. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>-1</b>—Searches for all drive types.</li> <li>● <b>FIXED_DRIVE</b>—Searches only for fixed drives.</li> <li>● <b>REMOTE_DRIVE</b>—Searches only for remote drives. Remote drives are generally located on a network.</li> <li>● <b>REMOVEABLE_DRIVE</b>—Searches only for removable drives. Floppy drives are removable drives.</li> <li>● <b>CDROM_DRIVE</b>—Searches only for CD-ROM drives.</li> </ul> |
| <b>nMinDriveSpace</b> | Specifies the minimum amount of disk space in bytes that must be free on the drive to allow the drive to be included in the return list. If nMinDriveSpace is less than zero, GetValidDrivesList will not check for the minimum space on the drive. This is useful for floppy drives.                                                                                                                                                                                                                                                                              |

## Return Values

**Table 187** ▪ GetValidDrivesList Return Values

| Return Value  | Description                                                   |
|---------------|---------------------------------------------------------------|
| <b>0</b>      | GetValidDrivesList successfully retrieved the requested list. |
| <b>&lt; 0</b> | GetValidDrivesList was unable to retrieve the list.           |

## Additional Information

- You can specify the type of drive to search for and the minimum amount of disk space that must be available before the drive is listed.
- Network mapping drives can be returned as remote drives. GetValidDrivesList might not return all drives on the network. Those drives designated as mapping drives only are returned.

## GetValidDrivesList Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the GetValidDrivesList function.
*
* GetValidDrivesList is called twice: once to return a list of
* removable drives that have a minimum of 120,000 bytes free,
* then again to return a list of fixed drives that have a
* minimum of 1,000,000 bytes free.
*
\*-----*/

#define TITLE          "GetValidDrivesList Example"
#define MSG_REMOVABLE  "Removable drives with 120,000 bytes free:"
#define MSG_FIXED      "Fixed drives with 1,000,000 bytes free."
#define MSG_ERR        "GetValidDrivesList failed."

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetValidDrivesList(HWND);

function ExFn_GetValidDrivesList(hMSI)
    LIST    listID;
begin

    // Create a list to hold the removable drive names.
    listID = ListCreate (STRINGLIST);

    // Get removable drives with at least 120,000 bytes free.
    if (GetValidDrivesList (listID, REMOVEABLE_DRIVE, 120000) < 0) then
        // Report an error; then terminate.
        MessageBox (MSG_ERR, SEVERE);
        abort;
    else
        // Display the list of removable drives.
        SdShowInfoList (TITLE, MSG_REMOVABLE, listID);
    endif;

    // Destroy the list of removable drives.
    ListDestroy (listID);

    // Create a list to hold the fixed drive names.
    listID = ListCreate (STRINGLIST);

    // Get fixed drives with at least one million bytes free.
    if (GetValidDrivesList (listID, FIXED_DRIVE, 1000000) < 0) then
        // Report an error; then terminate.
```

```

        MessageBox (MSG_ERR, SEVERE);
        abort;
    else
        // Display the list of fixed drives.
        SdShowInfoList (TITLE, MSG_FIXED, listID);
    endif;

end;

```

## GetWCHARArrayFromISStringArray

The **GetWCHARArrayFromISStringArray** function returns a pointer to an array of pointers to Unicode character strings that are contained in the specified array.

### Syntax

```
GetWCHARArrayFromISStringArray ( vArray );
```

### Parameters

**Table 188** ▪ GetWCHARArrayFromISStringArray Parameters

| Parameter     | Description                                             |
|---------------|---------------------------------------------------------|
| <b>vArray</b> | Specifies the string array to which you want a pointer. |

### Return Values

**Table 189** ▪ GetWCHARArrayFromISStringArray Return Values

| Return Value              | Description                                                     |
|---------------------------|-----------------------------------------------------------------|
| <b>pointer</b>            | A pointer to an array of pointers to Unicode character strings. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function failed.                             |

### Additional Information

The **GetWCHARArrayFromISStringArray** function allocates additional memory for the array of pointers and the Unicode character strings. This pointer can be passed to functions that take LPWSTR\* arguments. After you are done with the newly created array, call **DeleteWCHARArray** to delete the array from memory.

If you call **CopyCHARArrayToISStringArray** to write the data from the array of pointers back to the original string array, be careful when modifying strings that are contained in the array. Since the lengths of the strings that are contained in string arrays are managed internally by the installation, if you change the length of a string the entire string will not be copied back to the original array when you call **CopyCHARArrayToISStringArray**.

## GetWindowHandle

The **GetWindowHandle** function gets the handle of the main window of the installation.

## Syntax

```
GetWindowHandle ( nHwndFlag );
```

## Parameters

**Table 190** ▪ GetWindowHandle Parameters

| Parameter        | Description                                                                                                                           |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>nHwndFlag</b> | Specifies the window handle of InstallShield's main window. Pass the predefined constant <code>HWND_INSTALL</code> in this parameter. |

## Return Values

**Table 191** ▪ GetWindowHandle Parameters

| Return Value  | Description                                        |
|---------------|----------------------------------------------------|
| <b>X</b>      | Where X is the handle of the window.               |
| <b>&lt; 0</b> | GetWindowHandle was unable to retrieve the handle. |

## GetWindowHandle Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the GetWindowHandle function.
 *
 * This script starts the setup in a normal window. After three
 * seconds, the window is minimized. Then after another pause,
 * the window is maximized and a message box is displayed.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_GetWindowHandle(HWND);

function ExFn_GetWindowHandle(hMSI)
    NUMBER nHwnd;
    HWND hInstallHwnd;
begin

    // Specify a standard window for this setup.
    Enable (DEFWINDOWMODE);

    // Display the background window.
    Enable (BACKGROUND);
```

```
// Get the setup's window handle.
nHwnd = GetWindowHandle (HWND_INSTALL);

// Wait three seconds.
Delay (3);

// Send system command to minimize the window.
SendMessage (nHwnd, WM_SYSCOMMAND, SC_MINIMIZE, 0);

// Wait three seconds.
Delay (3);

// Send system command to maximize the window.
SendMessage (nHwnd, WM_SYSCOMMAND, SC_MAXIMIZE, 0);

// Display a message.
MessageBox ("Demo completed.", INFORMATION);

end;
```

# Built-In Functions (H-P)

For a list of functions by category, see [Built-In Functions by Category](#).

## Handler

The **Handler** function is obsolete. Use [HandlerEx](#) instead.

## HandlerEx

The **HandlerEx** function creates custom handlers for events such as the Help accelerator key (F1) and the Cancel button.

If the end user presses the F1 key, the currently defined HELP handler is executed. If the user presses the Cancel button, the currently defined EXIT handler is executed. If you have not defined custom HELP or EXIT handlers using the **HandlerEx** function, the default handlers are executed. The default EXIT handler displays the Exit dialog. The default HELP handler does nothing.

To execute custom handlers defined using **HandlerEx**, the InstallScript engine calls a unique label that is specified in the parameter Label when the nObject event occurs. When the InstallScript engine reaches a return statement in the handler code (under the label), control returns to the statement that would have executed next if the handler label were not called.

Using **HandlerEx**, you can specify custom handling of EXIT or HELP. You can display the **MessageBox**, **SprintfBox**, and **AskYesNo** dialogs inside Exit handlers; however, you cannot display Sd dialogs.

### Syntax

```
HandlerEx (nObject, Label);
```

## Parameters

**Table 1** ▪ HandlerEx Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nObject</b> | <p>Specifies the event to trap. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>EXIT</b>—Specifies that a custom handler is called when the Cancel button is pressed. If you do not define a handler, a default Exit dialog appears when the Cancel button is pressed.</li> <li>● <b>HELP</b>—Specifies that a custom handler is called when the F1 accelerator key is pressed. If you do not define a handler, nothing happens when the F1 accelerator key is pressed.</li> </ul>                                                                                                                          |
| <b>Label</b>   | <p>Specifies the name of the label to which the program should jump if the specified button or accelerator key is pressed. Do not define this label as a numeric value or as a string variable.</p> <p>To cancel a currently defined handler and reinstall the default handler, pass -1 in this parameter. This method is useful in scripts that install a custom handler only for certain processes and then revert to the default handler.</p> <div style="text-align: center;">  </div> <p><b>Caution</b> ▪ Do not define the label name as a numeric value or as a string variable.</p> |

## Return Values

**Table 2** ▪ HandlerEx Return Values

| Return Value  | Description                                       |
|---------------|---------------------------------------------------|
| <b>0</b>      | <b>HandlerEx</b> successfully created the handle. |
| <b>&lt; 0</b> | <b>HandlerEx</b> was unable to create the handle. |

## Additional Information

- The only accelerator available is the F1 function key (Help).
- Help (F1) allows you to launch the help engine or provide other suitable help. When the end user presses the F1 key, the InstallScript engine calls the currently defined Help handler. You can provide any type of help functionality in the Help handler. If you want to provide context-sensitive help, you must keep track of the context in your script.

For example, you can have a string variable that contains a current context string. You can then use that string variable in a switch-case statement inside the Help handler to execute the appropriate Help events based on the value of the context string. You can also test the value of the nSdDialog global variable in your Help handling routine. nSdDialog is set to the dialog ID (as described in `_isres.h` in the *InstallShield*

*Program Files Folder\Script\Isrt\Include folder*) of the currently executing Sd dialog. (When no Sd dialog is executing, nSdDialog is not defined.) You can therefore give the user access to Sd dialog-specific help when an Sd dialog is executing.

- As with Help handlers, you can also define and execute custom and Sd dialog-specific EXIT handlers.

## HandlerEx Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the HandlerEx function.
*
* This script shows how to install error and help handlers in
* an installation.
*
* First, the handlers are installed. Then Sd dialogs are
* displayed to the end user. The handler code is invoked if
* the end user presses F1 (help) or clicks the cancel
* button while the dialogs are displayed.
*
* Note that the script uses the InstallScript Language
* Reference and Help Library help files for demonstration purposes.
* Insert copies of these files (Langref.chm and HelpLib.chm from
* the InstallShield Program Files Folder\Program folder) in the
* Language Independent area of the Support Files/Billboards view.
\*-----*/

// Included header files -----
#include "ifx.h"

export prototype void ExFn_Handler();
prototype OnHelp_Handler();
prototype OnExit_Handler();

// Define help topic IDs
#define HELP_WELCOME 101
#define HELP_REGISTERUSER 102

INT nHelpID;

function void ExFn_Handler()
    STRING svName, svCompany, szMsg;

    endif;
end;

```

# HIBYTE

**Project** ▪ This information applies to InstallScript projects.

The **HIBYTE** function extracts the high-order byte from the 16-bit integer value specified by `shValue`.

## Syntax

```
HIBYTE ( shValue );
```

## Parameters

**Table 3** ▪ HIBYTE Parameters

| Parameter      | Description                                                                  |
|----------------|------------------------------------------------------------------------------|
| <b>shValue</b> | Specifies the 16-bit integer from which you want to extract the higher byte. |

## Return Values

This function returns the high-order byte of the integer.

# HIWORD

The **HIWORD** function extracts and returns the high-order word (upper two bytes) from the 32-bit integer value specified by `lValue`.

InstallShield's **HIWORD** differs from the corresponding C macro in that it uses sign extension. As a result, the high-order bytes of the value returned by **HIWORD** are filled with ones if `lValue` is negative. If necessary, you can use the bitwise AND operator (&) to combine the result with `0xFFFF` to produce a positive value, as shown below:

```
lValue = HIWORD(lValue);
lValue = lValue & 0xFFFF;
```

## Syntax

```
HIWORD ( lValue );
```

Parameters

Table 4 • HIWORD Parameters

| Parameter | Description                                                             |
|-----------|-------------------------------------------------------------------------|
| IValue    | Specifies the 32-bit integer from which to extract the upper two bytes. |

Return Values

HIWORD returns the high-order word (upper two bytes) of IValue.

HIWORD Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates HIWORD and LOWORD.
*
* This example script shows how to use HIWORD and LOWORD to
* to get the low-order word and the high-order word from a value.
\*-----*/

#define TITLE_TEXT "LOWORD/HIWORD Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_HIWORD(HWND);

function ExFn_HIWORD(hMSI)
    STRING  szMsg;
    NUMBER  nData, nLOWORD, nHIWORD;
begin

    nData = 305419896; // hex value: 12345678
    // Get the low-order word, 22136 (hex value: 5678).

    nLOWORD = LOWORD (nData);

    // Get the high-order word, 4660 (hex value: 1234).
    nHIWORD = HIWORD (nData);

    // Display the results.
    szMsg = "LOWORD: %ld\nHIWORD: %ld";
    sprintfBox (INFORMATION, TITLE_TEXT, szMsg, nLOWORD, nHIWORD);
```

```
end;
```

## InstallationInfo

The **InstallationInfo** function is obsolete. Use the [CreateInstallationInfo](#) function instead.

### Syntax

```
InstallationInfo (szCompany, szProduct, szVersion, szProductKey);
```

## Is

The **Is** function retrieves information commonly needed in a script.

### Syntax

```
Is ( nIsFlag, szIsData );
```

## Parameters

**Table 5 • Is Parameters**

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nlisFlag</b> | <p>Specifies the type of information to retrieve. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>BACKBUTTON</b>—Is the Back button that is displayed in some built-in dialogs enabled?</li> <li>• <b>CANCELBUTTON</b>—Is the Cancel button that is displayed in some built-in dialogs enabled?</li> <li>• <b>DOTNETFRAMEWORKINSTALLED</b>—Is a particular version of the .NET Framework or language pack installed? For more information on the predefined values that are supported, see the <a href="#">Additional Information</a> section.</li> <li>• <b>DOTNETSERVICEPACKINSTALLED</b>—Is a particular service pack—or a later version of the service pack—of the .NET Framework installed? For more information on the predefined values that are supported, see the <a href="#">Additional Information</a> section.</li> <li>• <b>DIR_WRITEABLE</b>—Can the installation write to the directory that is specified in szIsData?</li> <li>• <b>FILE_EXISTS</b>—Does the file that is specified in szIsData exist?</li> <li>• <b>FILE_LOCKED</b>—Is the file locked? Note that <b>Is</b> returns TRUE if the file is not accessible because of insufficient privileges.</li> <li>• <b>FILE_WRITEABLE</b>—Can the installation write to the file specified in szIsData?</li> <li>• <b>FONT_AVAILABLE</b>—Is the font with the title that is specified in szIsData installed? Note that the function searches for the font in all character sets. To search in a single character set, call the Windows API function <b>EnumFontFamiliesEx</b>; for details on this function, see Microsoft's Windows API documentation.</li> <li>• <b>FUNCTION_EXPORTED</b>—Does the DLL that is specified in szIsData export the function specified in szIsData? <b>Is</b> returns TRUE if the DLL exists and can be loaded, and if the function is exported. Otherwise, <b>Is</b> returns FALSE.</li> <li>• <b>LANGUAGE_SUPPORTED</b>—(InstallScript and InstallScript MSI projects) Does the installation support the language that is specified in szIsData?</li> <li>• <b>LOGGING</b>—(InstallScript projects only) Is logging of uninstallation information enabled?</li> <li>• <b>MATH_COPROCESSOR</b>—Does a math coprocessor exist in the target system?</li> <li>• <b>NEXTBUTTON</b>—Is the Next button that is displayed by some built-in dialogs enabled? On most dialogs, the Next button is enabled by default.</li> <li>• <b>PATH_EXISTS</b>—Does the path that is specified in szIsData exist?</li> <li>• <b>REGDBREMOTEREGCONNECTED</b>—Is a remote registry currently connected?</li> <li>• <b>REBOOTED</b>—Is the installation running after a reboot?</li> </ul> |

Table 5 • Is Parameters (cont.)

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nIsFlag<br/>(cont.)</b> | <ul style="list-style-type: none"> <li>● <b>SETUP_PACKAGE</b>—(InstallScript projects only) Is the setup running from a self-extracting executable file?<br/><br/>During maintenance mode or during uninstallation, Is(SETUP_PACKAGE, szIsData) returns TRUE if the original installation was a self-extracting executable file (although maintenance or uninstallation runs not from the self-extracting executable file, but from the copy of Setup.exe in the DISK1TARGET folder).</li> <li>● <b>SKIN_LOADED</b>—Is a dialog skin loaded?</li> <li>● <b>URL</b>—Is the string that is specified in szIsData a URL? (That is, does the string begin with "http://" or "https://" or "file://" or "ftp://")?</li> <li>● <b>USER_ADMINISTRATOR</b>—Does the current user have administrator privileges? <b>Is</b> returns TRUE when USER_ADMINISTRATOR is passed in nFlag in all cases, except for some cases on Windows Vista and later systems; on these later systems, <b>Is</b> returns TRUE if the USER_ADMINISTRATOR is passed in nFlag and the SE_GROUP_USE_FOR_DENY_ONLY security identifier (SID) attribute is not set for the group. That is, if the current user is in the Administrators group but that user is running the installation with a standard access token on Windows Vista or later, <b>Is</b> returns FALSE.</li> <li>● <b>USER_INADMINGROUP</b>—Is the current user in the Administrators group? <b>Is</b> returns TRUE for this constant, regardless of whether the SE_GROUP_USE_FOR_DENY_ONLY SID attribute is set for the group (that is, regardless of whether the user with administrative privileges is running the installation with a standard access token).</li> <li>● <b>USER_POWERUSER</b>—Does the current user belong to the Power Users group?</li> <li>● <b>VALID_PATH</b>—Is the path specified in szIsData a legal path? This will not confirm the existence of a path, it will only check its syntax. You can use this constant when you retrieve path information from the user. The function will then check to see if the path information was entered correctly.<br/><br/>A valid URL string meets the following criteria: (1) It begins with <b>http://</b>, <b>https://</b>, or <b>file://</b>. (2) It contains only numbers, letters, and the following characters: ! \$ % &amp; ' ( ) * + - . / \ _</li> </ul> |
| <b>nIsFlag<br/>(cont.)</b> | <ul style="list-style-type: none"> <li>● <b>WEB_BASED_SETUP</b>—(InstallScript projects only) Is the installation being run from the Internet?<br/><br/><br/><b>Note</b> • Is(WEB_BASED_SETUP,szIsData) checks whether the current instance of the installation is being run from the Web. For this reason, when the installation is run from Add or Remove Programs, Is(WEB_BASED_SETUP,szIsData) always returns FALSE, since in that case the installation is always being run from the local files even if the original installation was run from the Web.</li> <li>● <b>WINDOWS_SHARED</b>—Is Microsoft Windows running a shared copy from a network?<br/><br/>A shared copy of Microsoft Windows is installed on a network and has common files that are shared by many users.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 5 • Is Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szIsData</b> | <p>Specifies information that is dependent on the constant that is passed in <code>nlsFlag</code>, as shown below. Note that if the path or file name is enclosed in quotation marks, <b>Is</b> fails. To ensure that the path or file name is not enclosed in quotation marks, call <code>LongPathToQuote(szIsData, FALSE)</code> before calling <b>Is</b>. The following list provides an explanation of what <code>szIsData</code> should contain when each <code>nlsFlag</code> option is specified:</p> <ul style="list-style-type: none"> <li>• <b>DIR_WRITEABLE</b>—<code>szIsData</code> specifies the fully qualified path to be checked.</li> <li>• <b>DOTNETFRAMEWORKINSTALLED</b>—<code>szIsData</code> specifies the version of the .NET Framework or language pack to check. For more information on the predefined values that are supported, see the <a href="#">Additional Information</a> section.</li> <li>• <b>DOTNETSERVICEPACKINSTALLED</b>—<code>szIsData</code> specifies the minimum service pack and version of the .NET Framework to check, in the following format: <p><i>Service Pack Number .NET Version Registry Constant or Path</i></p> <p><i>Service Pack Number</i> indicates the number of the minimum service pack. For the .NET Framework 1.0, the value can be 0 through 3. For the .NET Framework 1.1 and later, all numeric values are supported. Both the service pack number and the pipe character ( ) delimiter must be included; otherwise, the function returns failure.</p> <p><i>.NET Version Registry Constant or Path</i> indicates the registry constant or registry path that shows the version of the .NET Framework to check. For more information on the predefined values that are supported and to learn how the <b>Is</b> function performs the check, see the <a href="#">Additional Information</a> section.</p> </li> <li>• <b>FILE_EXISTS</b>—<code>szIsData</code> specifies the fully qualified file name. You can specify a valid URL in this parameter. To check the validity of a URL, call <code>Is(VALID_PATH, szIsData)</code>.</li> <li>• <b>FILE_LOCKED</b>—<code>szIsData</code> specifies the fully qualified file name.</li> <li>• <b>FILE_WRITEABLE</b>—<code>szIsData</code> specifies the fully qualified file name.</li> <li>• <b>FONT_AVAILABLE</b>—<code>szIsData</code> specifies the font title.</li> <li>• <b>FUNCTION_EXPORTED</b>—<code>szIsData</code> specifies the fully qualified file name of the DLL followed by a pipe character ( ) and the name of the function; for example: <p><i>C:\MyDLLFolder\MyDLL.dll MyFunction</i></p> </li> <li>• <b>LANGUAGE_SUPPORTED</b>—<code>szIsData</code> specifies the path to the <code>Setup.ini</code> file and the language ID, in the following format: <p><i>Path to Setup.ini Language ID</i></p> <p>If the path to <code>Setup.ini</code> is not specified, the current installation is used. If the language ID is not specified, <code>SELECTED_LANGUAGE</code> is used.</p> <p>The language ID should be a four-digit hexadecimal language code, including the 0x prefix. For example, if for English, the value should be 0x0409. To build a string with <code>STANDARD_SELECTED_LANGUAGE</code> in this format, use a statement such as:</p> <pre>Sprintf (szLang, "0x%.04lx", STANDARD_SELECTED_LANGUAGE);</pre> </li> </ul> |

**Table 5** • Is Parameters (cont.)

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szIsData (cont.)</b> | <ul style="list-style-type: none"> <li>● <b>LOGGING</b>—szIsData is ignored.</li> <li>● <b>MATH_COPROCESSOR</b>—szIsData specifies szIsData is ignored.</li> <li>● <b>PATH_EXISTS</b>—szIsData specifies the fully qualified path. You can specify a valid URL in this parameter. To check the validity of a URL, call Is(VALID_PATH, szIsData).</li> <li>● <b>REGDBREMOTEREGCONNECTED</b>—szIsData is ignored.</li> <li>● <b>SETUP_PACKAGE</b>—szIsData is ignored.</li> <li>● <b>SKIN_LOADED</b>—szIsData is ignored.</li> <li>● <b>USER_ADMINISTRATOR</b>—szIsData is ignored.</li> <li>● <b>USER_POWERUSER</b>—szIsData is ignored.</li> <li>● <b>VALID_PATH</b>—szIsData specifies the fully qualified path.</li> <li>● <b>WEB_BASED_SETUP</b>—szIsData is ignored.</li> <li>● <b>WINDOWS_SHARED</b>—szIsData is ignored.</li> </ul> |

## Return Values

**Table 6** • Is Return Values

| Return Value     | Description                                        |
|------------------|----------------------------------------------------|
| <b>TRUE (1)</b>  | Indicates that the answer is true.                 |
| <b>FALSE (0)</b> | Indicates that the answer is false.                |
| <b>&lt; 0</b>    | The Is function was unable to answer the question. |

## Additional Information

### .NET Framework Version and Service Details

The following predefined constants are supported for specifying a particular version of the .NET Framework using DOTNETFRAMEWORKINSTALLED or DOTNETSERVICEPACKINSTALLED:

- **REGDB\_KEYPATH\_DOTNET\_40\_CLIENT**
- **REGDB\_KEYPATH\_DOTNET\_40\_FULL**
- **REGDB\_KEYPATH\_DOTNET\_35**
- **REGDB\_KEYPATH\_DOTNET\_30\_SP**—Use this variable to detect whether the SP1 (or a later service pack) of the .NET Framework 3.0 is installed.
- **REGDB\_KEYPATH\_DOTNET\_30**—Use this variable to detect whether the RTM version of the .NET Framework 3.0 is installed.

- [REGDB\\_KEYPATH\\_DOTNET\\_20](#)
- [REGDB\\_KEYPATH\\_DOTNET\\_11](#)
- [REGDB\\_KEYPATH\\_DOTNET\\_10](#)

**Tip** • Since each of these predefined constants correspond to the appropriate registry path under `HKEY_LOCAL_MACHINE`, you can also specify a registry path directly in `szIsData` for `DOTNETFRAMEWORKINSTALLED` or `DOTNETSERVICEPACKINSTALLED`.

The installation of the .NET Framework 3.0 writes the registry value `InstallSuccess`, with 1 as the value data, in the following registry location:

```
HKEY_LOCAL_MACHINE\Software\Microsoft\NET Framework Setup\NDP\v3.0\Setup\
```

Therefore, `REGDB_KEYPATH_DOTNET_30` is set to that location.

The installations of all other versions of the .NET Framework write the registry value `Install` with a value data of 1 in the following registry location:

```
HKEY_LOCAL_MACHINE\Software\Microsoft\NET Framework Setup\NDP\Version Number\
```

The `REGDB_KEYPATH_DOTNET_35`, `REGDB_KEYPATH_DOTNET_20`, `REGDB_KEYPATH_DOTNET_11`, and `REGDB_KEYPATH_DOTNET_10` constants are set to the appropriate values, based on that path.

Note that the installation of the .NET Framework 3.0 SP1 also writes the registry value `Install` with a value data of 1 in the following registry location:

```
HKEY_LOCAL_MACHINE\Software\Microsoft\NET Framework Setup\NDP\v3.0\
```

Therefore, `REGDB_KEYPATH_DOTNET_30_SP` is set to that location.

If you use the `Is` function with the `DOTNETFRAMEWORKINSTALLED` constant, the function automatically checks for both the `Install` and `InstallSuccess` values. If the `Install` or `InstallSuccess` value exists and its value data is set to 1, `Is` returns `TRUE`. Otherwise, `Is` returns `FALSE`.

The .NET Framework 1.0 service pack installations do not create registry values that indicate the service pack number. Therefore, if you use `DOTNETSERVICEPACKINSTALLED` to test for the .NET Framework 1.0, the `Is` function compares the version of the `mscorlib.dll` file in `FOLDER_DOTNET_10` against known version numbers to determine the service pack:

- SP3 is present if the version of `mscorlib.dll` is 1.0.3705.6018 or later.
- SP2 is present if the version of `mscorlib.dll` is 1.0.3705.288 or later, but earlier than 1.0.3705.6018.
- SP1 is present if the version of `mscorlib.dll` is 1.0.3705.209 or later, but earlier than 1.0.3705.288.
- The original RTM version is present if the version of `mscorlib.dll` is 1.0.3705.0 or later, but earlier than 1.0.3705.209.

If you use `DOTNETSERVICEPACKINSTALLED` to test for any of the other .NET Framework versions, the function compares the `REGDB_VALUENAME_SP` value under the .NET version registry constant or path that is specified in `szIsData` with the service pack number that is specified in `szIsData`. Note that the comparison is an equal-to-or-later-than version comparison; therefore, if you specify a service pack of 2 in `szIsData`, the function returns true whenever service pack 2 or later is installed.

## .NET Framework Language Pack Details

Version 1.1 and later of the .NET Framework includes support for language packs; version 1.0 does not. For version 1.1 and later of the .NET Framework, you can test whether a particular .NET language pack is installed through the DOTNETFRAMEWORKINSTALLED constant by specifying the appropriate .NET version constant and the locale identifier (LCID) of the language (converted to a string). Separate the .NET version constant and the LCID with the caret operator. For example, use the following syntax to test whether the German language pack for .NET Framework 1.1 is installed:

```
NumToStr( szLang, ISLANG_GERMAN_STANDARD );  
REGDB_KEYPATH_DOTNET_11 ^ szLang;
```

As documented by Microsoft, the .NET Framework 1.1 supports the following LCIDs:

**Table 7** • Supported .NET LCIDs

| Language                      | LCID          | Corresponding Is Constant   |
|-------------------------------|---------------|-----------------------------|
| <b>Chinese (Simplified)</b>   | 2052 (0x0804) | ISLANG_CHINESE_SIMPLIFIED   |
| <b>Chinese (Traditional)</b>  | 1028 (0x0404) | ISLANG_CHINESE_TRADITIONAL  |
| <b>Czech</b>                  | 1029 (0x0405) | ISLANG_CZECH_STANDARD       |
| <b>Danish</b>                 | 1030 (0x0406) | ISLANG_DANISH_STANDARD      |
| <b>Dutch</b>                  | 1043 (0x0413) | ISLANG_DUTCH_STANDARD       |
| <b>Finnish</b>                | 1035 (0x040B) | ISLANG_FINNISH_STANDARD     |
| <b>French</b>                 | 1036 (0x040C) | ISLANG_FRENCH_STANDARD      |
| <b>German</b>                 | 1031 (0x0407) | ISLANG_GERMAN_STANDARD      |
| <b>Greek</b>                  | 1032 (0x0408) | ISLANG_GREEK_STANDARD       |
| <b>Hungarian</b>              | 1038 (0x040E) | ISLANG_HUNGARIAN_STANDARD   |
| <b>Italian</b>                | 1040 (0x0410) | ISLANG_ITALIAN_STANDARD     |
| <b>Japanese</b>               | 1041 (0x0411) | ISLANG_JAPANESE_STANDARD    |
| <b>Korean</b>                 | 1042 (0x0412) | ISLANG_KOREAN_STANDARD      |
| <b>Norwegian</b>              | 1044 (0x0414) | ISLANG_NORWEGIAN_BOKMAL     |
| <b>Polish</b>                 | 1045 (0x0415) | ISLANG_POLISH_STANDARD      |
| <b>Portuguese (Brazilian)</b> | 1046 (0x0416) | ISLANG_PORTUGUESE_BRAZILIAN |
| <b>Portuguese (Portugal)</b>  | 2070 (0x0816) | ISLANG_PORTUGUESE_STANDARD  |

**Table 7** ▪ Supported .NET LCIDs (cont.)

| Language       | LCID          | Corresponding Is Constant |
|----------------|---------------|---------------------------|
| <b>Russian</b> | 1049 (0x0419) | ISLANG_RUSSIAN_STANDARD   |
| <b>Spanish</b> | 3082 (0x0C0A) | ISLANG_SPANISH_MODERNSORT |
| <b>Swedish</b> | 1053 (0x041D) | ISLANG_SWEDISH_STANDARD   |
| <b>Turkish</b> | 1055 (0x041F) | ISLANG_TURKISH_STANDARD   |

## Is Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the Is function.
 *
 * The Is function is first called to check if a file is write
 * protected. It is called a second time to check if the
 * directory is write protected. This is useful for checking
 * the write protection of directories on a network. The third
 * time the Is function is called, the function checks if Windows
 * is installed on a network server or if it is installed on the
 * local system.
 *
 * Note: Before running this script, set the defined constants
 *       so that they point to an existing file on the target
 *       system.
 *
 \*-----*/

#define EXAMPLE_DIR    "C:\\WINDOWS"
#define EXAMPLE_FILE  EXAMPLE_DIR^"Win.com"
#define TITLE         "Is Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_Is(HWND);

function ExFn_Is(hMSI)
    NUMBER nResult;
begin

    // Check if the EXAMPLE_FILE file is write-protected.
    nResult = Is (FILE_WRITEABLE, EXAMPLE_FILE);

```

```

// Report the results.
if (nResult = TRUE) then
    SprintfBox (INFORMATION, TITLE, "%s is writeable.", EXAMPLE_FILE);
elseif (nResult = FALSE) then
    SprintfBox (INFORMATION, TITLE, "%s is not writeable.", EXAMPLE_FILE);
else
    SprintfBox (INFORMATION, TITLE,
        "Unable to determine if %s is writeable.", EXAMPLE_FILE);
endif;

// Check if the directory is write-protected.
nResult = Is (DIR_WRITEABLE, EXAMPLE_DIR);

// Report the results.
if (nResult = TRUE) then
    SprintfBox (INFORMATION, TITLE, "%s is writeable.", EXAMPLE_DIR);
elseif (nResult = FALSE) then
    SprintfBox (INFORMATION, TITLE, "%s is not writeable.", EXAMPLE_DIR);
else
    SprintfBox (INFORMATION, TITLE,
        "Unable to determine if %s is writeable.", EXAMPLE_DIR);
endif;

// Check if Windows is being shared on a network.
nResult = Is (WINDOWS_SHARED, "");

// Report the results.
if (nResult = TRUE) then
    MessageBox ("Windows is shared.", INFORMATION);
elseif (nResult = FALSE) then
    MessageBox ("Windows is not shared.", INFORMATION);
else
    MessageBox ("Unable to determine if Windows is shared.", SEVERE);
endif;

end;

```

## ISCompareServicePack

The **ISCompareServicePack** function is supported only for compatibility with scripts created in InstallShield Professional. It is recommended that you determine the Windows service pack number by checking the value of `SYSINFO.WINNT.nServicePack` instead.

The **ISCompareServicePack** function compares the service pack number installed on a Windows system to the service pack number specified by `szServicePack`.

### Syntax

```
ISCompareServicePack ( szServicePack );
```

## Parameters

**Table 8** • ISCompareServicePack Parameters

| Parameter            | Description                                                                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szServicePack</b> | Specifies the Service Pack number to be compared with the Service Pack number on the target computer. This string must be in the format "Service Pack n", where n is the Service Pack number. The comparison is case sensitive. |

## Return Values

**Table 9** • ISCompareServicePack Return Values

| Return Value            | Description                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>LESS_THAN (1)</b>    | No Service Pack is installed or the Service Pack number on the target system is less than the value passed in szServicePack. |
| <b>EQUALS (2)</b>       | The Service Pack numbers match.                                                                                              |
| <b>GREATER_THAN (0)</b> | The Service Pack number on the target system is greater than the number passed in szServicePack.                             |
| <b>-1</b>               | ISCompareServicePack failed to compare the Service Pack numbers.                                                             |

## ISCompareServicePack Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the ISCompareServicePack function.
 *
 * Note: ISCompareServicePack is defined in Sdint.rul.
 *
 \*-----*/
#define SERVICE_PACK "Service Pack 3"

// Include Ifx.h for built-in InstallScript function prototypes.
```

```

#include "Ifx.h"

export prototype ExFn_ISCompareServicePack(HWND);

function ExFn_ISCompareServicePack(hMSI)
    BOOL bWinNT;
    NUMBER nvResult;
    STRING svResult;
begin

    // Determine which operating system is running.
    GetSystemInfo (OS, nvResult, svResult);

    if (nvResult = IS_WINDOWSNT) then
        // Running Windows NT.
        bWinNT = TRUE;

        // Check if Service Pack 3 is installed.
        nvResult = ISCompareServicePack (SERVICE_PACK);

        if (nvResult < 0) then
            MessageBox ("Error: ISCompareServicePack failed.", SEVERE);
        elseif (nvResult = LESS_THAN) then
            MessageBox ("No service pack or the service pack is less than "
                + SERVICE_PACK, INFORMATION);
        elseif (nvResult = EQUALS) then
            MessageBox ("The service pack is " + SERVICE_PACK, INFORMATION);
        elseif (nvResult = GREATER_THAN) then
            MessageBox ("The service pack is greater than "
                + SERVICE_PACK, INFORMATION);
        endif;
    else
        MessageBox ("The target system is not running Windows NT.", SEVERE);
    endif;

end;

```

## ISDeterminePlatform

The **ISDeterminePlatform** function sets the system variable **SYSINFO**, a structured variable whose members are used to specify information about the operating platform of the target computer. ISDeterminePlatform is called directly by the setup engine during setup initialization.

### Parameters

None

### Return Values

None

# IsEmpty

The **IsEmpty** function checks whether a variable of type VARIANT has been initialized.

To check whether a variable of type OBJECT has been assigned a reference to a valid object, call **IsObject**.

## Syntax

```
IsEmpty ( vVariant );
```

## Parameters

**Table 10** ▪ IsEmpty Parameters

| Parameter       | Description                           |
|-----------------|---------------------------------------|
| <b>vVariant</b> | Specifies the variable to be checked. |

## Return Values

**Table 11** ▪ IsEmpty Return Values

| Return Value     | Description                        |
|------------------|------------------------------------|
| <b>TRUE (1)</b>  | vVariant has been initialized.     |
| <b>FALSE (0)</b> | vVariant has not been initialized. |

## IsEmpty Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the IsEmpty function.
 *
 \*-----*/

function OnBegin()
    VARIANT vVariant;
    BOOL bEmpty;
    STRING szString;
begin
    bEmpty = IsEmpty ( vVariant );
    /* The message "vVariant is empty." is displayed. */
    if bEmpty then
        MessageBox ( "vVariant is empty." , INFORMATION );
    else
        MessageBox ( "vVariant is not empty." , INFORMATION );
    endif;

    /* Initialize vVariant. */
```

```

vVariant = szString;

bEmpty = IsEmpty ( vVariant );
/* The message "vVariant is not empty." is displayed. */
if bEmpty then
    MessageBox ( "vVariant is empty." , INFORMATION );
else
    MessageBox ( "vVariant is not empty." , INFORMATION );
endif;

/* Terminate example setup script. */
abort;
end;

```

## IsObject

The **IsObject** function checks whether a variable of type OBJECT has been assigned a reference to a valid object, using the [CreateObject](#) or [GetObject](#) functions.

### Syntax

```
IsObject ( oObject );
```

### Parameters

**Table 12** • IsObject Parameters

| Parameter      | Description                           |
|----------------|---------------------------------------|
| <b>oObject</b> | Specifies the variable to be checked. |

### Return Values

**Table 13** • IsObject Return Values

| Return Value | Description                                                  |
|--------------|--------------------------------------------------------------|
| <b>TRUE</b>  | oObject has been assigned a reference to a valid object.     |
| <b>FALSE</b> | oObject has not been assigned a reference to a valid object. |

## LaunchApp

The **LaunchApp** function enables you to launch another application from within the script. **LaunchApp** calls `LaunchAppAndWait( szCommand, szCmdLine, LAAW_OPTION_NOWAIT )`. For information on **LaunchApp** parameters and return values, see [LaunchAppAndWait](#).

## LaunchApp Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the LaunchApp function.
*
* LaunchApp is called to execute an application.
*
* Note: Before running this script, set the preprocessor
*       constants so that they reference the fully qualified
*       names of the Windows Notepad executable and a valid
*       text file on the target system.
*
\*-----*/

#define APPLICATION WINDIR^"Notepad.exe"
#define CMD_LINE    WINDIR^"Readme.txt"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_LaunchApp(HWND);

function ExFn_LaunchApp(hMSI)
begin
    // Launch the Windows Notepad application to edit
    // the Windows Readme.txt file.
    if (LaunchApp (APPLICATION, CMD_LINE) < 0) then
        MessageBox ("Unable to launch "+APPLICATION+".", SEVERE);
    endif;

end;
```

## LaunchAppAndWait

The **LaunchAppAndWait** function enables you to launch another application from within the script.

**LaunchAppAndWait** calls the following:

```
LaunchApplication( szProgram, szCmdLine, "", LAAW_STARTUPINFO.wShowWindow, LAAW_PARAMETERS.nTimeOut,
nOptions | LAAW_OPTION_CHANGEDIRECTORY | LAAW_OPTION_FIXUP_PROGRAM );
```

For more information on parameters and return values for **LaunchAppAndWait**, see [LaunchApplication](#).

### Syntax

```
LaunchAppAndWait ( szProgram, szCmdLine, nOptions );
```

## LaunchAppAndWait Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the LaunchAppAndWait function.
*
* This script presents the user with three options:
*
* -- Launch Notepad; after it closes, continue setup
* -- Launch Notepad and continue setup immediately
* -- Exit installation
*
* If the user selects the first option, the installation
* launches Notepad and then waits for it to close before
* continuing. If the user selects the second option, the
* installation launches Notepad and then continues immediately
* to execute the script. If the user selects the third option,
* the installation exits.
*
\*-----*/

#define PROGRAM          WINDIR^"Notepad.EXE"
#define LAUNCH_WAIT_TEXT "Launch Notepad; after it closes, continue setup"
#define LAUNCH_GO_TEXT   "Launch Notepad and continue setup immediately"
#define EXIT_TEXT        "Exit installation"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_LaunchAppAndWait(HWND);

function ExFn_LaunchAppAndWait(hMSI)
    STRING szProgram, szCmdLine, szMsg;
    BOOL bLaunchAndGo, bLaunchAndWait, bExit;
    NUMBER nWait;
begin

    // Run the installation in a normal window;
    Enable (BACKGROUND);
    Enable (DEFWINDOWMODE);

    // Disable the Back button in installation dialogs.
    Disable (BACKBUTTON);

    // Get an option from the user.
    AskOptions (EXCLUSIVE, "Test",
                LAUNCH_WAIT_TEXT, bLaunchAndWait,
                LAUNCH_GO_TEXT, bLaunchAndGo,
                EXIT_TEXT, bExit);
```

```

if !bExit then

    // Set variable to pass to LaunchAppAndWait
    // to indicate whether or not to wait.
    if bLaunchAndWait then
        nWait = WAIT;
    else
        nWait = NOWAIT;
    endif;

    // Launch Notepad; the value of nWait determines
    // when execution of the installation continues.
    if (LaunchAppAndWait (PROGRAM, "", nWait) < 0) then
        MessageBox ("Unable to launch "+ PROGRAM +".",SEVERE);
    endif;

    MessageBox ("Setup will now exit.", INFORMATION);

endif;

end;

```

## LaunchAppAndWaitInitStartupInfo

The **LaunchAppAndWaitInitStartupInfo** function initializes the [LAAW\\_STARTUPINFO](#) and [LAAW\\_PARAMETERS](#) system variables to the appropriate default values. This function is called automatically during installation initialization.

### Syntax

```
LaunchAppAndWaitInitStartupInfo ( );
```

## System Variables

**Table 14** ▪ LaunchAppAndWaitInitStartupInfo System Variables

| System Variable                            | Default Value            |
|--------------------------------------------|--------------------------|
| <b>LAAW_STARTUPINFO.cb</b>                 | SizeOf(LAAW_STARTUPINFO) |
| <b>LAAW_STARTUPINFO.lpReserved</b>         | NULL                     |
| <b>LAAW_STARTUPINFO.lpDesktop</b>          | NULL                     |
| <b>LAAW_STARTUPINFO.lpTitle</b>            | NULL                     |
| <b>LAAW_STARTUPINFO.wShowWindow</b>        | SW_SHOWDEFAULT           |
| <b>LAAW_STARTUPINFO.lpReserved2</b>        | NULL                     |
| <b>LAAW_STARTUPINFO.cbReserved2</b>        | 0                        |
| <b>LAAW_STARTUPINFO.dwFlags</b>            | STARTF_USESHOWWINDOW     |
| <b>LAAW_PARAMETERS.szStatusText</b>        | ""                       |
| <b>LAAW_PARAMETERS.szCommandLineResult</b> | ""                       |
| <b>LAAW_PARAMETERS.lpProcessAttributes</b> | NULL                     |
| <b>LAAW_PARAMETERS.lpThreadAttributes</b>  | NULL                     |
| <b>LAAW_PARAMETERS.bInheritHandles</b>     | FALSE                    |
| <b>LAAW_PARAMETERS.dwCreationFlags</b>     | NORMAL_PRIORITY_CLASS    |
| <b>LAAW_PARAMETERS.lpEnvironment</b>       | NULL                     |
| <b>LAAW_PARAMETERS.lpCurrentDirectory</b>  | NULL                     |
| <b>LAAW_PARAMETERS.nCallbackInterval</b>   | 1000                     |
| <b>LAAW_PARAMETERS.nLaunchResult</b>       | 0                        |

## Parameters

None.

## Return Values

**Table 15** ▪ LaunchAppAndWaitInitStartupInfo Return Values

| Return Value  | Description                                 |
|---------------|---------------------------------------------|
| ISERR_SUCCESS | This function always returns ISERR_SUCCESS. |

## LaunchApplication

The **LaunchApplication** function launches and optionally waits for the specified application.

**LaunchApplication** uses either the Windows API function [CreateProcess](#) or the Windows API function [ShellExecuteEx](#) (if `nOptions` includes `LAAW_OPTION_USE_SHELLEXECUTE`) to launch the specified application. After the application is launched, if the `LAAW_OPTION_WAIT` or `LAAW_OPTION_WAIT_INCL_CHILD` options are specified, the installation calls [WaitForApplication](#) to wait for the application to terminate; once the process has completed or the specified timeout value has elapsed, the installation continues.

### Syntax

```
LaunchApplication( byval string szProgram, byval string szCmdLine, byval string szDirectory, byval
    number nShowWindow, byval number nTimeOut, byval number nOptions );
```

## Parameters

**Table 16** ▪ LaunchApplication Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szProgram</b>   | <p>Specifies the complete path and file name of the application to be launched.</p> <p>If <code>nOptions</code> does not include <code>LAAW_OPTION_USE_SHELLEXECUTE</code>, you can instead specify the file name of the application to be launched in the <code>szCmdLine</code> parameter; if you do so, pass an empty string ("" ) in the <code>szProgram</code> parameter.</p> <p>The <code>szProgram</code> parameter supports URLs only if the <code>LAAW_OPTION_USE_SHELLEXECUTE</code> option is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>szCmdLine</b>   | <p>Specifies the command-line parameters to pass to the launched application. To launch the application with no command-line parameters, pass a null string ("" ).</p> <p>If <code>nOptions</code> does not include <code>LAAW_OPTION_USE_SHELLEXECUTE</code>, you can also specify the file name of the application to be launched in the <code>szCmdLine</code> parameter; if you do so, be sure to do the following:</p> <ul style="list-style-type: none"> <li>• Separate the path to the application and the command line with a single space.</li> <li>• If the fully qualified name of the application includes long folder names and/or a long file name, pass it to <a href="#">LongPathToQuote</a> before adding it to <code>szCmdLine</code>. For example:</li> </ul> <pre>szApplicationPath = WINDIR ^ "Notepad.exe"; szApplicationCmdLine = SRCDIR ^ "Readme.txt"; LongPathToQuote( szApplicationPath, TRUE ); szCmdLine = szApplicationPath + " " + szApplicationCmdLine;</pre> |
| <b>szDirectory</b> | <p>Specifies the working directory for the application. Note that if an empty string ("" ) is specified (and <code>LAAW_OPTION_USE_SHELLEXECUTE</code> is not specified), the function passes <code>NULL</code> to <b>CreateProcess</b> instead of an empty string.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 16** ▪ LaunchApplication Parameters (cont.)

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nShowWindow</b> | <p>Specifies the initial window state of the application as passed to <b>CreateProcess</b> in the wShowWindow parameter of the STARTUPINFO structure, or passed to <b>ShellExecuteEx</b> in the nShow parameter of the SHELLEXECUTEINFO structure (if LAAW_OPTION_USE_SHELLEXECUTE is specified). You can specify any documented value for the aforementioned functions; some values are predefined in ISRTWindows.h:</p> <ul style="list-style-type: none"> <li>• SW_FORCEMINIMIZE</li> <li>• SW_HIDE</li> <li>• SW_MAX</li> <li>• SW_MAXIMIZE</li> <li>• SW_MINIMIZE</li> <li>• SW_NORMAL</li> <li>• SW_RESTORE</li> <li>• SW_SHOW</li> <li>• SW_SHOWDEFAULT</li> <li>• SW_SHOWMAXIMIZED</li> <li>• SW_SHOWMINIMIZED</li> <li>• SW_SHOWMINNOACTIVE</li> <li>• SW_SHOWNA</li> <li>• SW_SHOWNOACTIVATE</li> <li>• SW_SHOWNORMAL</li> </ul> |
| <b>nTimeout</b>    | <p>Specifies the nTimeout value (in milliseconds) passed to the <b>WaitForApplication</b> function. Note that if you do not specify LAAW_OPTION_WAIT, the specified value is ignored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Table 16** ▪ LaunchApplication Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOptions</b> | <p>Specifies various options, including whether the installation should wait for the launched application to terminate before continuing.</p> <p>Pass one of the following predefined constants in this parameter. You can combine these constants by using the bitwise OR operator (   ), with the following exceptions: you cannot combine LAAW_OPTION_NOWAIT with LAAW_OPTION_WAIT, and you cannot combine LAAW_OPTION_HIDDEN, LAAW_OPTION_MINIMIZED, and LAAW_OPTION_MAXIMIZED.</p> <ul style="list-style-type: none"> <li>• <b>LAAW_OPTION_USE_SHELLEXECUTE</b>—Indicates that the function should call the Windows API function <b>ShellExecuteEx</b> instead of calling <b>CreateProcess</b> to launch the application.</li> <li>• <b>LAAW_OPTION_NOWAIT</b>—Passed through the function to <b>WaitForApplication</b>. Note that using this parameter is equivalent to calling the function <b>LaunchApp</b>.</li> <li>• <b>LAAW_OPTION_WAIT</b>—Passed through the function to <b>WaitForApplication</b>.</li> <li>• <b>LAAW_OPTION_USE_CALLBACK</b>—Passed through the function to <b>WaitForApplication</b>.</li> <li>• <b>LAAW_OPTION_SET_BATCH_INSTALL</b>—Specifies that the function internally sets BATCH_INSTALL to a non-zero value if it detects that the launched application causes a change that requires a reboot, such as updating the RunOnce key. The function attempts to determine this by checking the state of the system before launching the specified application and then comparing the current system state after launching the application (and waiting for the application to complete if LAAW_OPTION_WAIT is specified.) This flag can be used when launching third-party installations that do not return status information indicating that a reboot is needed.</li> </ul> <p>LAAW_OPTION_SET_BATCH_INSTALL is available for InstallScript event-driven code in InstallScript and InstallScript MSI projects. It does not have any effect in InstallScript custom actions.</p> <ul style="list-style-type: none"> <li>• <b>LAAW_OPTION_SHOW_HOURLASS</b>—Specifies that the cursor changes to an hourglass while the launched application is running.</li> <li>• <b>LAAW_OPTION_WAIT_INCL_CHILD</b>—Passed through the function to <b>WaitForApplication</b>.</li> </ul> |

**Table 16** ▪ LaunchApplication Parameters (cont.)

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOptions (cont.)</b> | <div>  </div> <p><b>Note</b> ▪ When <code>LAAW_OPTION_WAIT_INCL_CHILD</code> is used, the function detects and waits for only direct child processes of the launched process—not for any additional child processes that are launched by child processes of the initially launched process.</p> <p>For details about using <code>LAAW_OPTION_USE_SHELLEXECUTE</code> with <code>LAAW_OPTION_WAIT_INCL_CHILD</code>, see the <a href="#">Additional Information</a>.</p> <p>This parameter also supports the following options, but they are no longer recommended:</p> <ul style="list-style-type: none"> <li>• <b>LAAW_OPTION_HIDDEN</b>—Specifies that the launched application's main window is initially hidden.</li> <li>• <b>LAAW_OPTION_MINIMIZED</b>—Specifies that the launched application's main window is initially minimized.</li> <li>• <b>LAAW_OPTION_MAXIMIZED</b>—Specifies that the launched application's main window is initially maximized.</li> <li>• <b>LAAW_OPTION_NO_CHANGEDIRECTORY</b>—This is obsolete. This parameter is ignored.</li> <li>• <b>LAAW_OPTION_CHANGEDIRECTORY</b>—Specifies that <b>LaunchApplication</b> should temporarily update the current directory of the installation to that of the application about to be launched. By default, <b>LaunchApplication</b> does not modify the current directory of the installation. Note that <b>LaunchApplication</b> resets the current directory of the installation back to the original value before <b>LaunchApplication</b> returns.</li> </ul> <div>  </div> <p><b>Note</b> ▪ Calling <b>LaunchAppAndWait</b> instead of <b>LaunchApplication</b> automatically includes this option.</p> <ul style="list-style-type: none"> <li>• <b>LAAW_OPTION_FIXUP_PROGRAM</b> —Specifies that <b>LaunchApplication</b> should call <code>LongPathFromShortPath</code> on <code>szProgram</code> in order to ensure that the call to <b>CreateProcess</b> or <b>ShellExecuteEx</b> works correctly. In most cases, this should not be needed.</li> </ul> <div>  </div> <p><b>Note</b> ▪ Calling <b>LaunchAppAndWait</b> instead of <b>LaunchApplication</b> automatically includes this option.</p> |

## Return Values

**Table 17** ▪ LaunchApplication Return Values

| Return Value              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the application was launched successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the application was not launched successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                           |  <p><b>Note</b> ▪ If the application cannot be launched, the LAAW_PARAMETERS system variable's nLaunchResult member contains the result of calling the Windows API function <b>GetLastError</b> after the <b>CreateProcess</b> or <b>ShellExecuteEx</b> call. If the function is successful and the LAAW_OPTION_WAIT option was specified, the LAAW_PARAMETERS system variable's nLaunchResult member contains the return code of the launched application.</p> |

## Additional Information

- If you are not using LAAW\_OPTION\_USE\_SHELLEXECUTE, update the LAAW\_STARTUPINFO system variable before calling **LaunchApplication** to customize the behavior of the application.

If you are using LAAW\_OPTION\_USE\_SHELLEXECUTE, customize the LAAW\_SHELLEXECUTEINFO structure to customize the behavior of the application.

If you are using LAAW\_OPTION\_USE\_SHELLEXECUTE on systems running Windows Vista or later and you want to launch the application using the full administrator account (similar to right-clicking the executable file to be run and clicking Run as Administrator), set LAAW\_SHELLEXECUTEVERB to **runas** before using **LaunchApplication** in your script:

```
LAAW_SHELLEXECUTEVERB = "runas";
```

This ensures that the application is always run with full administrator privileges regardless of whether the application to be launched has an application manifest with relevant settings. Note that this may trigger a User Account Control (UAC) prompt for consent or credentials.

On systems running operating systems earlier than Windows Vista, if **runas** is used, a Run As dialog box is displayed. The behavior is similar to right-clicking the executable file to be run and clicking Run As. This dialog box enables the end user to select the user account that should be used to run the application.

- To obtain identification information about the launched process, use the LAAW\_PROCESS\_INFORMATION system variable or the LAAW\_SHELLEXECUTEINFO system variable (if you are using LAAW\_OPTION\_USE\_SHELLEXECUTE).
- Note that if you are using LAAW\_OPTION\_USE\_SHELLEXECUTE, the LAAW\_PROCESS\_INFORMATION is not used, except for the hProcess member. The hProcess member is updated to the process handle of the launched process (from the LAAW\_SHELLEXECUTEINFO.hProcess member).
- **ShellExecuteEx** does not return the process ID of the launched process. Thus, if LAAW\_OPTION\_USE\_SHELLEXECUTE is used, the LAAW\_OPTION\_WAIT\_INCL\_CHILD option works only if the

Windows API **GetProcessId** is available so that the function can determine the process ID. According to the Windows API documentation, **GetProcessId** is available on Windows XP SP1 and later and Windows Server 2003 and later. If this API is not available, `LAAW_OPTION_WAIT_INCL_CHILD` behaves as `LAAW_OPTION_WAIT`.

- When the installation is run from any removable media, such as a CD or a DVD, the `Setup.exe` file on Disk1 may not be available during the entire installation. (If `Setup.exe` becomes unavailable while it is running, the operating system sometimes displays a prompt to request that the end user insert the correct disk, and this may cause the installation to fail.) Therefore, to avoid this problem, the `Setup.exe` file is copied to a Temp folder, and the installation is relaunched from there. The original `Setup.exe` then terminates. However, when this happens, **LaunchApplication** behaves as if the installation has completed, and it does not wait.

To avoid this issue, you may want to use the `/clone_wait` parameter when you are launching the child installation; when this occurs, the launched installation keeps the original launched process running, and the parent installation then waits. Note, however, that this may cause problems if the original CD containing `Setup.exe` is not available throughout the entire installation. This includes multiple-CD installations, where the first CD is not available during some parts of the installation.

The only other way to avoid this problem is to add code that determines the ID of the child processes of the launched process and wait for the child process to complete.

## LaunchApplicationInit

The **LaunchApplicationInit** function initializes the `LAAW_STARTUPINFO` and `LAAW_PARAMETERS` system variables to the appropriate default values. This function is called automatically during installation initialization. This function supersedes the `LaunchAppAndWaitInitStartupInfo` function.

### Syntax

```
LaunchApplicationInit( );
```

## System Variables

**Table 18** ▪ LaunchApplicationInit System Variables

| System Variable                              | Default Value                                    |
|----------------------------------------------|--------------------------------------------------|
| <b>LAAW_PARAMETERS.bCallbackEndedWait</b>    | FALSE                                            |
| <b>LAAW_PARAMETERS.bInheritHandles</b>       | FALSE                                            |

| <b>LAAW_STARTUPINFO.lpReserved</b>        | NULL                            |
| <b>LAAW_STARTUPINFO.lpReserved2</b>       | NULL                            |
| <b>LAAW_STARTUPINFO.lpTitle</b>           | NULL                            |
| <b>LAAW_STARTUPINFO.wShowWindow</b>       | SW_SHOWDEFAULT                  |

## Parameters

None.

## Return Values

**Table 19** ▪ LaunchApplicationInit Return Values

| Return Value  | Description                                 |
|---------------|---------------------------------------------|
| ISERR_SUCCESS | This function always returns ISERR_SUCCESS. |

## ListAddItem

The **ListAddItem** function adds a numeric element to a number list before or after the current element.

**Note** ▪ *ListAddItem works only with numbered lists.*

### Task

#### To traverse a list:

1. Call [ListGetFirstItem](#) to get the first element in the list.
2. Call [ListGetNextItem](#) repeatedly until you reach the end of the list.

To make a specific element in the list the current element, call [ListSetIndex](#).

## Syntax

```
ListAddItem ( listID, nItem, nPlacementFlag );
```

## Parameters

**Table 20** ▪ ListAddItem Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>         | Specifies the name of a number list. The list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> .                                                                                                                                                                                                                                                                        |
| <b>nItem</b>          | Specifies the numeric element to add to the list.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>nPlacementFlag</b> | Specifies where to put nItem relative to the current element. The new element will go either before or after the current element. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>AFTER</b>—Adds the new element after the current element in the list.</li> <li>● <b>BEFORE</b>—Adds the new element before the current element in the list.</li> </ul> |

## Return Values

**Table 21** ▪ ListAddItem Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt; = ISERR_SUCCESS (0)</b>     | The function was successful.                                                                                                               |
| <b>&lt; ISERR_SUCCESS (0)</b>       | The function was not successful.                                                                                                           |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListAddItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListAddItem function.
*
* First, an empty list is created by a call to ListCreate.
* Then ListAddItem is called three times to add the numbers
* 1, 3, and 2 to the list. Although the numbers are not added
* in ascending order, they are arranged in that order in the
* list by means of the placement flag that is passed in the
* third parameter of each call to ListAddItem. After the list
* has been built, it is displayed. Finally the current element
```

```

* is displayed.
*
\*-----*/

#define TITLE "ListAddItem Example"
#define MSSG  "The following is a list of the items added:\n\n"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListAddItem(HWND);

function ExFn_ListAddItem(hMSI)
    NUMBER nvItem, nvResult;
    LIST  listID;
    STRING szMsg, svItem;
begin

    // Create an empty number list.
    listID = ListCreate (NUMBERLIST);

    //If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add the number 1 to the list.
    if (ListAddItem (listID, 1, AFTER) < 0) then
        MessageBox ("First call to ListAddItem failed.", INFORMATION);
        abort;
    endif;

    // The integer 1, in position 1, is the current element.
    // Add the number 3 after the current element.
    if (ListAddItem (listID, 3, AFTER) < 0) then
        MessageBox ("Second call to ListAddItem failed.", INFORMATION);
        abort;
    endif;

    // The integer 3, in position 2, is the current element.
    // Add the number 2 to the list before the current element.
    if (ListAddItem (listID, 2, BEFORE) < 0) then
        MessageBox ("Third call to ListAddItem failed.", INFORMATION);
        abort;
    endif;

    // Retrieve and display the current element.
    ListCurrentItem (listID, nvItem);

    sprintfBox (INFORMATION, TITLE, "Current Item: %d", nvItem);

    // Start building the message to report the numbers.
    szMsg = MSSG;

    // Get the numbers and add them to the message.

```

```

    nvResult = ListGetFirstItem (listID, nvItem);
    while (nvResult != END_OF_LIST)
        NumToStr (svItem, nvItem);
        szMsg = szMsg + svItem + " ";
        nvResult = ListGetNextItem (listID, nvItem);
    endwhile;

    // Display the numbers.
    MessageBox (szMsg, INFORMATION);

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## ListAddList

The **ListAddList** function adds elements from one list (listAdd) to the destination list (listDest). This function is available for both string lists and number lists; however, the types of listDest and listAdd must match.

### Syntax

```
ListAddList (listDest, listAdd, nPlacementFlag);
```

## Parameters

**Table 22** ▪ ListAddList Parameters

| Parameter             | Description                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listDest</b>       | Specify the destination list. <b>ListAddList</b> adds new elements either before or after the current element of this list.                                                                                        |
| <b>listAdd</b>        | Specify the list that contains the elements to be added to the destination list. <b>ListAddList</b> adds all elements (from the current element in this list to the last element in this list) to ListDest.        |
| <b>nPlacementFlag</b> | Specify whether <b>ListAddList</b> should add the list elements before or after the current element of listDest. Available values are: <ul style="list-style-type: none"> <li>• BEFORE</li> <li>• AFTER</li> </ul> |

## Return Values

**Table 23** ▪ ListAddList Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# ListAddString

The **ListAddString** function adds a string to a string list before or after the current element.

**Note** ▪ *ListAddString works only with string lists.*

### Task

#### To traverse a list:

1. Call **ListGetFirstItem** to get the first element in the list.
2. Call **ListGetNextItem** repeatedly until you reach the end of the list.

To make a specific element in the list the current element, call **ListSetIndex**.

## Syntax

```
ListAddString ( listID, szString, nPlacementFlag );
```

## Parameters

**Table 24** ▪ ListAddString Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>         | Specifies the name of a string list. The list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> .                                                                                                                                                                                                                                                                        |
| <b>szString</b>       | Specifies the string to add to the list.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>nPlacementFlag</b> | Specifies where to put szString relative to the current element. The new string will go either before or after the current element. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>AFTER</b>—Adds the new string after the current element in the list.</li> <li>● <b>BEFORE</b>—Adds the new string before the current element in the list.</li> </ul> |

## Return Values

**Table 25** ▪ ListAddString Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt; = ISERR_SUCCESS (0)</b>     | The function was successful.                                                                                                               |
| <b>&lt; ISERR_SUCCESS (0)</b>       | The function was not successful.                                                                                                           |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListAddString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListAddString function.
*
* ListAddString is called to add a string to the string list.
* Then it is called again to add another string after the
* first. This string is also set as the current element.
* ListAddString is called for the third time to add a string
* before the current element.
*
*-----*/

```

```

#define TITLE_TEXT "ListAddString Example"
#define MSG_TEXT   "Hardware devices:"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListAddString(HWND);

function ExFn_ListAddString(hMSI)
    STRING szString, svString;
    LIST listID;
begin

    // Create an empty string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add a string to the list. This string becomes the current element.
    szString = "Keyboard";
    if (ListAddString (listID, szString, AFTER) < 0) then
        MessageBox ("ListAddString failed.", INFORMATION);
    endif;

    // Add a second string; insert it after the current element.
    // This string then becomes the current element.
    szString = "Mouse";
    if (ListAddString (listID, szString, AFTER) < 0) then
        MessageBox ("ListAddString failed.", INFORMATION);
    endif;

    // Add a third string; insert it before the current element.
    szString = "Monitor";

    if (ListAddString (listID, szString, BEFORE) < 0) then
        MessageBox ("ListAddString failed.", INFORMATION);
    endif;

    // Show the list of strings.
    SdShowInfoList (TITLE_TEXT, MSG_TEXT, listID);

    // Retrieve and display the current element.
    ListCurrentString (listID, svString);

    MessageBox (svString, INFORMATION);

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

# ListAppendFromArray

**Project** ▪ This information applies to InstallScript projects.

The **ListAppendFromArray** function appends the elements in the array that is specified by `varSource` to the list that is specified by `listResult`.

## Syntax

```
ListAppendFromArray ( listResult, varSource, bString );
```

## Parameters

**Table 26** ▪ ListAppendFromArray Parameters

| Parameter         | Description                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listResult</b> | Specifies the name of a list. The list identified by <code>listResult</code> must already have been initialized by a call to <a href="#">ListCreate</a> .                                                                                  |
| <b>varSource</b>  | Specifies the array to append to the list.                                                                                                                                                                                                 |
| <b>bString</b>    | Set this parameter to TRUE if <code>varSource</code> is a string array and <code>listResult</code> is a string list; set this parameter to FALSE if <code>varSource</code> is a number array and <code>listResult</code> is a number list. |

## Return Values

**Table 27** ▪ ListAppendFromArray Return Values

| Return Value              | Description                                                             |
|---------------------------|-------------------------------------------------------------------------|
| <b>&gt;= 0</b>            | The new number of elements in the list.                                 |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was unable to append the array to the list. |

## Comments

The array and list types must match (that is, both be string or both be numeric) or the function will fail. If necessary, convert the data appropriately by calling `ListConvertNumToStr` or `ListConvertStrToNum` before calling `ListAppendToArray`.

# ListAppendToArray

**Project** ▪ This information applies to InstallScript projects.

The **ListAppendToArray** function appends the elements in the list that is specified by listSource to the array that is specified by varResult, resizing the array appropriately to store the new elements.

## Syntax

```
ListAppendToArray ( varResult, listSource, bString );
```

## Parameters

**Table 28** ▪ ListAppendToArray Parameters

| Parameter         | Description                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>varResult</b>  | Specifies an array.                                                                                                                                                                    |
| <b>listSource</b> | Specifies the list to append to the array. The list identified by listSource must already have been initialized by a call to <a href="#">ListCreate</a> .                              |
| <b>bString</b>    | Set this parameter to TRUE if varResult is a string array and listSource is a string list; set this parameter to FALSE if varResult is a number array and listSource is a number list. |

## Return Values

**Table 29** ▪ ListAppendToArray Return Values

| Return Value              | Description                                                             |
|---------------------------|-------------------------------------------------------------------------|
| <b>&gt;= 0</b>            | The new number of elements in the array.                                |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was unable to append the list to the array. |

## Comments

The array and list types must match (that is, both be string or both be numeric) or the function will fail. If necessary, convert the data appropriately by calling ListConvertNumToStr or ListConvertStrToNum before calling ListAppendToArray.

The current size of the array determines where the end of the array is and thus where the new elements are placed. For example, if the size of the array is 10 but only one element contains a string, the new data is still added as the 11th and later elements. If you use an autosized array the new elements are added to the end of the array.

# ListConvertNumToStr

**Project** ▪ This information applies to InstallScript projects.

The **ListConvertNumToStr** function converts each numeric element in listNumber to its string equivalent and appends it to listString.

## Syntax

```
ListConvertNumToStr (listString, listNumber);
```

## Parameters

**Table 30** ▪ ListConvertNumToStr Parameters

| Parameter         | Description                                                                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listString</b> | Specifies the string list to which to append the converted numbers. The list identified by listString must already have been initialized by a call to <a href="#">ListCreate</a> . |
| <b>listNumber</b> | Specifies a number list. The list identified by listNumber must already have been initialized by a call to <b>ListCreate</b> .                                                     |

## Return Values

**Table 31** ▪ ListConvertNumToStr Return Values

| Return Value               | Description                                                                          |
|----------------------------|--------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully converted the number list to a string list. |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to convert the number list to a string list.  |

## Comments

The function uses [NumToStr](#) to convert the numeric elements to strings; if the conversion fails for an element in listNumber, a null string ("") is appended to listString for that element.

# ListConvertStrToNum

**Project** ▪ This information applies to InstallScript projects.

The **ListConvertStrToNum** function converts each string element in listString to its numeric equivalent and appends it to listNumber.

## Syntax

```
ListConvertStrToNum (listNumber, listString );
```

## Parameters

**Table 32** ▪ ListConvertStrToNum Parameters

| Parameter         | Description                                                                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listNumber</b> | Specifies the number list to which to append the converted strings. The list identified by listNumber must already have been initialized by a call to <a href="#">ListCreate</a> . |
| <b>listString</b> | Specifies a string list. The list identified by listString must already have been initialized by a call to <a href="#">ListCreate</a> .                                            |

## Return Values

**Table 33** ▪ ListConvertStrToNum Return Values

| Return Value               | Description                                                                          |
|----------------------------|--------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully converted the string list to a number list. |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to convert the string list to a number list.  |

## Comments

The function uses [StrToNum](#) to convert the strings to numbers; if the conversion fails for an element in listString, 0 is appended to listNumber for that element.

# ListCount

The **ListCount** function returns the number of elements in a list.

**Note** ▪ This function works with both strings and number lists.

## Syntax

```
ListCount ( listID );
```

## Parameters

**Table 34** ▪ ListCount Parameters

| Parameter     | Description                                    |
|---------------|------------------------------------------------|
| <b>listID</b> | Specifies the name of a string or number list. |

## Return Values

**Table 35** ▪ ListCount Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= 0</b>                      | The number of items in the list.                                                                                                           |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |
| <b>&lt; 0</b>                       | ListCount was unable to determine the number of elements in the list.                                                                      |

## ListCount Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListCount function.
*
* The following adds the names of the program folders to a
* string list and then displays the number of strings in
* the list.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListCount(HWND);

function ExFn_ListCount(hMSI)
    STRING svString;
    LIST listID;
    NUMBER nCount;
begin
```

```

// Create a string list.
listID = ListCreate (STRINGLIST);

// If an error occurred, report it; then terminate.
if (listID = LIST_NULL) then
    MessageBox ("Unable to create list.", SEVERE);
    abort;
endif;

// Get the names of the program folders into a list.
GetGroupNameList (listID);

// Count the number of program folders in the list.
nCount = ListCount (listID);

// Report error or display the folder count.
if (nCount < 0) then
    MessageBox ("ListCount failed.", SEVERE);
else
    sprintfBox (INFORMATION, "ListCount",
                "There are %i program folders.", nCount);
endif;

// Remove the list from memory.
ListDestroy (listID);

end;

```

## ListCreate

The **ListCreate** function creates an empty string or number list. You can create any number of lists in a script. A list may contain any number of elements. The only constraint is the amount of available free memory.

When calling any of the list functions, you must pass a valid ID of the list returned by this function. Verify this function was successful in creating the list. Otherwise, all the list functions will fail on the invalid list.

When you no longer need the list, you can destroy the list with the [ListDestroy](#) function.

Each list has a pointer that identifies an element as the “current” element of the list. The various list functions reposition the current element of the list.

---

**Note** • A list cannot contain both types of elements—numbers and strings. InstallScript provides separate functions to work with string lists and with number lists. You cannot use the ID of a number list with the string list functions and vice versa. Use list functions that end in “Item” for number lists and use list functions that end in “String” for string lists.

### Syntax

```
ListCreate ( nListType );
```

## Parameters

**Table 36** ▪ ListCreate Parameters

| Parameter        | Description                                                                                                                                                                                                                                                  |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nListType</b> | Specifies the type of list to create. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>NUMBERLIST</b>—Specifies a number list.</li> <li>● <b>STRINGLIST</b>—Specifies a string list.</li> </ul> |

## Return Values

**Table 37** ▪ ListCreate Return Values

| Return Value          | Description                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ListID</b>         | The ID of the newly created, empty list. You must use this ID whenever you want to use this list in other InstallScript list functions. You must check this variable and be sure the function did not return LIST_NULL.       |
| <b>LIST_NULL (-1)</b> | Indicates that InstallShield is unable to create a list. This is a seldom seen condition that is the result of a serious memory problem. You might experience difficulties in continuing the setup with such memory problems. |

## Additional Information

Before you can pass a valid list ID to any function that requires a list, you must build the list using ListCreate.

## ListCreate Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListCreate and ListDestroy functions.
*
* ListCreate is called to create a numbered list. ListDestroy
* is called to destroy it.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"
```

```

export prototype ExFn_ListCreate(HWND);

function ExFn_ListCreate(hMSI)
    LIST listID;
    NUMBER nvItem;
begin

    // Create an empty number list.
    listID = ListCreate (NUMBERLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add the number 1078 to the list.
    ListAddItem (listID, 1078, AFTER);

    // Add the number 304 to the list
    ListAddItem (listID, 304, AFTER);

    // Retrieve the current item in the list (304).
    ListCurrentItem (listID, nvItem);

    // Display the current item.
    sprintfBox (INFORMATION, "ListCreate",
        "Current item in list: %d", nvItem);

    // Retrieve the first item in the list (1078).
    ListGetFirstItem (listID, nvItem);

    // Display the first item.
    sprintfBox (INFORMATION, "ListCreate",
        "First item in list: %d", nvItem);

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## ListCurrentItem

The **ListCurrentItem** function retrieves the current element from the number list specified in listID.

You can also use the [ListGetFirstItem](#) and [ListGetNextItem](#) functions to traverse the list and make any element the current element.

---

**Note** • *ListCurrentItem works only with numbered lists.*

### Syntax

```
ListCurrentItem ( listID, nvItem );
```

## Parameters

**Table 38** ▪ ListCurrentItem Parameters

| Parameter     | Description                                           |
|---------------|-------------------------------------------------------|
| <b>listID</b> | Specifies a number list.                              |
| <b>nvItem</b> | Returns the value of the current element in the list. |

## Return Values

**Table 39** ▪ ListCurrentItem Return Values

| Return Value                 | Description                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                     | Indicates that the function successfully retrieved the current element in a number list.                                                   |
| <b>&lt; 0</b>                | Indicates that the function was unable to retrieve the current element in a number list.                                                   |
| <b>END_OF_LIST (1)</b>       | Indicates that the list is empty and therefore does not have a current element.                                                            |
| <b>ISERR_LIST_NOSUCHLIST</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListCurrentItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListCurrentItem function.
*
* This script adds three numbers to a list and then retrieves
* and displays the value of the current list item.
*
\*-----*/

#define TITLE_TEXT "ListCurrentItem Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListCurrentItem(HWND);
```

```

function ExFn_ListCurrentItem(hMSI)
    STRING szMsg;
    LIST listID;
    NUMBER nItem;
begin

    // Create the number list.
    listID = ListCreate (NUMBERLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add the numbers 100, 200, and 300 to the list.
    for nItem = 100 to 300 step 100
        ListAddItem (listID, nItem, AFTER);
    endfor;

    // Get the current element from the number list.
    if (ListCurrentItem (listID, nItem) < 0) then
        MessageBox ("ListCurrentItem failed.", SEVERE);
    else
        // Report the value of the current item.
        szMsg = "Value of current element in list: %d";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, nItem);
    endif;

end;

```

## ListCurrentString

The **ListCurrentString** function retrieves the current element from the string list specified in listID.

You can also use the [ListGetFirstString](#) and [ListGetNextString](#) functions to traverse the list and make any element the current element.

---

**Note** ▪ *ListCurrentString works only with string lists.*

### Syntax

```
ListCurrentString ( listID, svString );
```

## Parameters

**Table 40** ▪ ListCurrentString Parameters

| Parameter       | Description                                           |
|-----------------|-------------------------------------------------------|
| <b>listID</b>   | Specifies a string list.                              |
| <b>svString</b> | Returns the value of the current element in the list. |

## Return Values

**Table 41** ▪ ListCurrentString Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully retrieved the current element in a string list.                                                   |
| <b>&lt; 0</b>                       | Indicates that the function was unable to retrieve the current element in a string list.                                                   |
| <b>END_OF_LIST (1)</b>              | Indicates that the list is empty and therefore does not have a current element.                                                            |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListCurrentString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListCurrentString function.
*
* ListAddString retrieves the current string element from a
* string list.
*
\*-----*/

#define TITLE_TEXT "ListCurrentString Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListCurrentString(HWND);
```

```

function ExFn_ListCurrentString(hMSI)
    STRING szString, svString, szMsg;
    LIST listID;
begin

    // Create the string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add three strings to the list.
    ListAddString (listID, "First string", AFTER);
    ListAddString (listID, "Second string", AFTER);
    ListAddString (listID, "Third string", AFTER);

    // Get the current element in the string list.
    if (ListCurrentString (listID, svString) < 0) then
        MessageBox ("ListCurrentString failed.", SEVERE);
    else
        // Report the value of the current item.
        szMsg = "Current element in list: '%s'";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svString);
    endif;

end;

```

## ListDeleteAll

The **ListDeleteAll** function deletes all elements in the specified list. This function can be used for both string and number lists.

### Syntax

```
ListDeleteAll ( list);
```

## Parameters

**Table 42** ▪ ListDeleteAll Parameters

| Parameter   | Description                                      |
|-------------|--------------------------------------------------|
| <b>list</b> | The list specified to have all elements deleted. |

## Return Values

**Table 43** ▪ ListDeleteAll Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# ListDeleteItem

The **ListDeleteItem** function removes the current element from the number list you specify in listID.

You can also use the [ListGetFirstItem](#) and [ListGetNextItem](#) functions to traverse the list and make any element the current element.

**Note** ▪ *ListDeleteItem works only with numbered lists.*

## Syntax

```
ListDeleteItem ( listID );
```

## Parameters

**Table 44** ▪ ListDeleteItem Parameters

| Parameter     | Description                                                         |
|---------------|---------------------------------------------------------------------|
| <b>listID</b> | Specifies the number list from which to delete the current element. |

## Return Values

**Table 45** ▪ ListDeleteItem Return Values

| Return Value                 | Description                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                     | Indicates that the function successfully deleted the current element from a number list.                                                   |
| <b>&lt; 0</b>                | Indicates that the list is empty and therefore does not have a current element.                                                            |
| <b>END_OF_LIST (1)</b>       | Indicates that the list is empty and therefore does not have a current element.                                                            |
| <b>ISERR_LIST_NOSUCHLIST</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListDeleteItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListDeleteItem function.
*
* This script first creates a list of numbers and prompts the
* user for a number to delete. Then ListFindItem is called to
* make the selected number the current item. Next,
* ListDeleteItem is called to delete the selected number from
* the list. Finally, the numbers remaining in the list are
* displayed.
*
\*-----*/

#define TITLE_TEXT "ListDeleteItem Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

```

```

export prototype ExFn_ListDeleteItem(HWND);

function ExFn_ListDeleteItem(hMSI)
    STRING    svItem, szMsg;
    LIST      listID;
    NUMBER    nvItem, nvResult;
begin

    // Create the number list.
    listID = ListCreate (NUMBERLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add the numbers 1, 2, 3, and 4 to the list.
    for nvItem = 1 to 4
        ListAddItem (listID, nvItem, AFTER);
    endfor;

    repeat
        // Disable the Back button.
        Disable (BACKBUTTON);

        // Prompt user to select a number to delete.
        if AskText ("The numbers 1, 2, 3, and 4 have been added to a list.\n"+
            "Select one of those numbers to delete.", "", svItem)then
        endif;

        // Convert the value from string data to a number data.
        nvResult = StrToNum (nvItem, svItem);

        if (nvItem < 1) || (nvItem > 4) then
            MessageBox ("You must enter a number between 1 and 4.", WARNING);
        endif;
    until (nvItem > 0) && (nvItem < 5);

    // Make the first list element the current element
    // so ListFindItem will search from the top of the list.
    ListSetIndex (listID, 0);

    // Search for the selected number.
    nvResult = ListFindItem(listID, nvItem);

    // Delete the selected number from the list.
    if (ListDeleteItem (listID) < 0) then
        MessageBox ("Unable to delete selected number.", SEVERE);
    else
        // Start building the message to report the remaining numbers.
        szMsg = "The list now contains the following numbers:\n\n";

        // Get the remaining numbers and add them to the message.
        nvResult = ListGetFirstItem (listID, nvItem);
    endif;
endrepeat

```

```

while (nvResult != END_OF_LIST)
    NumToStr (svItem, nvItem);
    szMsg = szMsg + svItem + " ";
    nvResult = ListGetNextItem (listID, nvItem);
endwhile;

// Display the remaining numbers.
MessageBox (szMsg, INFORMATION);
endif;

// Remove the list from memory.
ListDestroy (listID);

end;

```

## ListDeleteString

The **ListDeleteString** function removes the current element from the string list you specify in listID.

You can also use the [ListGetFirstString](#) and [ListGetNextString](#) functions to traverse the list and make any element the current element.

---

**Note** ▪ *ListCurrentString works only with string lists.*

### Syntax

```
ListDeleteString ( listID );
```

## Parameters

**Table 46** ▪ ListDeleteString Parameters

| Parameter     | Description                                                         |
|---------------|---------------------------------------------------------------------|
| <b>listID</b> | Specifies the string list from which to delete the current element. |

## Return Values

**Table 47** ▪ ListDeleteString Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully deleted the current element from a string list.                                                   |
| <b>&lt; 0</b>                       | Indicates that the function was unable to delete the current element from a string list.                                                   |
| <b>END_OF_LIST (1)</b>              | Indicates that the list is empty and therefore does not have a current element.                                                            |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListDeleteString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListDeleteString function.
*
* This script first creates a list of strings and then displays
* the current string in a dialog. Next, ListDeleteString
* is called twice, deleting the last two strings in the list.
* The current string is then displayed again.
*
\*-----*/

#define TITLE_TEXT "ListDeleteString & ListCurrentString"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListDeleteString(HWND);
```

```

function ExFn_ListDeleteString(hMSI)
    STRING    szString, svString, szMsg;
    LIST      listID;
begin

    // Create the string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add three strings to the list.
    ListAddString (listID, "First string", AFTER);
    ListAddString (listID, "Second string", AFTER);
    ListAddString (listID, "Third string", AFTER);

    // Display the current string in the list.
    if (ListCurrentString (listID, svString) < 0) then
        MessageBox ("First call to ListCurrentString failed.", SEVERE);
    else

        szMsg  = "Current string in list: %s";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svString);

    endif;

    // Remove the current string ("Value three").
    if (ListDeleteString (listID) < 0) then
        MessageBox ("First call to ListDeleteString failed.", SEVERE);
    endif;

    // Remove the current string ("Value two").
    if (ListDeleteString (listID) < 0) then
        MessageBox ("Second call to ListDeleteString failed.", SEVERE);
    endif;

    // Display the current string in the list.
    if (ListCurrentString(listID, svString) < 0) then
        MessageBox ("Second call to ListCurrentString failed.", SEVERE);
    else
        szMsg  = "Current string in list: %s";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svString);
    endif;

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

# ListDestroy

The **ListDestroy** function destroys the contents of a list and the list itself. Use this function to remove the string or number list identified in listID.

You should destroy all the lists you create when you no longer need them or at the end of the setup script. When you destroy a list, you free all memory associated with the list.

**Note** ▪ This function works with both string and number lists. After you destroy a list, do not use that in any list function.

## Syntax

```
ListDestroy ( listID );
```

## Parameters

**Table 48** ▪ ListDestroy Parameters

| Parameter | Description                                     |
|-----------|-------------------------------------------------|
| listID    | Specifies the string or number list to destroy. |

## Return Values

**Table 49** ▪ ListDestroy Return Values

| Return Value                 | Description                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 0                            | Indicates that the function successfully destroyed the list, removing it from memory.                                                      |
| < 0                          | Indicates that the function was unable to destroy the list.                                                                                |
| ISERR_LIST_NOSUCHLIST (-501) | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListDestroy Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListCreate and ListDestroy functions.
```

```

*
* ListCreate is called to create a number list. ListDestroy
* is called to destroy it.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListDestroy(HWND);

function ExFn_ListDestroy(hMSI)
    LIST listID;
    NUMBER nvItem;
begin

    // Create an empty number list.
    listID = ListCreate (NUMBERLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add the number 1078 to the list.
    ListAddItem (listID, 1078, AFTER);

    // Add the number 304 to the list
    ListAddItem (listID, 304, AFTER);

    // Retrieve the current item in the list (304).
    ListCurrentItem (listID, nvItem);

    // Display the current item.
    sprintfBox (INFORMATION, "ListCreate",
        "Current item in list: %d", nvItem);

    // Retrieve the first item in the list (1078).
    ListGetFirstItem (listID, nvItem);

    // Display the first item.
    sprintfBox (INFORMATION, "ListCreate",
        "First item in list: %d", nvItem);

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## ListFindItem

The **ListFindItem** function searches for a specific element in a number list, starting at the current element and continuing through the list from that point. If you want to start the search from the beginning of the list, use the [ListGetFirstItem](#) function. When ListFindItem finds the element, it becomes the current element in the list.

**Note** ▪ The `ListFindItem` function works only with number lists.

## Syntax

```
ListFindItem ( listID, nItem );
```

## Parameters

**Table 50** ▪ ListFindItem Parameters

| Parameter     | Description                             |
|---------------|-----------------------------------------|
| <b>listID</b> | Specifies the number list to search.    |
| <b>nItem</b>  | Specifies the item to find in the list. |

## Return Values

**Table 51** ▪ ListFindItem Return Values

| Return Value                        | Description                                                                                                                                        |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | The function successfully found the requested element.                                                                                             |
| <b>&lt; 0</b>                       | An error prevented the function from searching the specified list. This error occurs, for example, if the list specified by listID does not exist. |
| <b>END_OF_LIST (1)</b>              | The function searched to the end of the list and did not find the requested element.                                                               |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | A list with the specified ID does not exist. Valid list IDs are return values from the <b>ListCreate</b> function.                                 |

## ListFindItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListFindItem function.
*
* This script creates a number list and adds three numbers
* to it. The user is then asked to guess one of the numbers.
```

```

* ListFindItem is called to search the list for the number the
* user entered. A message box is displayed to tell the user
* whether the guess was right or wrong.
*
\*-----*/

#define TITLE_TEXT "ListFindItem Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListFindItem(HWND);

function ExFn_ListFindItem(hMSI)
    STRING svItem;
    NUMBER nItem, nResult;
    LIST listID;
begin

            endif;
        endif;
    endif;
end;

```

```

endif;

// Remove list from memory.
ListDestroy (listID);

end;

```

## ListFindKeyValueString

The **ListFindKeyValueString** function searches a string or number list for a specified value. It returns a value from an additional list that corresponds with the position of the found string in the first list. This enables you to search lists of key-value pairs for a particular key and get the corresponding value.

### Syntax

```
ListFindKeyValueString (byval LIST listKeys, byval LIST listValues, byval string szKey, byref string svValue);
```

## Parameters

**Table 52** ▪ ListFindKeyValueString Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listKeys</b>   | <p>Indicate the list of keys to be searched. You can specify a string or number list. The list must be initialized by calling <b>ListCreate</b> before calling <b>ListFindKeyValueString</b>.</p> <p>Note that the starting point for the search is always the beginning of the list, regardless of the current position of the list. When the function returns, the current position in the list is the found element.</p>                                                                     |
| <b>listValues</b> | <p>Indicate the list of values that corresponds with the list of keys. You can specify a string or number list. The list must be initialized by calling <b>ListCreate</b> before calling <b>ListFindKeyValueString</b>.</p> <p>Note that listKeys and listValues do not necessarily need to be the same type of list.</p>                                                                                                                                                                       |
| <b>szKey</b>      | <p>Specify the string for which you want to search.</p> <p>If listKeys is a number list, szKey is converted to a number by using the <b>StrToNum</b> function, which is then used to search the list.</p> <p><b>ListFindKeyValueString</b> calls <b>ListFindString</b> (if the list is a string list) or <b>ListFindItem</b> (if the list is a number list) to search the list. Searches for string lists are case-sensitive, since <b>ListFindString</b> performs case-sensitive searches.</p> |
| <b>svValue</b>    | <p>The value from the second list is returned in this parameter. If listValues is a number list, the number is converted to a string using <b>NumToStr</b> and then passed back as a string.</p>                                                                                                                                                                                                                                                                                                |

## Return Values

**Table 53** ▪

| Return Value                        | Description                                                                                                                                        |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | The function successfully found the requested element.                                                                                             |
| <b>&lt; 0</b>                       | An error prevented the function from searching the specified list. This error occurs, for example, if the list specified by listID does not exist. |
| <b>END_OF_LIST (1)</b>              | The function searched to the end of the list and did not find the requested element.                                                               |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | A list with the specified ID does not exist. Valid list IDs are return values from the <b>ListCreate</b> function.                                 |

# ListFindString

The **ListFindString** function searches for a specified element in a string list, starting at the current element and continuing from that point. If you want to start the search from the beginning of the string list, call the [ListGetFirstString](#) function. When ListFindString finds the string, it becomes the current element in the list.

**Note** ▪ The ListFindString function performs a case-sensitive comparison of the strings, and works only with string lists.

## Syntax

```
ListFindString ( listID, szString );
```

## Parameters

**Table 54** ▪ ListFindString Parameters

| Parameter       | Description                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>   | Specifies the string list to search.                                                                                         |
| <b>szString</b> | Specifies the string to find in the list. InstallShield performs a case-sensitive comparison when searching for this string. |

## Return Values

**Table 55** ▪ ListFindString Return Values

| Return Value                        | Description                                                                                                                                                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully found the requested element.                                                                                                 |
| <b>&lt; 0</b>                       | Indicates that an error prevented the function from searching the specified list. This error will occur, for example, if the list specified by listID does not exist. |
| <b>END_OF_LIST (1)</b>              | Indicates that InstallShield searched to the end of the list and did not find the requested element.                                                                  |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function.                            |

## ListFindString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the ListFindString function.
 *
 * This script prompts the user to input the name of a program
 * folder on the target system. ListFindString is then called
 * to search for this folder name in a list that contains all
 * folder names on the target system. A message is displayed
 * to report the results of the search.
 *
\*-----*/

#define TITLE_TEXT "ListFindString Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_ListFindString(HWND);

function ExFn_ListFindString(hMSI)
    STRING szString;
    LIST listID, listSubfoldersID;
    NUMBER nResult;
begin

    // Create string lists
    listID = ListCreate (STRINGLIST);
    listSubfoldersID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) || (listSubfoldersID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Fill the list with the names of program folders.
    GetFolderNameList (FOLDER_PROGRAMS, listID, listSubfoldersID);

    // Prompt user to enter a folder name.
    AskText ("Please enter the name of an existing program folder:",
        "", szString);

    // Make the first list element the current element
    // so ListFindItem will search from the top of the list.
    ListSetIndex (listSubfoldersID, 0);

    // Search the list for the folder name entered by the user.
    // Reminder: The string comparison is case sensitive.
    nResult = ListFindString (listSubfoldersID, szString);

    // Report the search result.
    if (nResult < 0) then
        MessageBox ("ListFindString failed.", SEVERE);
    elseif (nResult = END_OF_LIST) then

```

```

        SprintfBox (WARNING, TITLE_TEXT, "%s could not be found.", szString);
    elseif (nResult = 0) then
        SprintfBox (INFORMATION, TITLE_TEXT, "ListFindString found: %s.",
                    szString);
    endif;

    // Remove list from memory.
    ListDestroy (listID);
    ListDestroy (listSubfoldersID);

end;

```

## ListGetFirstItem

The **ListGetFirstItem** function retrieves the first element from a number list. The first item becomes the current element in the list.

---

**Note** ▪ *The ListGetFirstItem function works only with number lists.*

### Syntax

```
ListGetFirstItem ( listID, nvItem );
```

## Parameters

**Table 56** ▪ ListGetFirstItem Parameters

| Parameter     | Description                                                         |
|---------------|---------------------------------------------------------------------|
| <b>listID</b> | Specifies the number list from which to retrieve the first element. |
| <b>nvItem</b> | Returns the first element of the number list.                       |

## Return Values

**Table 57** ▪ ListGetFirstItem Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully retrieved the first element in a number list.                                                     |
| <b>-1</b>                           | Indicates that an error prevented the function from retrieving the first element in a number list.                                         |
| <b>END_OF_LIST (1)</b>              | Indicates that the list is empty.                                                                                                          |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListGetFirstItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListGetFirstItem and ListGetNextItem
* functions.
*
* This script starts by creating a number list and adding
* three numbers to it. ListGetFirstItem is called then to get
* the first number from the list. This call also makes the
* first number the current element. A loop process follows to
* display the number retrieved from the list and then call
* ListGetNextItem to get the next number. The loop executes
* until ListGetFirstItem or ListGetNextItem reaches the end
```

```

    * of the list.
    *
    \*-----*/

#define TITLE_TEXT "ListGetFirstItem & ListGetNextItem"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_ListGetFirstItem(HWND);

function ExFn_ListGetFirstItem(hMSI)
    STRING szMsg;
    LIST listID;
    NUMBER nvItem, nResult;
begin

    // Create a number list.
    listID = ListCreate (NUMBERLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add three numbers to the list.
    ListAddItem (listID, 1024, AFTER);
    ListAddItem (listID, 360, AFTER);
    ListAddItem (listID, 777, AFTER);

    // Get the first number from the list.
    nResult = ListGetFirstItem (listID, nvItem);

    // Loop while not at end of list.
    while (nResult != END_OF_LIST)
        // Display the number retrieved from the list.
        sprintfBox (INFORMATION, TITLE_TEXT, "%i", nvItem);

        // Get the next number from the list.
        nResult = ListGetNextItem (listID, nvItem);
    endwhile;

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## ListGetFirstString

The **ListGetFirstString** function retrieves the first element from a string list. The first string becomes the current element in the list.

The ListGetFirstString function works only with string lists.

## Syntax

```
ListGetFirstString ( listID, svString );
```

## Parameters

**Table 58** ▪ ListGetFirstString Parameters

| Parameter       | Description                                                         |
|-----------------|---------------------------------------------------------------------|
| <b>listID</b>   | Specifies the string list from which to retrieve the first element. |
| <b>svString</b> | Returns the first element of the string list.                       |

## Return Values

**Table 59** ▪ ListGetFirstString Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully retrieved the first element in a string list.                                                     |
| <b>-1</b>                           | Indicates that an error prevented the function from retrieving the first element in a string list.                                         |
| <b>END_OF_LIST (1)</b>              | Indicates that the list is empty.                                                                                                          |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListGetFirstString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListGetFirstString and ListGetNextString
* functions.
*
* This script starts by creating a string list and adding
* program folder names to it. ListGetFirstString is called
* then to get the first string from the list. This call also
* makes the first string the current element. A loop process
```

```

* follows to display the string retrieved from the list and
* then call ListGetNextString to get the next string. The
* loop executes until ListGetFirstString or ListGetNextString
* reaches the end of the list.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListGetFirstString(HWND);

function ExFn_ListGetFirstString(hMSI)
    STRING svString;
    LIST listID;
    NUMBER nResult;
begin

    // Create a string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Get the names of the program folders into a list.
    if GetGroupNameList(listID) < 0 then ;
        // Report ListCreate failure.
        MessageBox ("Unable to retrieve program folder names.", SEVERE);
    else
        // Get the first string in the list.
        nResult = ListGetFirstString (listID, svString);

        // Loop while list items continue to be retrieved.
        while (nResult != END_OF_LIST)
            // Display the current element.
            MessageBox (svString, INFORMATION);

            // Get the next string in the list.
            nResult = ListGetNextString (listID, svString);
        endwhile;
    endif;

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## ListGetIndex

**Project** ▪ This information applies to InstallScript projects.

The **ListGetIndex** function retrieves the index of the specified list's current element. Index numbers starts at zero (0).

## Syntax

```
ListGetIndex ( listID, nIndex );
```

## Parameters

**Table 60** ▪ ListGetIndex Parameters

| Parameter     | Description                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------|
| <b>listID</b> | Specifies the ID of the string or number list whose current element's index is to be retrieved. |
| <b>nIndex</b> | Returns the index of the list's current element.                                                |

## Return Values

**Table 61** ▪ ListGetIndex Return Values

| Return Value                 | Description                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b>   | Indicates that the function successfully retrieved the index of the list's current element.                                                |
| <b>&lt; ISERR_SUCCESS</b>    | Indicates that the function was unable to retrieve the index of the list's current element.                                                |
| <b>ISERR_LIST_NOSUCHLIST</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## Additional Information

- Use [ListCurrentItem](#) and [ListCurrentString](#) to retrieve the value of the current element.
- This function works on both string and number lists.

# ListGetNextItem

The **ListGetNextItem** function retrieves the item after the current element in a number list. The retrieved item becomes the current element in the list.

**Note** ▪ The *ListGetNextItem* function works only with number lists.

## Syntax

```
ListGetNextItem ( listID, nvItem );
```

## Parameters

**Table 62** ▪ ListGetNextItem Parameters

| Parameter     | Description                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b> | Specifies the number list from which to retrieve the next element.                                                       |
| <b>nvItem</b> | Returns the item that follows the current element in the number list. That item becomes the current element in the list. |

## Return Values

**Table 63** ▪ ListGetNextItem Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully retrieved the element after the current element in a number list.                                 |
| <b>-1</b>                           | Indicates that an error prevented the function from retrieving the specified element in a number list.                                     |
| <b>END_OF_LIST (1)</b>              | Indicates that the current item is the last element in the list.                                                                           |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListGetNextItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListGetFirstItem and ListGetNextItem
* functions.
```

```

*
* This script starts by creating a number list and adding
* three numbers to it. ListGetFirstItem is called then to get
* the first number from the list. This call also makes the
* first number the current element. A loop process follows to
* display the number retrieved from the list and then call
* ListGetNextItem to get the next number. The loop executes
* until ListGetFirstItem or ListGetNextItem reaches the end
* of the list.
*
\*-----*/

#define TITLE_TEXT "ListGetFirstItem & ListGetNextItem"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListGetNextItem(HWND);

function ExFn_ListGetNextItem(hMSI)
    STRING szMsg;
    LIST listID;
    NUMBER nvItem, nResult;
begin

    // Create a number list.
    listID = ListCreate (NUMBERLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add three numbers to the list.
    ListAddItem (listID, 1024, AFTER);
    ListAddItem (listID, 360, AFTER);
    ListAddItem (listID, 777, AFTER);

    // Get the first number from the list.
    nResult = ListGetFirstItem (listID, nvItem);

    // Loop while not at end of list.
    while (nResult != END_OF_LIST)
        // Display the number retrieved from the list.
        sprintfBox (INFORMATION, TITLE_TEXT, "%i", nvItem);

        // Get the next number from the list.
        nResult = ListGetNextItem (listID, nvItem);
    endwhile;

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

# ListGetNextString

The **ListGetNextString** function retrieves the element after the current element in a string list. The retrieved element becomes the current element in the list.

---

**Note** ▪ The *ListGetNextString* function works only with string lists.

## Syntax

```
ListGetNextString ( listID, svString );
```

## Parameters

**Table 64** ▪ ListGetNextString Parameters

| Parameter       | Description                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>   | Specifies the string list from which to retrieve the next element.                                                           |
| <b>svString</b> | Returns the string that follows the current element of the string list. This string becomes the current element in the list. |

## Return Values

**Table 65** ▪ ListGetNextString Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully retrieved the element after the current element in a string list.                                 |
| <b>-1</b>                           | Indicates that an error prevented the function from retrieving the specified element in a string list.                                     |
| <b>END_OF_LIST (1)</b>              | Indicates that the current item is the last element in the list.                                                                           |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListGetNextString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListGetFirstString and ListGetNextString
* functions.
*
* This script starts by creating a string list and adding
* program folder names to it. ListGetFirstString is called
* then to get the first string from the list. This call also
```

```

* makes the first string the current element. A loop process
* follows to display the string retrieved from the list and
* then call ListGetNextString to get the next string. The
* loop executes until ListGetFirstString or ListGetNextString
* reaches the end of the list.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListGetNextString(HWND);

function ExFn_ListGetNextString(hMSI)
    STRING svString;
    LIST listID;
    NUMBER nResult;
begin

    // Create a string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Get the names of the program folders into a list.
    if GetGroupNameList(listID) < 0 then ;
        // Report ListCreate failure.
        MessageBox ("Unable to retrieve program folder names.", SEVERE);
    else
        // Get the first string in the list.
        nResult = ListGetFirstString (listID, svString);

        // Loop while list items continue to be retrieved.
        while (nResult != END_OF_LIST)
            // Display the current element.
            MessageBox (svString, INFORMATION);

            // Get the next string in the list.
            nResult = ListGetNextString (listID, svString);
        endwhile;
    endif;

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## ListGetType

The **ListGetType** function determines whether a list is a STRINGLIST or NUMBERLIST.

## Syntax

```
ListGetType (listID);
```

## Parameters

**Table 66** ▪ ListGetType Parameters

| Parameter     | Description                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b> | Specifies the name of a string list. The list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> . |

## Return Values

**Table 67** ▪ ListGetType Return Values

| Return Value      | Description                                                           |
|-------------------|-----------------------------------------------------------------------|
| <b>STRINGLIST</b> | Indicates that the list is a string list.                             |
| <b>NUMBERLIST</b> | Indicates that the list is a number list.                             |
| <b>&lt;0</b>      | Indicates that the function was unable to determine the type of list. |

## ListGetType Example

**Note** ▪ The list identified by listID must already have been initialized by a call to [ListCreate](#)<[LangrefListCreate.htm](#)>.

```
//Sample code
LIST listID;
int      nType;

program
    listID = ListCreate(STRINGLIST);
    if (LIST_NULL != listID) then
        nType = ListGetType(listID);
        if (STRINGLIST = nType) then
            MessageBox("It is a STRINGLIST", INFORMATION);
        else
            MessageBox("It is a NUMBERLIST", INFORMATION);
        endif;
    endif;
    ListDestroy(listID);

    listID = ListCreate(NUMBERLIST);
    if (LIST_NULL != listID) then
```

```

nType = ListGetType(listID);
if (STRINGLIST = nType) then
    MessageBox("It is a STRINGLIST", INFORMATION);
else
    MessageBox("It is a NUMBERLIST", INFORMATION);
endif;
endif;
ListDestroy(listID);
endprogram

```

## ListReadFromFile

The **ListReadFromFile** function reads a text file into a list. After you load a text file into a list, you can use it for various functions in the setup, such as displaying a README file at the end of the setup or writing a string list to the disk with [ListWriteToFile](#).

This function detects the newline characters at the end of each string and uses the characters as delimiters for each element in the list.

---

**Note** ▪ The *ListReadFromFile* function operates on string lists and text files only.

### Syntax

```
ListReadFromFile ( listID, szFile );
```

## Parameters

**Table 68** ▪ ListReadFromFile Parameters

| Parameter     | Description                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b> | Returns a list of the lines read from the file specified by szFile. The list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> . |
| <b>szFile</b> | Specifies the fully qualified name of the file that will be read into the list.                                                                                                |

## Return Values

**Table 69** ▪ ListReadFromFile Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully read the lines of text in a file into a list.                                                     |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |
| <b>&lt; 0</b>                       | Indicates that the function was unable to read the lines from a text file into a list.                                                     |

## ListReadFromFile Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListReadFromFile and ListWriteToFile
* functions.
*
* ListReadFromFile is called to read and display the
* Autoexec.bat file. After the list has been displayed,
* a remark is appended to the end of the list and the list
* is written to a new file. The original file remains
* unchanged.
*
* Note: In order for this script to run correctly, there must
```

```

*      be a batch file named Autoexec.bat in the root
*      directory of drive C.
*
\*-----*/

#define OLD_FILE "C:\\Autoexec.bat"
#define NEW_FILE "C:\\Autoexec.lst"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListReadFromFile(HWND);

function ExFn_ListReadFromFile(hMSI)
    LIST listID;
begin

    // Create a string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Read the file into a string list.
    if (ListReadFromFile (listID, OLD_FILE) < 0) then
        // Report ListReadFromFile failure.
        MessageBox ("Unable to read" + OLD_FILE + ".", SEVERE);
    else
        // Display the list.
        SdShowInfoList ("Demo", "The example list file:", listID);

        // Add a new string to the list.
        ListAddString (listID, "REM Added by IS setup.", AFTER);

        // Write the list to a file.
        if (ListWriteToFile (listID, NEW_FILE) < 0) then
            MessageBox ("Unable to write list to " + NEW_FILE + ".", SEVERE);
        else
            MessageBox ("Successfully wrote list " + NEW_FILE + ".", INFORMATION);
        endif;
    endif;

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## ListSetCurrentItem

The **ListSetCurrentItem** function assigns the value of `nItem` to the current element in a number list.

**Note** ▪ The `ListSetCurrentItem` function works only with number lists.

## Syntax

```
ListSetCurrentItem ( listID, nItem );
```

## Parameters

**Table 70** ▪ ListSetCurrentItem Parameters

| Parameter     | Description                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b> | Specifies the name of a number list whose current element is to be updated. The list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> . |
| <b>nItem</b>  | Specifies the numeric value that will replace the current element.                                                                                                                     |

## Return Values

**Table 71** ▪ ListSetCurrentItem Return Values

| Return Value                        | Description                                                                                                                                |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully updated the current element in a number list.                                                     |
| <b>&lt; 0</b>                       | Indicates that the function was unable to update the current element in a number list.                                                     |
| <b>END_OF_LIST (1)</b>              | Indicates that the list is empty.                                                                                                          |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function. |

## ListSetCurrentItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* Demonstrates the ListSetCurrentItem function.
*
* This script first creates a number list and then adds two
* numbers to it. Next, the list is displayed in a dialog.
* ListSetCurrentItem is then called to update the value of
* the current element in the list. Finally, this new list is
* displayed.
*
\*-----*/

#define MSG_TEXT  "Elements in listID:\n\n"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListSetCurrentItem(HWND);

function ExFn_ListSetCurrentItem(hMSI)
    LIST  listID;
    NUMBER nItem, nvResult, nvItem;
    STRING szMsg, svItem;
begin

    // Create an empty number list.
    listID = ListCreate (NUMBERLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add two numbers to the list.
    ListAddItem (listID, 1024, AFTER);
    ListAddItem (listID, 360, AFTER);

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Start building the message to report the numbers.
    szMsg = MSG_TEXT;

    // Get the numbers and add them to the message.
    nvResult = ListGetFirstItem (listID, nvItem);
    while (nvResult != END_OF_LIST)
        NumToStr (svItem, nvItem);
        szMsg = szMsg + svItem + " ";
        nvResult = ListGetNextItem (listID, nvItem);
    endwhile;

    // Display the numbers.
    MessageBox (szMsg, INFORMATION);

    // Replace the value of the second item with a new value.
    if (ListSetCurrentItem (listID, 777) < 0) then

```

```

        MessageBox ("ListSetCurrentItem failed.", SEVERE);
    else
        // Start building the message to report the numbers.
        szMsg = MSG_TEXT;

        // Get the numbers and add them to the message.
        nvResult = ListGetFirstItem (listID, nvItem);

        while (nvResult != END_OF_LIST)
            NumToStr (svItem, nvItem);
            szMsg = szMsg + svItem + " ";
            nvResult = ListGetNextItem (listID, nvItem);
        endwhile;

        // Display the numbers.
        MessageBox (szMsg, INFORMATION);
    endif;

    // Remove list from memory.
    ListDestroy (listID);

end;

```

## ListSetCurrentString

The **ListSetCurrentString** function assigns the value of szString to the current element in the string list.

---

**Note** ▪ The *ListSetCurrentString* function works only with string lists.

### Syntax

```
ListSetCurrentString ( listID, szString );
```

## Parameters

**Table 72** ▪ ListSetCurrentString Parameters

| Parameter       | Description                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>   | Specifies the name of a string list whose current element is to be updated. The list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> . |
| <b>szString</b> | Specifies the string value that will replace the current element.                                                                                                                      |

## Return Values

**Table 73** ▪ ListSetCurrentString Return Values

| Return Value                        | Description                                                                                                                                                                         |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully updated the current element in a number list.                                                                                              |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <a href="#">ListCreate</a> function.                                          |
| <b>&lt; 0</b>                       | Indicates that the function was unable to update the current element in a number list. A common reason for this error is that the index is out of range of available list elements. |

## ListSetCurrentString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListSetCurrentString function.
*
* In this script, two strings are added to an empty list.
* The list is then displayed in a dialog. Next,
* ListSetCurrentString is called to replace the current
* element. The list is then displayed again in a
* dialog.
*
```

```

\*-----*/

#define TITLE_TEXT "ListSetCurrentString Example"
#define MSG_TEXT   "Elements in listID:"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListSetCurrentString(HWND);

function ExFn_ListSetCurrentString(hMSI)
    LIST listID;
begin

    // Create an empty string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Add two strings to the list.
    ListAddString (listID, "Keyboard", AFTER);
    ListAddString (listID, "Monitor", AFTER);

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Display the list.
    SdShowInfoList (TITLE_TEXT, MSG_TEXT, listID);

    // Replace the value of the second item with a new value.
    if (ListSetCurrentString(listID, "Mouse") < 0) then
        MessageBox ("ListSetCurrentString failed.", SEVERE);
    endif;

    // Display the new altered list.
    SdShowInfoList (TITLE_TEXT, MSG_TEXT, listID);

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## ListSetIndex

The **ListSetIndex** function makes a specific element in a string or number list the current element, using an index. You can also use constants to traverse a list one element at a time or to jump to the beginning or end of a list. By using indices to access items in a list, you can treat numeric and string lists as arrays.

After you set the indexed element as the current element, you can use either the [ListCurrentItem](#) or [ListCurrentString](#) function in the script to retrieve the value of the indexed (current) item.

---

**Note** ▪ *The `ListSetIndex` function works with both string and number lists.*

## Syntax

```
ListSetIndex (listID, nIndex);
```

## Parameters

**Table 74** ▪ ListSetIndex Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b> | Specifies the name of the string or number list whose index is to be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>nIndex</b> | <p>Specifies the number of the element you want to set as the current element. List element numbering begins at zero (0). For example, if you enter 5 in the parameter nIndex, the item in the sixth physical location in the list becomes the current element.</p> <p>Pass a numeric value or one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>LISTFIRST</b>—Moves to the first element in the list.</li> <li>• <b>LISTLAST</b>—Moves to the last element in the list.</li> <li>• <b>LISTNEXT</b>—Moves to the next element in the list.</li> <li>• <b>LISTPREV</b>—Moves to the previous element in the list.</li> </ul> |

## Return Values

**Table 75** ▪ ListSetIndex Return Values

| Return Value                        | Description                                                                                                                       |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | Indicates that the function successfully updated the current element in the list.                                                 |
| <b>&lt; 0</b>                       | Indicates that the function was unable to update the current element the list.                                                    |
| <b>END_OF_LIST (1)</b>              | Indicates that the index is out of range of available list elements.                                                              |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the <b>ListCreate</b> function. |

## ListSetIndex Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the ListSetIndex function.
 *
 * This example script displays the last three items from a list
 * of program folders.
 *
 * Note: If the target system has a shell other than Explorer,
 *       the GetGroupNameList function may return an error.
 *
\*-----*/

#define TITLE_TEXT "ListSetIndex Example"
#define MSG_TEXT   "Please note the last three items in this list."

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListSetIndex(HWND);

function ExFn_ListSetIndex(hMSI)
    STRING    svString;
    LIST      listID;
    NUMBER    nResult, nIndex;
begin

    // Create string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Get the names of the program folders into a list.
    if GetGroupNameList (listID) < 0 then ;
        // Report ListCreate failure.
        MessageBox ("Unable to retrieve program folder names.", SEVERE);
    else
        // Display the list.
        SdShowInfoList( TITLE_TEXT, MSG_TEXT, listID);

        // Make the third item from the end of the list the current
        // the current element. If there are fewer than three items,
        // display them all. List indexing begins at 0.
        nIndex = ListCount (listID);

        if nIndex > 3 then

```

```

        nIndex = nIndex - 3;
    endif;

    nResult = ListSetIndex (listID, nIndex);

    // Loop while there are items to display.
    while (nResult != END_OF_LIST)
        // Get the current list item.
        ListCurrentString (listID, svString);

        // Display the current list item.
        MessageBox (svString, INFORMATION);

        // Make the next item the current item.
        nResult = ListSetIndex (listID, LISTNEXT);
    endwhile;
endif;

// Remove the list from memory.
ListDestroy (listID);

end;

```

## ListValid

The **ListValid** function indicates whether the list specified by listID is valid, that is, whether it has been initialized by calling **ListCreate** and not destroyed by calling **ListDestroy**. This function works with both string and number lists.

### Syntax

```
ListValid ( listID );
```

## Parameters

**Table 76** ▪ ListValid Parameters

| Parameter     | Description                                        |
|---------------|----------------------------------------------------|
| <b>listID</b> | Specifies the string or number list to be checked. |

## Return Values

**Table 77** ▪ ListValid Return Values

| Return Value                 | Description                                       |
|------------------------------|---------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b>   | Indicates that the list is valid.                 |
| <b>&lt; ISERR_SUCCESS</b>    | Indicates that the list is not valid.             |
| <b>ISERR_LIST_NOSUCHLIST</b> | Indicates that the list has not been initialized. |

## ListValid Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the ListValid function.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

function OnBegin()
    LIST listID;
    number nListValid;
begin
    // Create an empty number list.
    listID = ListCreate (NUMBERLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Check whether the list ID is valid.
    nListValid = ListValid (listID);
    if (nListValid >= ISERR_SUCCESS) then
        MessageBox ("List ID is valid.", INFORMATION);
    else

```

```

        MessageBox ("List ID is not valid.", INFORMATION);
    endif;

    // Remove the list from memory.
    ListDestroy (listID);

    // Check whether the list ID is valid.
    nListValid = ListValid (listID);
    if (nListValid >= ISERR_SUCCESS) then
        MessageBox ("List ID is valid.", INFORMATION);
    else
        MessageBox ("List ID is not valid.", INFORMATION);
    endif;

    // If you cut and paste this sample script into a project
    // and run it, the following line aborts execution of the script.
    abort;
end;

```

## ListValidType

The **ListValidType** function indicates whether the list specified by listID is of the specified type and is valid, that is, whether it has been initialized by calling [ListCreate](#) and not destroyed by calling [ListDestroy](#).

### Syntax

```
ListValidType ( listID, nType );
```

## Parameters

**Table 78** ▪ ListValidType Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b> | Specifies the string or number list to be checked.                                                                                                                                                                                                                                      |
| <b>nType</b>  | Specifies the list type to which the specified list is compared. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>NUMBERLIST</b>—Specifies a number list.</li> <li>• <b>STRINGLIST</b>—Specifies a string list.</li> </ul> |

## Return Values

**Table 79** ▪ ListValidType Return Values

| Return Value                   | Description                                                           |
|--------------------------------|-----------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b>     | Indicates that the list is valid and is of the specified type.        |
| <b>&lt; ISERR_SUCCESS</b>      | Indicates that the list is not valid or is not of the specified type. |
| <b>ISERR_LIST_NOSUCHLIST</b>   | Indicates that the list has not been initialized.                     |
| <b>ISERR_LIST_TYPEMISMATCH</b> | Indicates that the list is not of the specified type.                 |

## ListValidType Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the ListValidType function.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

function OnBegin()
    LIST listID;
    number nListValidType;
begin
    // Create an empty string list.

```

```

listID = ListCreate (STRINGLIST);

// If an error occurred, report it; then terminate.
if (listID = LIST_NULL) then
    MessageBox ("Unable to create list.", SEVERE);
    abort;
endif;

// Check whether the list ID is valid and what type it is.
nListValidType = ListValidType (listID, NUMBERLIST);
if (nListValidType >= ISERR_SUCCESS) then
    MessageBox ("List ID is valid and is a number list.",
        INFORMATION);
else
    nListValidType = ListValidType (listID, STRINGLIST);
    if (nListValidType >= ISERR_SUCCESS) then
        MessageBox ("List ID is valid and is a string list.",
            INFORMATION);
    else
        MessageBox ("List ID is not valid.", INFORMATION);
    endif;
endif;

// Remove the list from memory.
ListDestroy (listID);

// Check whether the list ID is valid and what type it is.
nListValidType = ListValidType (listID, NUMBERLIST);
if (nListValidType >= ISERR_SUCCESS) then
    MessageBox ("List ID is valid and is a number list.",
        INFORMATION);
else
    nListValidType = ListValidType (listID, STRINGLIST);
    if (nListValidType >= ISERR_SUCCESS) then
        MessageBox ("List ID is valid and is a string list.",
            INFORMATION);
    else
        MessageBox ("List ID is not valid.", INFORMATION);
    endif;
endif;

// If you cut and paste this sample script into a project
// and run it, the following line aborts execution of the script.
abort;
end;

```

## ListWriteToFile

The **ListWriteToFile** function writes a string list to a text file. Each string appears on a separate line in the text file.

**Note** - Note if the file already exists and the pre-existing file is Unicode, it writes the file as Unicode. Otherwise, it writes the file as ANSI.

## Syntax

```
ListWriteToFile ( listID, szFileName );
```

## Parameters

**Table 80** ▪ ListWriteToFile Parameters

| Parameter         | Description                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>     | Specifies the name of a string list to write into a text file.                                                                                                                      |
| <b>szFileName</b> | Specifies the fully qualified name of the file to which the string list is to be written. If the file does not exist, it is created. If the file already exists, it is overwritten. |

## Return Values

**Table 81** ▪ ListWriteToFile Return Values

| Return Value                        | Description                                                                                                                |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                            | The function was successful.                                                                                               |
| <b>ISERR_LIST_NOSUCHLIST (-501)</b> | Indicates that a list with the specified ID does not exist. Valid list IDs are return values from the ListCreate function. |
| <b>&lt; 0</b>                       | The function failed.                                                                                                       |

## ListWriteToFile Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ListReadFromFile and ListWriteToFile
* functions.
*
* ListReadFromFile is called to read and display the
* Autoexec.bat file. After the list has been displayed,
* a remark is appended to the end of the list and the list
* is written to a new file. The original file remains
* unchanged.
```

```

*
* Note: In order for this script to run correctly, there must
*       be a batch file named Autoexec.bat in the root
*       directory of drive C.
*
\*-----*/

#define OLD_FILE "C:\\Autoexec.bat"
#define NEW_FILE "C:\\Autoexec.lst"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ListWriteToFile(HWND);

function ExFn_ListWriteToFile(hMSI)
    LIST listID;
begin
    // Create a string list.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then
        MessageBox ("Unable to create list.", SEVERE);
        abort;
    endif;

    // Read the file into a string list.
    if (ListReadFromFile (listID, OLD_FILE) < 0) then
        // Report ListReadFromFile failure.
        MessageBox ("Unable to read" + OLD_FILE + ".", SEVERE);
    else
        // Display the list.
        SdShowInfoList ("Demo", "The example list file:", listID);

        // Add a new string to the list.
        ListAddString (listID, "REM Added by IS setup.", AFTER);

        // Write the list to a file.
        if (ListWriteToFile (listID, NEW_FILE) < 0) then
            MessageBox ("Unable to write list to " + NEW_FILE + ".", SEVERE);
        else
            MessageBox ("Successfully wrote list " + NEW_FILE + ".", INFORMATION);
        endif;
    endif;

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

# ListWriteToFileEx

The **ListWriteToFileEx** function writes or appends a string list to a text file. Each string appears on a separate line in the text file.

## Syntax

```
ListWriteToFileEx ( listID, szFileName, nOptions );
```

## Parameters

**Table 82** ▪ ListWriteToFileEx Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>     | Specifies the name of a string list to write into a text file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>szFileName</b> | Specifies the fully qualified name of the file to which the string list is to be written. If the file does not exist, it is created. If the file already exists and the <code>LWTF_OPTION_APPEND_TO_FILE</code> is not specified for <code>nOptions</code> , it is overwritten.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>nOptions</b>   | <p>Specifies the encoding of the file and whether the string list can be appended to it if it already exists. Choose one or more of the following predefined constants:</p> <ul style="list-style-type: none"> <li>• <b>0</b>—If the file already exists and the pre-existing file is Unicode, writes the file as Unicode. Otherwise, writes the file as ANSI.</li> <li>• <b>LWTF_OPTION_WRITE_AS_UNICODE</b>—Writes the file as Unicode.</li> <li>• <b>LWTF_OPTION_WRITE_AS_ANSI</b>—Writes the file as ANSI.</li> <li>• <b>LWTF_OPTION_APPEND_TO_FILE</b>—Appends the contents of the list to the existing file. If the file does not exist, the function creates the file (which is the same behavior as if this option was not specified).</li> </ul> <p>You can combine two of these constants by using the bitwise OR operator (<code> </code>). For example, combine the <code>LWTF_OPTION_WRITE_AS_ANSI</code> and <code>LWTF_OPTION_APPEND_TO_FILE</code> constants if you want the contents of the string list to be append to the file as ANSI.</p> |

## Return Values

**Table 83** ▪ ListWriteToFileEx Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# LoadStringFromStringTable

The **LoadStringFromStringTable** function loads the value of the string entry specified by `szID` into `svString`. The

svString buffer is automatically resized if necessary to accommodate the string value.

## Syntax

```
LoadStringFromStringTable ( szID, svString );
```

## Parameters

**Table 84** ▪ LoadStringFromStringTable Parameters

| Parameter       | Description                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------|
| <b>szID</b>     | Specifies the string identifier of the string entry. Do not prefix the identifier with the at sign (@). |
| <b>svString</b> | Returns the string value associated with the identifier that is specified by szID.                      |

## Return Values

**Table 85** ▪ LoadStringFromStringTable Return Values

| Return Value               | Description                                                                   |
|----------------------------|-------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the string value was successfully loaded into svString.        |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the string identifier was not found in the String Editor view. |

## Additional Information

The **LoadStringFromStringTable** function is case-insensitive when it comes to string identifiers. Therefore, when you use a string identifier in your script, you do not necessarily need to match the case of the string identifier that is specified in the String Editor view. However, mixing case may prevent InstallShield from matching the string entries in the script to the corresponding string entries in the String Editor view at build time. Therefore, it is recommended that you use uppercase for all instances of string identifiers.

The **LoadStringFromStringTable** function is equivalent to the @ operator, with some exceptions:

- When you build a project that includes an InstallScript file (.rul) and the InstallScript code contains one or more references to string entries that use the @ operator, InstallShield validates the string entries at build time. If a string identifier in the project's InstallScript file is not defined as one of the project's string entries in the String Editor view, InstallShield displays build warning -7174. If you use **LoadStringFromStringTable**, InstallShield does not validate the string entries at build time; scripts that use **LoadStringFromStringTable** are assumed to have their own string-not-found error handling.
- If the specified identifier does not exist in the String Editor view, the @ operator causes a message box to be displayed at run time; **LoadStringFromStringTable** simply returns failure (< ISERR\_SUCCESS).

# LOBYTE

**Project** ▪ This information applies to InstallScript projects.

The **LOBYTE** function extracts the low-order byte from the 16-bit integer value specified by shValue.

## Syntax

```
LOBYTE ( shValue );
```

## Parameters

**Table 86** ▪ LOBYTE Parameters

| Parameter | Description                                                                 |
|-----------|-----------------------------------------------------------------------------|
| shValue   | Specifies the 16-bit integer from which you want to extract the lower byte. |

## Return Values

This function returns the low-order byte of the integer.

# LogReadCustomNumber

**Project** ▪ This information applies to InstallScript projects.

The **LogReadCustomNumber** function reads the number that is stored in the log file's custom logging section under the key name specified by szKey, and it returns the number data in nvValue.

## Syntax

```
LogReadCustomNumber( szKey, nvValue );
```

## Parameters

**Table 87** ▪ LogReadCustomNumber Parameters

| Parameter      | Description                                                                     |
|----------------|---------------------------------------------------------------------------------|
| <b>szKey</b>   | Specifies the key name that identifies the number being read from the log file. |
| <b>nvValue</b> | Returns the number data that is read from the log file.                         |

## Return Values

**Table 88** ▪ LogReadCustomNumber Return Values

| Return Value               | Description                                                                  |
|----------------------------|------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully read the number from the log file.  |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to read the number from the log file. |

## Additional Information

**LogReadCustomNumber** is not affected by whether logging is enabled or disabled. **LogReadCustomNumber** can read values that were entered with **LogWriteCustomNumber** and numbers that were entered as strings (for example, "123") with **LogWriteCustomString**. **LogReadCustomNumber** fails if used to read non-numeric data (for example, "123abc").

Custom log file entries do not affect maintenance or uninstallation of the product unless you add code to the script to read custom values and perform actions based on those values. **LogReadCustomString** cannot read data from the maintenance/uninstallation section of the log file (that is, the section where the installation automatically writes data, such as the files that are installed and the registry entries that are created, and from which it automatically reads data during maintenance or uninstallation).

To execute script code only when the product is being completely uninstalled, use an if-then statement:

```
if REMOVEALLMODE!=0 then
    /* this code is executed only during uninstallation */
endif;
```

To perform specific uninstallation actions when a particular feature is uninstalled, override the feature's UnInstalling event with the appropriate code.

## LogReadCustomNumber Example

**Project** ▪ This information applies to InstallScript projects.

```
//-----
//
// InstallShield Example Script
```

```
//
// Demonstrates the LogWriteCustomString, LogWriteCustomNumber,
// LogReadCustomString, and LogReadCustomNumber functions.
//
//-----

// during installation, write some custom data to the log file
function OnMoved( )
    LIST listDrives;
    NUMBER nDriveCount, nvIgnore;
    STRING svDate;
begin

if (!MAINTENANCE) then
    // get current date
    GetSystemInfo(DATE, nvIgnore, svDate);

    // get current count of available drive letters
    listDrives = ListCreate(STRINGLIST);
    GetValidDrivesList(listDrives, -1, -1);
    nDriveCount = ListCount(listDrives);
    ListDestroy(listDrives);

    // write custom data to .ilg log file
    LogWriteCustomString("InstallDate", svDate);
    LogWriteCustomNumber("DriveCount", nDriveCount);
endif;

end;

// during a complete uninstallation, read custom data back from the log file
function OnMoving( )
    NUMBER nvDriveCount;
    STRING svInstallDate;
begin

if (REMOVEALLMODE) then
    LogReadCustomNumber("DriveCount", nvDriveCount);
    LogReadCustomString("InstallDate", svInstallDate);
    sprintfBox(INFORMATION, "Custom Log Data",
        "During installation, the drive count " +
        "was %d, and the date was %s.",
        nvDriveCount, svInstallDate);
endif;

end;
```

## LogReadCustomString

**Project** ▪ This information applies to InstallScript projects.

**LogReadCustomString** reads the string that is stored the log file's custom logging section under the key name specified by `szKey`, and it returns the string data in `svValue`.

## Syntax

```
LogReadCustomString( szKey, svValue );
```

## Parameters

**Table 89** ▪ LogReadCustomString Parameters

| Parameter      | Description                                                                     |
|----------------|---------------------------------------------------------------------------------|
| <b>szKey</b>   | Specifies the key name that identifies the string being read from the log file. |
| <b>svValue</b> | Returns the string data that is read from the log file.                         |

## Return Values

**Table 90** ▪ LogReadCustomString Return Values

| Return Value               | Description                                                                  |
|----------------------------|------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully read the string from the log file.  |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to read the string from the log file. |

## Additional Information

**LogReadCustomString** is not affected by whether logging is enabled or disabled. **LogReadCustomString** can read values that were entered with either **LogWriteCustomString** or **LogWriteCustomNumber**.

Custom log file entries do not affect maintenance or uninstallation of the product unless you add code to the script to read custom values and perform actions based on those values. **LogReadCustomString** cannot read data from the maintenance/uninstallation section of the log file (that is, the section where the installation automatically writes data, such as the files that are installed and the registry entries that are created, and from which it automatically reads data during maintenance or uninstallation).

**Note** ▪ If you selected the **Show Password dialog box during setup initialization** check box in the Password & Copyright panel of the Release Wizard or selected Yes for the Show Password Dialog setting in the Releases view, the default code for the `OnCheckMediaPassword` event handler function calls **LogWriteCustomString** with `szKey` set to `MEDIA_PASSWORD_KEY` in order to store a password-protected installation's password (as entered by the end user) so that maintenance and upgrade operations do not require that the same password be reentered. That default code also calls **LogWriteCustomString** with `szKey` set to `MEDIA_PASSWORD_KEY` in order to check whether the password is already stored before querying the end user for the password.

To execute script code only when the product is being completely uninstalled, use an if-then statement:

```
if REMOVEALLMODE!=0 then
  /* this code is executed only during uninstallation */
```

```
endif;
```

To perform specific uninstallation actions when a particular feature is uninstalled, override the feature's UnInstalling event with the appropriate code.

## LogReadCustomString Example

**Project** ▪ This information applies to InstallScript projects.

```
//-----
//
//  InstallShield Example Script
//
//  Demonstrates the LogWriteCustomString, LogWriteCustomNumber,
//  LogReadCustomString, and LogReadCustomNumber functions.
//
//-----

// during installation, write some custom data to the log file
function OnMoved( )
    LIST listDrives;
    NUMBER nDriveCount, nvIgnore;
    STRING svDate;
begin

if (!MAINTENANCE) then
    // get current date
    GetSystemInfo(DATE, nvIgnore, svDate);

    // get current count of available drive letters
    listDrives = ListCreate(STRINGLIST);
    GetValidDrivesList(listDrives, -1, -1);
    nDriveCount = ListCount(listDrives);
    ListDestroy(listDrives);

    // write custom data to .ilg log file
    LogWriteCustomString("InstallDate", svDate);
    LogWriteCustomNumber("DriveCount", nDriveCount);
endif;

end;

// during a complete uninstallation, read custom data back from the log file
function OnMoving( )
    NUMBER nvDriveCount;
    STRING svInstallDate;
begin

if (REMOVEALLMODE) then
    LogReadCustomNumber("DriveCount", nvDriveCount);
    LogReadCustomString("InstallDate", svInstallDate);
    sprintfBox(INFORMATION, "Custom Log Data",
```

```

        "During installation, the drive count " +
        "was %d, and the date was %s.",
        nvDriveCount, svInstallDate);
endif;

end;

```

## LogWriteCustomNumber

**Project** ▪ This information applies to InstallScript projects.

**LogWriteCustomNumber** writes the number specified by `nValue` to the log file in the custom logging section under the key name specified by `szKey`.

### Syntax

```
LogWriteCustomNumber( szKey, nValue );
```

### Parameters

**Table 91** ▪ LogWriteCustomNumber Parameters

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                 |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>  | Specifies the key name that identifies the number being written to the log file. All key names written to a particular log file must be unique, regardless of whether they are written with <code>LogWriteCustomNumber</code> or <code>LogWriteCustomString</code> . If you specify a key name that already exists in the custom logging section, its value is overwritten. |
| <b>nValue</b> | Specifies the number to be written to the log file.                                                                                                                                                                                                                                                                                                                         |

### Return Values

**Table 92** ▪ LogWriteCustomNumber Return Values

| Return Value               | Description                                                                 |
|----------------------------|-----------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully wrote the number to the log file.  |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to write the number to the log file. |

### Additional Information

**LogWriteCustomNumber** fails if you call it while logging is disabled.

Custom log file entries do not affect maintenance or uninstallation of the product unless you add code to the script to read custom values and perform actions based on those values. **LogWriteCustomNumber** cannot write data to the maintenance/uninstallation section of the log file (that is, the section where the installation automatically writes data, such as the files that are installed and the registry entries that are created, and from which it automatically reads data during maintenance or uninstallation).

To execute script code only when the product is being completely uninstalled, use an if-then statement:

```
if REMOVEALLMODE!=0 then
    /* this code is executed only during uninstallation */
endif;
```

To perform specific uninstallation actions when a particular feature is uninstalled, override the feature's UnInstalling event with the appropriate code.

## LogWriteCustomNumber Example

**Project** ▪ This information applies to InstallScript projects.

```
//-----
//
// InstallShield Example Script
//
// Demonstrates the LogWriteCustomString, LogWriteCustomNumber,
// LogReadCustomString, and LogReadCustomNumber functions.
//
//-----

// during installation, write some custom data to the log file
function OnMoved( )
    LIST listDrives;
    NUMBER nDriveCount, nvIgnore;
    STRING svDate;
begin

if (!MAINTENANCE) then
    // get current date
    GetSystemInfo(DATE, nvIgnore, svDate);

    // get current count of available drive letters
    listDrives = ListCreate(STRINGLIST);
    GetValidDrivesList(listDrives, -1, -1);
    nDriveCount = ListCount(listDrives);
    ListDestroy(listDrives);

    // write custom data to .ilg log file
    LogWriteCustomString("InstallDate", svDate);
    LogWriteCustomNumber("DriveCount", nDriveCount);
endif;

end;
```

```
// during a complete uninstallation, read custom data back from the log file
function OnMoving( )
    NUMBER nvDriveCount;
    STRING svInstallDate;
begin

if (REMOVEALLMODE) then
    LogReadCustomNumber("DriveCount", nvDriveCount);
    LogReadCustomString("InstallDate", svInstallDate);
    sprintfBox(INFORMATION, "Custom Log Data",
        "During installation, the drive count " +
        "was %d, and the date was %s.",
        nvDriveCount, svInstallDate);
endif;

end;
```

## LogWriteCustomString

**Project** - This information applies to InstallScript projects.

**LogWriteCustomString** writes the string specified by szValue to the log file in the custom logging section under the key name specified by szKey.

### Syntax

```
LogWriteCustomString( szKey, szValue );
```

## Parameters

**Table 93** ▪ LogWriteCustomString Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>   | Specifies the key name that identifies the string being written to the log file. All key names written to a particular log file must be unique, regardless of whether they are written with LogWriteCustomString or LogWriteCustomNumber. If you specify a key name that already exists in the custom logging section, its value is overwritten. |
| <b>szValue</b> | Specifies the value to be written to the log file.                                                                                                                                                                                                                                                                                               |

## Return Values

**Table 94** ▪ LogWriteCustomString Return Values

| Return Value               | Description                                                                 |
|----------------------------|-----------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully wrote the string to the log file.  |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to write the string to the log file. |

## Additional Information

**LogWriteCustomString** fails if you call it while logging is disabled.

Custom log file entries do not affect maintenance or uninstallation of the product unless you add code to the script to read custom values and perform actions based on those values. **LogWriteCustomString** cannot write data to the maintenance/uninstallation section of the log file (that is, the section where the installation automatically writes data, such as the files that are installed and the registry entries that are created, and from which it automatically reads data during maintenance or uninstallation).

**Note** ▪ If you selected the **Show Password dialog box during setup initialization** check box in the Password & Copyright panel of the Release Wizard or selected Yes for the Show Password Dialog setting in the Releases view, the default code for the OnCheckMediaPassword event handler function calls **LogWriteCustomString** with szKey set to MEDIA\_PASSWORD\_KEY in order to store a password-protected installation's password (as entered by the end user) so that maintenance and upgrade operations do not require that the same password be reentered. That default code also calls **LogWriteCustomString** with szKey set to MEDIA\_PASSWORD\_KEY in order to check whether the password is already stored before querying the end user for the password.

To execute script code only when the product is being completely uninstalled, use an if-then statement:

```
if REMOVEALLMODE!=0 then
    /* this code is executed only during uninstallation */
endif;
```

To perform specific uninstallation actions when a particular feature is uninstalled, override the feature's UnInstalling event with the appropriate code.

## LogWriteCustomString Example

**Project** - This information applies to InstallScript projects.

```
//-----
//
// InstallShield Example Script
//
// Demonstrates the LogWriteCustomString, LogWriteCustomNumber,
// LogReadCustomString, and LogReadCustomNumber functions.
//
//-----

// during installation, write some custom data to the log file
function OnMoved( )
    LIST listDrives;
    NUMBER nDriveCount, nvIgnore;
    STRING svDate;
begin

if (!MAINTENANCE) then
    // get current date
    GetSystemInfo(DATE, nvIgnore, svDate);

    // get current count of available drive letters
    listDrives = ListCreate(STRINGLIST);
    GetValidDrivesList(listDrives, -1, -1);
    nDriveCount = ListCount(listDrives);
    ListDestroy(listDrives);

    // write custom data to .ilg log file
    LogWriteCustomString("InstallDate", svDate);
    LogWriteCustomNumber("DriveCount", nDriveCount);
endif;

end;

// during a complete uninstallation, read custom data back from the log file
function OnMoving( )
    NUMBER nvDriveCount;
    STRING svInstallDate;
begin

if (REMOVEALLMODE) then
    LogReadCustomNumber("DriveCount", nvDriveCount);
    LogReadCustomString("InstallDate", svInstallDate);
    sprintfBox(INFORMATION, "Custom Log Data",
        "During installation, the drive count " +
        "was %d, and the date was %s.",
        nvDriveCount, svInstallDate);
endif;

end;
```

# LongPathFromShortPath

Use the **LongPathFromShortPath** function to convert a short file name to its equivalent long file name.

For an explanation of long file names, see Long File Names.

## Syntax

```
LongPathFromShortPath ( svPath );
```

## Parameters

**Table 95** ▪ LongPathFromShortPath Parameters

| Parameter     | Description                                                            |
|---------------|------------------------------------------------------------------------|
| <b>svPath</b> | Specifies a short file name and returns its associated long file name. |

## Return Values

**Table 96** ▪ LongPathFromShortPath Return Values

| Return Value  | Description                                     |
|---------------|-------------------------------------------------|
| <b>0</b>      | Indicates that the function was successful.     |
| <b>&lt; 0</b> | Indicates that the function was not successful. |

## LongPathFromShortPath Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the functions LongPathToShortPath and
* LongPathFromShortPath.
*
* First, LongPathToShortPath is called to convert a long path
* to a short path. Then LongPathFromShortPath is called to
* convert the short path to a long path. The result of each
* is displayed in a message box.
*
\*-----*/

#define LONG_PATH "C:\\Program files"
#define TITLE "LongPathToShortPath & LongPathFromShortPath"
```

```

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_LongPathFromShortPath(HWND);

function ExFn_LongPathFromShortPath(hMSI)
    STRING svPath, szTitle, szMsg;
begin

    // Prompt user to enter a long path.
    szMsg = "Please select an existing long path:";
    AskPath (szMsg, LONG_PATH, svPath);

    // Display the long path.
    szMsg = "The long path is shown below: \n\n%s";
    sprintfBox (INFORMATION, TITLE, szMsg, svPath);

    //Convert the long path to a short path.
    if (LongPathToShortPath (svPath) < 0) then;
        MessageBox ("LongPathToShortPath failed.", SEVERE);
        abort;
    else
        // Display the short path.
        szMsg = "The short path is shown below: \n\n%s";
        sprintfBox (INFORMATION, TITLE, szMsg, svPath);
    endif;

    // Restore the long path from the short path.
    if (LongPathFromShortPath (svPath) < 0) then
        MessageBox ("LongPathFromShortPath failed.", SEVERE);
    else
        // Display the restored long path.
        szMsg = "The restored long path is shown below: \n\n%s";
        sprintfBox (INFORMATION, TITLE, szMsg, svPath);
    endif;

end;

```

## LongPathToQuote

The **LongPathToQuote** function places double quotation marks around a long file name or removes the double quotation marks from a long file name.

For an explanation of long file names, see Long File Names.

Add double quotation marks to long file names that contain spaces before passing the long file names to the command line. You must remove the double quotation marks from long file names before converting them to short file names using the [LongPathToShortPath](#) function. If you do not, the quoted long file name remains intact.

---

**Note** ▪ This function adds quotation marks only if there is a space character in the file name. For example, quotation marks are not added around C:\ThisismyApp because it is a long file name without a space.

## Syntax

LongPathToQuote ( svPath, nParameter );

## Parameters

**Table 97** ▪ LongPathToQuote Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svPath</b>     | Specifies a long file name and returns that name with or without quotation marks, depending on the value passed in nParameter.                                                                                                                                                                                                                                 |
| <b>nParameter</b> | <p>Specifies whether quotation marks are to be added to the long path or removed from the long path. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Quotation marks are added to the long path.</li> <li>• <b>FALSE</b>—Quotation marks are removed from the long path.</li> </ul> |

## Return Values

**Table 98** ▪ LongPathToQuote Return Values

| Return Value  | Description                                     |
|---------------|-------------------------------------------------|
| <b>0</b>      | Indicates that the function was successful.     |
| <b>&lt; 0</b> | Indicates that the function was not successful. |

## LongPathToQuote Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the LongPathToQuote function.
*
* This script calls LongPathToQuote to place double quotation
* marks around a long file name. The result is displayed in
* in a dialog. Then, LongPathToQuote is called again to
* remove the quotation marks and the result displayed in a

```

```

* dialog.
*
\*-----*/

// Define a constant for the base path (a long file name).
#define BASE_PATH "C:\\Program Files"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_LongPathToQuote(HWND);

function ExFn_LongPathToQuote(hMSI)
    STRING  svPath, szMainDirectory, szMsg;
begin

    // Set up parameter for call to LongPathToQuote.
    svPath = BASE_PATH;

    // Place double quotation marks around the long file name in svPath.
    if (LongPathToQuote (svPath, TRUE) < 0) then
        MessageBox ("First call to LongPathToQuote failed.", SEVERE);
        abort;
    endif;

    // Display the quoted long file name in svPath.
    szMsg = "The quoted long file name:\n\n" + svPath;
    MessageBox (szMsg, INFORMATION);

    // Remove the quotation marks from the long file name in svPath.
    if (LongPathToQuote (svPath, FALSE) < 0) then
        MessageBox ("Second call to LongPathToQuote failed.", SEVERE);
        abort;
    endif;

    // Display the long file name with quotation marks removed.
    szMsg = "The unquoted long file name is shown below: \n\n" + svPath;

    MessageBox (szMsg, INFORMATION);

end;

```

## LongPathToShortPath

The **LongPathToShortPath** function converts a long file name to its equivalent short file name. The parameter **svPath** can be an absolute path or a relative path, and it may include a file name; but the folder or file it specifies must exist on the target system.

For an explanation of long file names, see Long File Names.

### Syntax

```
LongPathToShortPath ( svPath );
```

## Parameters

**Table 99** ▪ LongPathToShortPath Parameters

| Parameter     | Description                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svPath</b> | Specifies a long file name and returns its associated short file name.                                                                                                               |
|               |  <p><b>Note</b> ▪ <i>LongPathToShortPath removes trailing backslashes from long file names.</i></p> |

## Return Values

**Table 100** ▪ LongPathToShortPath Return Values

| Return Value  | Description                                     |
|---------------|-------------------------------------------------|
| <b>0</b>      | Indicates that the function was successful.     |
| <b>&lt; 0</b> | Indicates that the function was not successful. |

## Additional Information

Since **LongPathToShortPath** can succeed only if the specified folder or file can be found on the target system, you may need to set the current folder before specifying a relative path. For example, if svPath contains the relative path InstallShield, which exists in the folder C:\Program Files, the setup is not able to find it unless the current folder is C:\Program Files. Use the [ChangeDirectory](#) function to change the current folder when necessary before calling **LongPathToShortPath** so that the target folder or path can be found.

## LongPathToShortPath Example

**Note** ▪ *To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.*

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the functions LongPathToShortPath and
* LongPathFromShortPath.
*
* First, LongPathToShortPath is called to convert a long path
* to a short path. Then LongPathFromShortPath is called to
* convert the short path to a long path. The result of each
* is displayed in a message box.
*
\*-----*/
```

```

#define LONG_PATH "C:\\Program Files"
#define TITLE "LongPathToShortPath & LongPathFromShortPath"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_LongPathToShortPath(HWND);

function ExFn_LongPathToShortPath(hMSI)
    STRING svPath, szTitle, szMsg;
begin

    // Prompt user to enter a long path.
    szMsg = "Please select an existing long path:";
    AskPath (szMsg, LONG_PATH, svPath);

    // Display the long path.
    szMsg = "The long path is shown below: \\n\\n%s";
    sprintfBox (INFORMATION, TITLE, szMsg, svPath);

    //Convert the long path to a short path.
    if (LongPathToShortPath (svPath) < 0) then;
        MessageBox ("LongPathToShortPath failed.", SEVERE);
        abort;
    else
        // Display the short path.
        szMsg = "The short path is shown below: \\n\\n%s";
        sprintfBox (INFORMATION, TITLE, szMsg, svPath);
    endif;

    // Restore the long path from the short path.
    if (LongPathFromShortPath (svPath) < 0) then
        MessageBox ("LongPathFromShortPath failed.", SEVERE);
    else
        // Display the restored long path.
        szMsg = "The restored long path is shown below: \\n\\n%s";
        sprintfBox (INFORMATION, TITLE, szMsg, svPath);
    endif;

end;

```

## LOWORD

The **LOWORD** function extracts the low-order word (two bytes) from the 32-bit integer value specified by lValue.

### Syntax

```
LOWORD ( lValue );
```

## Parameters

**Table 101** ▪ LOWORD Parameters

| Parameter     | Description                                                                      |
|---------------|----------------------------------------------------------------------------------|
| <b>IValue</b> | Specifies the 32-bit integer from which you want to extract the lower two bytes. |

## Return Values

This function returns the low-order word (lower two bytes) of the integer.

## LOWORD Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates HIWORD and LOWORD.
 *
 * This example script shows how to use HIWORD and LOWORD to
 * to get the low-order word and the high-order word from a value.
 \*-----*/

#define TITLE_TEXT "LOWORD/HIWORD Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_LOWORD(HWND);

function ExFn_LOWORD(hMSI)
    STRING  szMsg;
    NUMBER  nData, nLOWORD, nHIWORD;
begin

    nData = 305419896; // hex value: 12345678
    // Get the low-order word, 22136 (hex value: 5678).

    nLOWORD = LOWORD (nData);

    // Get the high-order word, 4660 (hex value: 1234).
    nHIWORD = HIWORD (nData);

    // Display the results.
    szMsg = "LOWORD: %ld\nHIWORD: %ld";
    sprintfBox (INFORMATION, TITLE_TEXT, szMsg, nLOWORD, nHIWORD);

end;
```

# MaintenanceStart

The **MaintenanceStart** function creates a registry key and associated values that are used during initialization for maintenance or uninstallation and that provide information about the application to Add or Remove Programs. This function is called by the default code for the OnMoveData event handler.

**Note** ▪ The InstallScript engine currently does not support writing or reading Add or Remove Programs information for a product in the 64-bit part of the registry. Therefore, using the REGDB\_OPTION\_WOW64\_64KEY option with the REGDB\_OPTIONS system variable is not supported for this registry function. Enabling the REGDB\_OPTION\_WOW64\_64KEY option has no effect on where registry entries are created by this function.

**MaintenanceStart** creates the following values under the application uninstallation registry key:

**Table 102** ▪ Application Uninstallation Registry Key Values

| Value Name             | Value Data                                                                                                                   |
|------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Comments</b>        | The value of the system variable IFX_PRODUCT_COMMENTS, if non-null; otherwise, the function does not create an entry.        |
| <b>Contact</b>         | The value of the system variable IFX_PRODUCT_SUPPORT_CONTACT, if non-null; otherwise, the function does not create an entry. |
| <b>DisplayIcon</b>     | The value of the system variable IFX_PRODUCT_ICON, if non-null; otherwise, the function does not create an entry.            |
| <b>DisplayName</b>     | The value of the system variable IFX_PRODUCT_NAME, if non-null; otherwise, the function does not create an entry.            |
| <b>DisplayVersion</b>  | The value of the system variable IFX_PRODUCT_VERSION.                                                                        |
| <b>HelpLink</b>        | The value of the system variable IFX_PRODUCT_SUPPORT_URL, if non-null; otherwise, the function does not create an entry.     |
| <b>HelpTelephone</b>   | The value of the system variable IFX_PRODUCT_SUPPORT_PHONE, if non-null; otherwise, the function does not create an entry.   |
| <b>InstallDate</b>     | The date on which the installation is run, in the format <code>yyyymmdd</code> .                                             |
| <b>InstallLocation</b> | The value of the system variable TARGETDIR.                                                                                  |
| <b>InstallSource</b>   | The value of the system variable SRCDIR.                                                                                     |
| <b>Language</b>        | The value of the system variable SELECTED_LANGUAGE.                                                                          |
| <b>LogFile</b>         | <DISK1TARGET>\Setup.ilg                                                                                                      |
| <b>LogMode</b>         | The value of the system variable MAINT_OPTION.                                                                               |

**Table 102** ■ Application Uninstallation Registry Key Values (cont.)

| Value Name             | Value Data                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>ModifyPath</b>      | <p>The value of the system variable <code>UNINSTALL_STRING</code> if <code>ADDREMOVE_HIDECHANGEOPTION</code> is FALSE and either of the following two conditions is true:</p> <ul style="list-style-type: none"> <li>• <code>ADDREMOVE_HIDEREMOVEOPTION</code> is non-zero</li> <li>• <code>ADDREMOVE_HIDEREMOVEOPTION</code> and <code>ADDREMOVE_COMBINEDBUTTON</code> are both FALSE</li> </ul> <p>Otherwise, the function does not create an entry.</p>                                                                   |
| <b>NoModify</b>        | The value of the system variable <code>ADDREMOVE_HIDEREMOVEOPTION</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>NoRemove</b>        | The value of the system variable <code>ADDREMOVE_HIDEREMOVEOPTION</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>NoRepair</b>        | 1 if either <code>ADDREMOVE_HIDECHANGEOPTION</code> or <code>ADDREMOVE_HIDEREMOVEOPTION</code> is non-zero; otherwise, the function does not create an entry.                                                                                                                                                                                                                                                                                                                                                                |
| <b>ProductGuid</b>     | The value of the system variable <code>PRODUCT_GUID</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ProductId</b>       | The value of the system variable <code>IFX_PRODUCT_REGISTEREDSERIALNUM</code> , if non-null; otherwise, the function does not create an entry.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Publisher</b>       | The value of the system variable <code>IFX_COMPANY_NAME</code> , if non-null; otherwise, the function does not create an entry.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Readme</b>          | The value of the system variable <code>IFX_PRODUCT_README</code> , if non-null; otherwise, the function does not create an entry.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>RegCompany</b>      | The value of the system variable <code>IFX_PRODUCT_REGISTEREDCOMPANY</code> , if non-null; otherwise, the function does not create an entry.                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>RegOwner</b>        | The value of the system variable <code>IFX_PRODUCT_REGISTEREDOWNER</code> , if non-null; otherwise, the function does not create an entry.                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>SystemComponent</b> | 1 if the system variable <code>ADDREMOVE_SYSTEMCOMPONENT</code> is non-zero; otherwise, the function does not create an entry.                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>UninstallString</b> | <p>The value of the system variable <code>UNINSTALL_STRING</code>. Additionally, the value of the system variable <code>ADDREMOVE_STRING_REMOVEONLY</code> is appended to this registry data if <code>ADDREMOVE_HIDECHANGEOPTION</code> is FALSE and either of the following two conditions is true:</p> <ul style="list-style-type: none"> <li>• <code>ADDREMOVE_HIDECHANGEOPTION</code> is non-zero</li> <li>• <code>ADDREMOVE_HIDECHANGEOPTION</code> and <code>ADDREMOVE_COMBINEDBUTTON</code> are both FALSE</li> </ul> |

**Table 102** ▪ Application Uninstallation Registry Key Values (cont.)

| Value Name           | Value Data                                                                                                                               |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>URLInfoAbout</b>  | The value of the system variable <a href="#">IFX_PRODUCT_URL</a> , if non-null; otherwise, the function does not create an entry.        |
| <b>URLUpdateInfo</b> | The value of the system variable <a href="#">IFX_PRODUCT_UPDATE_URL</a> , if non-null; otherwise, the function does not create an entry. |
| <b>Version</b>       | The packed DWORD equivalent of the data in the DisplayVersion value.                                                                     |
| <b>VersionMajor</b>  | The first byte of the data in the Version value.                                                                                         |
| <b>VersionMinor</b>  | The second byte of the data in the Version value.                                                                                        |

## Syntax

```
MaintenanceStart ( );
```

## Parameters

None

## Return Values

**Table 103** ▪ MaintenanceStart Return Values

| Return Value  | Description                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully created the registry key and its associated values.                                                                                                                                                                             |
| <b>&lt; 0</b> | Indicates that the function was unable to create the registry key and its associated values.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

InstallScript installations always create VersionMajor and VersionMinor registry values in the Uninstall key. This applies to new installations that are created in InstallShield 2022, as well as installations that are upgraded from InstallShield 2009 or earlier. Previously, in InstallShield 2009 and earlier, the names of the values that InstallScript installations created were MajorVersion and MinorVersion; these are no longer created.

When the **MaintenanceStart** function is called, it creates the VersionMajor and VersionMinor value names in the registry. By default, it also deletes the MajorVersion and MinorVersion value names if they exist. If you do not want the MajorVersion and MinorVersion value names to be deleted from target systems, you can use the [REGDB\\_OPTIONS](#) option called REGDB\_OPTION\_NO\_DELETE\_OLD\_MAJMIN\_VERSION. If you want to continue using only the MajorVersion and MinorVersion value names, you must delete VersionMajor and VersionMinor after **MaintenanceStart** returns.

# MediaGetData

---

**Project** ▪ This information applies to InstallScript projects.

The **MediaGetData** function retrieves information about a file media library.

**MediaGetData** calls MediaGetDataEx(szMediaSource, nInfo, nvResult, svResult, FALSE). For information on parameters and return values for **MediaGetData**, see [MediaGetDataEx](#).

## Syntax

```
MediaGetData ( szMediaSource, nInfo, nvResult, svResult );
```

# MediaGetDataEx

---

**Project** ▪ This information applies to InstallScript projects.

The **MediaGetDataEx** function retrieves information about a file media library, including media information that is stored in the project's string entries.

## Syntax

```
MediaGetDataEx ( szMediaSource, nInfo, nvResult, svResult, bCheckStringTable );
```

## Parameters

**Table 104** ▪ MediaGetDataEx Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMediaSource</b> | Specifies the name of the file media library whose information is to be retrieved; typically, the value of this argument is the system variable MEDIA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>nInfo</b>         | <p>Specifies the type of information to retrieve. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>MEDIA_FIELD_ADDREMOVE_NOMODIFY</b>—Retrieves the setting that you specified in the Disable Change Button setting in the General Information view. The value is returned in nvResult; 0 corresponds to No and 1 corresponds to Yes.</li> <li>● <b>MEDIA_FIELD_ADDREMOVE_NOREMOVE</b>—Retrieves the setting that you specified in the Disable Remove Button setting in the General Information view. The value is returned in nvResult; 0 corresponds to No and 1 corresponds to Yes.</li> <li>● <b>MEDIA_FIELD_COMPANY_NAME</b>—Retrieves the company name that you specified in the General Information view. The company name is returned in svResult.</li> <li>● <b>MEDIA_FIELD_MEDIA_FLAGS</b>—Retrieves the format of the specified file media library. The number returned in nvResult includes any applicable values from among the following bit flags: <ul style="list-style-type: none"> <li>MEDIA_FLAG_FORMAT_DIFFERENTIAL: Indicates a differential file media library.</li> <li>MEDIA_FLAG_UPDATESUPPORTED: Indicates an update enabled file media library. This flag is always set.</li> </ul> </li> <li>● <b>MEDIA_FIELD_PREVIOUS_VERSIONS</b>—Retrieves the version information that you specified in the Supported Version(s) property of the Releases view or in the Update panel in the Release Wizard. The version information is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_COMMENTS</b>—Retrieves the comments that you specified in the ARP Comments setting in the General Information view. The value is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_EXE</b>—Retrieves the executable name that you specified in the General Information view. The executable name is returned in svResult.</li> </ul> |

**Table 104** ▪ MediaGetDataEx Parameters (cont.)

| Parameter                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nInfo (cont.)</b>     | <ul style="list-style-type: none"> <li>● <b>MEDIA_FIELD_PRODUCT_ICON</b>—Retrieves the display icon that you specified in the Display Icon setting in the General Information view. The value is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_NAME</b>—Retrieves the product name that you specified in the General Information view. The product name is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_README</b>—Retrieves the readme file that you specified in the Read Me setting in the General Information view. The value is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_SUPPORT_CONTACT</b>—Retrieves the support contact that you specified in the Support Contact setting in the General Information view. The value is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_SUPPORT_PHONE</b>—Retrieves the support phone number that you specified in the Support Phone Number setting in the General Information view. The value is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_SUPPORT_URL</b>—Retrieves the support URL that you specified in the Support URL setting in the General Information view. The value is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_UPDATE_URL</b>—Retrieves the product update URL that you specified in the Product Update URL setting in the General Information view. The value is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_URL</b>—Retrieves the publisher/product URL that you specified in the Publisher/Product URL setting in the General Information view. The value is returned in svResult.</li> <li>● <b>MEDIA_FIELD_PRODUCT_VERSION</b>—Retrieves the version information that you specified in the General Information view. The version information is returned in svResult.</li> <li>● <b>MEDIA_FIELD_TARGETDIR</b>—Retrieves the value of TARGETDIR that you specified in the General Information view.</li> </ul> |
| <b>bCheckStringTable</b> | Specifies whether svResult returns the string that you entered in InstallShield (FALSE) or, if the string that you entered in InstallShield is a string identifier, the string value that is associated with that identifier (TRUE). If bCheckStringTable is TRUE but the string that you entered in InstallShield is not a string identifier, svResult returns the string that you entered in InstallShield.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Return Values

**Table 105** ▪ MediaGetDataEx Return Values

| Return Value | Description                                                    |
|--------------|----------------------------------------------------------------|
| 0            | MediaGetData successfully retrieved the requested information. |
| < 0          | MediaGetData failed to retrieve the requested information.     |

## MessageBeep

The **MessageBeep** function plays the default system sound.

**Tip** ▪ You can also give audio cues by calling *PlayMMedia* to play an audio file.

## Syntax

```
MessageBeep ( nReserved );
```

## Parameters

**Table 106** ▪ MessageBeep Parameters

| Parameter | Description                                             |
|-----------|---------------------------------------------------------|
| nReserved | Pass zero in this parameter. No other value is allowed. |

## Return Values

This function has no return values.

## MessageBeep Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the MessageBeep function.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_MessageBeep(HWND);
```

```
function ExFn_MessageBeep(hMSI)
begin

    // Play the default system sound.
    MessageBeep (0);

    // Display a message box.
    MessageBox ("Please listen for a sound.", INFORMATION);

    // Play the default system sound.
    MessageBeep (0);

end;
```

## MessageBox

**Project** • This information applies to the following project types:

- Basic MSI
- InstallScript
- InstallScript MSI

The **MessageBox** function presents a dialog that contains a message, an icon that indicates the nature of the message (information, warning, or severe), and an OK button. The default title depends on the value of `nType`, which also indicates the icon type. For example, if you pass `INFORMATION` in `nType`, the title **Information** appears in the title bar. The titles are blank by default, unless you set them by calling [SetDialogTitle](#) before calling **MessageBox**. If the titles are blank, the title bar text for message box is the product name (from `IFX_SETUP_TITLE`).

This function uses the Microsoft Windows API **MessageBox**. The operating environment, not the installation, determines the size and location of the message box. The operating environment also generates the text for the OK button in the local language (the language that the operating system is running under). You cannot change the text on this button. For more information regarding the use of Windows **MessageBox** types, consult the description of the **MessageBox** Windows API function in the appropriate Windows SDK.

Note the following when using Windows message box constants:

- Some Windows **MessageBox** type constants are predefined in the `ISRTWindows.h` file that is provided in the *InstallShield Program Files Folder\Script\Isrt\Include* folder. This file is automatically included in your installation when you include `Ifx.h` in your script. You do not need to redefine any constants that are defined in `ISRTWindows.h`; doing so will result in a compiler warning. To determine which constants are predefined, refer to the `ISRTWindows.h` file.
- To use constants that are not defined in `ISRTWindows.h`, you must define them (using `#define`) in the declaration block of your installation script. You cannot simply include the `Windows.h` file that is usually part of a C++ program. The values that you need to assign to the undefined constants can generally be found in an include file that is provided with the appropriate Windows SDK or development tool. (For Microsoft Visual C++, most constants can be found in the `Winuser.h` file, which is located in the *InstallShield Program Files Folder\Script\Resource* folder.)

- Windows and InstallShield message box constants cannot be used together in an installation. If an InstallShield message box constant is combined with a Windows message box constant using the OR operator (`|`), the Windows message box constant is ignored.
- Some Windows message box styles are not supported on some Windows platforms. To determine whether a particular style is supported on the operating systems that are targeted by the installation, consult the appropriate Windows SDK.
- When a Windows message box style is used by the **MessageBox** function, the caption (title) of the message box is **Install**. If you need to display a different caption, use the **MessageBoxEx** function.

## Syntax

```
MessageBox ( szMsg, nType );
```

## Parameters

**Table 107** ▪ MessageBox Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b> | Specifies the message to display. InstallShield does not automatically break the text of the message into separate lines to fit in the message box. If the message is too long for one line, insert a line break by embedding newline escape characters ( <code>\n</code> ) at appropriate places in the string.                                                                                                                                                       |
| <b>nType</b> | <p>Specifies the type of message box to create and the type of icon to display in the message box. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• INFORMATION</li> <li>• WARNING</li> <li>• SEVERE</li> </ul> <p>Any Windows API MessageBox type can also be specified in this parameter. Multiple styles can be combined logically using the OR operator to produce the required MessageBox type.</p> |

## Return Values

The return value is not significant unless you are using standard Microsoft Windows message box styles. If you are using these styles, the return value is the same as the return value from the MessageBox API functions.

## Additional Information

The dialog that is displayed by the MessageBox function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## MessageBox Example

**Project** ▪ This information applies to the following project types:

- Basic MSI
- InstallScript
- InstallScript MSI

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the MessageBox function.
 *
 * This script displays three message boxes, each with a
 * different message and icon.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_MessageBox(HWND);

function ExFn_MessageBox(hMSI)
    STRING szMsg;
begin

    // Display a message box that shows the information icon.
    szMsg = "This will install Example Program.";
    MessageBox (szMsg, INFORMATION);

    // Display a message box that shows the warning icon.
    szMsg = "Installing this version will replace previous one.";
    MessageBox (szMsg, WARNING);

    // Display a message box that shows the severe icon.
    szMsg = "Cannot install this application on floppy drives.";
    MessageBox (szMsg, SEVERE);

end;
```

## MessageBoxEx

**Project** ▪ This information applies to the following project types:

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

The **MessageBoxEx** function presents a dialog that contains a message, an icon that indicates the nature of the message (information, warning, or severe), and an OK button. The title is set by `szCaption`.

This function uses the Microsoft Windows API `MessageBox`. The operating environment, not `InstallShield`, determines the size and location of the message box. The operating environment also generates the text for the OK button in the local language (the language that the operating system is running under). You cannot change the text in this button. For more information regarding the use of Windows `MessageBox` types, consult the description of the `MessageBox` Windows API function in the appropriate Windows SDK.

Note the following when using Windows message box constants:

- Some Windows **MessageBox** type constants are predefined in the `ISRTWindows.h` file that is provided in the *InstallShield Program Files Folder\Script\Isrt\Include* folder. This file is automatically included in your installation when you include `Ifx.h` in your script. You do not need to redefine any constants that are defined in `ISRTWindows.h`; doing so will result in a compiler warning. To determine which constants are predefined, refer to the `ISRTWindows.h` file.
- To use constants that are not defined in `ISRTWindows.h`, you must define them (using `#define`) in the declaration block of your installation script. You cannot simply include the `Windows.h` file that is usually part of a C++ program. The values that you need to assign to the undefined constants can generally be found in an include file that is provided with the appropriate Windows SDK or development tool. (For Microsoft Visual C++, most constants can be found in the `Winuser.h` file, which is located in the *InstallShield Program Files Folder\Script\Resource* folder.)
- Windows and `InstallShield` message box constants cannot be used together in an installation. If an `InstallShield` message box constant is combined with a Windows message box constant using the OR operator, the Windows message box constant will be ignored.
- Some Windows message box styles are not supported on some Windows platforms. To determine whether a particular style is supported on the operating system(s) targeted by the installation, consult the appropriate Windows SDK.

## Syntax

```
MessageBoxEx( szMsg, szCaption, nType );
```

## Parameters

**Table 108** ▪ MessageBoxEx Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b>     | Specifies the message to display. InstallShield does not automatically break the text of the message into separate lines to fit in the message box. If the message is too long for one line, insert a line break by embedding newline escape characters ( \n ) at appropriate places in the string.                                                                                                                                                                                                        |
| <b>szCaption</b> | Specifies the title to display. If you pass a null string ("" ) in this parameter, the value of the system variable <b>IFX_SETUP_TITLE</b> is used as the dialog title.                                                                                                                                                                                                                                                                                                                                    |
| <b>nType</b>     | <p>Specifies the type of message box to create and the type of icon to display in the message box. Pass one of the following predefined constants in this parameter (Explorer shell icons are shown):</p> <ul style="list-style-type: none"> <li>● INFORMATION</li> <li>● WARNING</li> <li>● SEVERE</li> </ul> <p>Any Windows API MessageBox type can also be specified in this parameter. Multiple styles can be combined logically with the OR operator ( ) to produce the required MessageBox type.</p> |

## Return Values

The return value is not significant unless you are using standard Microsoft Windows message box styles. If you are using these styles, the return value is the same as the return value from the MessageBox API functions.

## Additional Information

The message box that is displayed by the MessageBoxEx function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

# NumToStr

The **NumToStr** function converts a number to a string.

## Syntax

```
NumToStr ( svString, nValue );
```

## Parameters

**Table 109** ▪ NumToStr Parameters

| Parameter       | Description                                  |
|-----------------|----------------------------------------------|
| <b>svString</b> | Returns the string equivalent of nValue.     |
| <b>nValue</b>   | Specifies the number to convert to a string. |

## Return Values

**Table 110** ▪ NumToStr

| Return Value  | Description                                                                |
|---------------|----------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully converted the number to a string. |
| <b>&lt; 0</b> | Indicates that the function failed to convert the number to a string.      |

## NumToStr Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the NumToStr function
 *
 * This script calls NumToStr convert the numeric value of free
 * disk space available on the system to a string so that it
 * can be displayed by the MessageBox function.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_NumToStr(HWND);

function ExFn_NumToStr(hMSI)
    STRING  svString;
    NUMBER  nSpace, nResult;
begin

    // Get the amount of free space on drive C.
    nSpace = GetDiskSpace ("C:");
```

```

// Convert the number to a string.
nResult = NumToStr (svString, nSpace);

if (nResult < 0) then
    MessageBox ("NumToStr failed.", SEVERE);
else
    // Display the amount of free space on drive C.
    MessageBox (svString + " bytes free on drive C.", INFORMATION);
endif;

end;

```

## OpenFile

The **OpenFile** function opens an existing text file or binary file. Before you open the file you must set the file mode by calling **OpenFileMode**.

**Tip** ▪ Note the following:

- After you open a text file, call *GetLine* and *WriteLine* to read from and write to the file. When you finish reading from or writing to a file with *GetLine* or *WriteLine*, you must close the file using the *CloseFile* function.
- After you open a binary file, call *ReadBytes* and *WriteBytes* to read from and write to the file.
- You can use *SeekBytes* to position the file pointer before writing to a binary file.
- You can also search, read from, and write to text files using the *FileGrep*, *FileInsertLine*, and *FileDeleteLine* functions. However, these functions do not require you to open or close the files (this is handled internally).
- Use *CreateFile* to create a file. *CreateFile* leaves the new file open in append mode (text files) or read/write mode (binary files).

### Syntax

```
OpenFile ( nvFileHandle, szPath, szFileName );
```

## Parameters

**Table 111** ▪ OpenFile Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvFileHandle</b> | Returns the file handle of the file that was opened. Use this handle to identify the file when you call other file-related InstallScript functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>szPath</b>       | Specifies the path—which may include a drive designation—of the file you want to open. You can specify a valid Uniform Resource Locator (URL) in this parameter, after setting the file mode to <code>FILE_MODE_NORMAL</code> or <code>FILE_MODE_BINARYREADONLY</code> (by calling <code>OpenFileMode</code> ). If you pass a CGI or ASP request (for example, "http://www.mydomain.net/login.asp?name=Me&pwd=wow"), the response is sent to memory and can be read by <code>ReadBytes</code> . To check the validity of a URL, call <code>Is(VALID_PATH, szURL)</code> . If you pass a null string ("") in this parameter, the function fails. |
| <b>szFileName</b>   | Specifies the unqualified name—that is, without a drive designation or path—of the file you want to open. If you pass a null string ("") in this parameter, the function fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Return Values

**Table 112** ▪ OpenFile Return Values

| Return Value  | Description                                               |
|---------------|-----------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully opened the file. |
| <b>&lt; 0</b> | Indicates that the function was unable to open the file.  |

## OpenFile Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the OpenFile and CloseFile functions.
 *
 * OpenFile is called to open a file, which is then read into
 * a list. The file is then closed and the list is displayed.
 *
 * Note: Before running this script, set the preprocessor
 *       constants so that they reference an existing file
 *       in an existing directory.
 *
\*-----*/

```

```

#define EXAMPLE_FILE "Readme.txt"
#define EXAMPLE_DIR "C:\\Windows"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_OpenFile(HWND);

function ExFn_OpenFile(hMSI)
    STRING  svLine;
    NUMBER  nvFileHandle;
    LIST    listID;
begin

    // Set the file mode to normal.
    OpenFileMode (FILE_MODE_NORMAL);

    // Open the text file.
    if (OpenFile (nvFileHandle, EXAMPLE_DIR, EXAMPLE_FILE) < 0) then
        MessageBox ("OpenFile failed.", SEVERE);
        abort;
    endif;

    // Create an empty string list.
    listID = ListCreate (STRINGLIST);

    // Read lines from the text file into the string list.
    while GetLine (nvFileHandle, svLine) = 0
        ListAddString (listID, svLine, AFTER);
    endwhile;

    // Close the file.
    if (CloseFile (nvFileHandle) < 0) then
        MessageBox ("CloseFile failed.", SEVERE);
    endif;

    // Display the text that was read from the file.
    SdShowInfoList ("", "", listID);

end;

```

## OpenFileMode

The **OpenFileMode** function sets the mode of the file you want to open or create. The argument you pass as the parameter `nMode` sets the file mode to one of the following:

- ANSI or Unicode text file in append mode.
- ANSI or Unicode text file in read-only mode.
- Binary file in read/write mode.
- Binary file in read-only mode.

After you set the file mode, call [OpenFile](#) to open an existing file or [CreateFile](#) to create and open a new file.

## Syntax

```
OpenFileMode ( nMode );
```

## Parameters

**Table 113** ▪ OpenFileMode Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nMode</b> | <p>Specifies which mode to use to open a file. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FILE_MODE_APPEND</b>—This constant allows a text file to be opened or created in append mode. When a file is opened in append mode using <b>OpenFile</b>, the file pointer is at the end of the file. You can use the <b>WriteLine</b> function to append lines to the end of the file. Files created using <b>CreateFile</b> are new (empty), so lines appended to the files are written at the beginning of the files. Note that if you open a file in append mode, the <b>GetLine</b> function will fail if you call it because the file pointer is at the end of the file.</li> <li>● <b>FILE_MODE_APPEND_UNICODE</b>—Indicates that <b>CreateFile</b> should create new files as Unicode files, instead of the default of ANSI. This option does not affect how existing files are opened. Existing files are always opened and saved in the existing format. To convert a file from one type to another, use the <b>ListReadFromFile</b> and <b>ListWriteToFileEx</b> with the appropriate <b>nOptions</b>.</li> <li>● <b>FILE_MODE_NORMAL</b>—This constant allows a text file to be opened in read-only mode. When a file is opened in read-only mode using <b>OpenFile</b>, the file pointer is at the beginning of the file. You can use the <b>GetLine</b> function to read from the file. Files created using <b>CreateFile</b> when <b>FILE_MODE_NORMAL</b> is in effect will actually be created in <b>FILE_MODE_APPEND</b> mode.</li> <li>● <b>FILE_MODE_BINARY</b>—This constant allows a binary file to be opened and created in read/write mode. When you open or create a file in binary mode with <b>OpenFile</b> or <b>CreateFile</b>, you can call <b>ReadBytes</b> to read from the file and <b>WriteBytes</b> to write to the file. Writing to a binary file begins at the current file pointer position, which for a newly opened or created file is position 0—the beginning of the file. If you want to append to an existing binary file opened using <b>OpenFile</b>, you must use <b>SeekBytes</b> to position the file pointer before writing. To open a file on a CD-ROM or on a read-only drive, call <b>OpenFileMode</b> to set the file mode to read-only (<b>FILE_MODE_BINARYREADONLY</b>).</li> <li>● <b>FILE_MODE_BINARYREADONLY</b>—This constant is just like the constant <b>FILE_MODE_BINARY</b>, except that it opens the binary file in read-only mode. When opening a binary file on CD-ROM or read-only drives, use this constant to open a binary file. <b>FILE_MODE_BINARY</b> will fail opening binary files on CD-ROM or read-only drives.</li> </ul> |

## Return Values

**Table 114** ▪ OpenFileMode Return Values

| Return Value | Description                                                 |
|--------------|-------------------------------------------------------------|
| <b>0</b>     | Indicates that the function successfully set the file mode. |

**Table 114** ▪ OpenFileMode Return Values (cont.)

| Return Value | Description                                                  |
|--------------|--------------------------------------------------------------|
| < 0          | Indicates that the function was unable to set the file mode. |

## OpenFileMode Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the OpenFileMode function.
 *
 * This script opens a text file in read-only (FILE_MODE_NORMAL)
 * mode. It then retrieves and displays the first line from
 * the file.
 *
 * Next, it opens a file in binary mode, positions the file
 * pointer at the 15th byte and reads 28 bytes from the file.
 *
 * Note: In order for this script to run correctly, you must set
 *       the preprocessor constants so that they reference
 *       existing files in an existing directory.
 *
\*-----*/

#define EXAMPLE_DIR      "C:\\\"
#define EXAMPLE_TEXT_FILE "ISExempl.txt"
#define EXAMPLE_BIN_FILE  "ISExempl.bin"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_OpenFileMode(HWND);

function ExFn_OpenFileMode(hMSI)
    STRING svLine, svString;
    NUMBER nvFileHandle;
begin

    // Set the file mode to normal.
    OpenFileMode (FILE_MODE_NORMAL);

    // Open the file.
    if (OpenFile (nvFileHandle, EXAMPLE_DIR, EXAMPLE_TEXT_FILE) < 0) then
        MessageBox ("OpenFile failed.", SEVERE);
        abort;
    endif;

    // Get the first line of the text file.
    GetLine (nvFileHandle, svLine);

```

```

// Display the line.
MessageBox (svLine, INFORMATION);

// Close the file.
CloseFile (nvFileHandle);

// Set the file mode to binary read/write.
OpenFileMode (FILE_MODE_BINARY);

// Open the file.
if (OpenFile (nvFileHandle, EXAMPLE_DIR, EXAMPLE_BIN_FILE) < 0) then
    MessageBox ("OpenFile failed.", SEVERE);
else
    // Move the file pointer to byte 15.
    SeekBytes (nvFileHandle, 15, FILE_BIN_START);

    // Read 28 bytes from the binary file into svString.
    if (ReadBytes (nvFileHandle, svString, 0, 28) < 0) then
        MessageBox ("ReadBytes failed.", SEVERE);
    else
        // Display the string.
        MessageBox (svString, INFORMATION);
    endif;

    // Close the binary file.
    CloseFile (nvFileHandle);
endif;

end;

```

## ParsePath

The **ParsePath** function retrieves the specified part of an existing path. The function works with any valid path, including short paths, long paths, and UNC paths that may or may not include a specific file name. These are some sample paths that can be parsed with this function.

- \Path1\Path2\Filename.exe
- FileName
- Filename.exe
- \Path1\Path2\Filename
- D:
- D:\
- \\Server Name\Share Name\Share Directory
- Any other legal DOS path

### Syntax

```
ParsePath ( svReturnString, szPath, nOperation );
```

## Parameters

**Table 115** ▪ ParsePath Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svReturnString</b> | Returns the part of the path in szPath that is specified by nOperation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>szPath</b>         | Specifies the path to parse. When specifying a path that does not include a file name, you must append a backslash to the end of the path before passing it to ParsePath; otherwise the last part of the path will be interpreted as a file name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>nOperation</b>     | <p>Specifies which element of the path to return. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>DIRECTORY</b>—Indicates that the path minus the disk drive letter and file name should be returned in svReturnString. When this option is used with a UNC path, ParsePath returns the path without the server and shared device name, and without the file name if one was specified. For example, the UNC path \\TheServer\TheSharedDevice\TheApp\TheFile.exe is returned in svReturnString as \TheApp\.</li> <li>● <b>DISK</b>—Indicates that the disk drive designation (drive letter followed by a colon) should be returned in svReturnString. When this option is used with a UNC path, ParsePath returns the server and shared device name. For example, the UNC path \\TheServer\TheSharedDevice\TheApp\TheFile.exe is returned in svReturnString as \\TheServer\TheSharedDevice.</li> <li>● <b>EXTENSION_ONLY</b>—Indicates that the file extension should be returned in svReturnString. It does not include the period.</li> <li>● <b>FILENAME</b>—Indicates that the complete file name (that is, with its file extension) should be returned in svReturnString.</li> <li>● <b>FILENAME_ONLY</b>—Indicates that the file name only (that is, without its file extension) should be returned in svReturnString.</li> <li>● <b>PATH</b>—Indicates that the path minus the file name should be returned in svReturnString. This option differs from DIRECTORY in that the drive designation (if specified in szPath) is included in the returned path. When szPath specifies a UNC path the server and shared device name are included in the returned path. For example, the UNC path \\TheServer\TheSharedDevice\TheApp\TheFile.exe is returned in svReturnString as \\TheServer\TheSharedDevice\TheApp\.</li> </ul> |

## Return Values

**Table 116** ▪ ParsePath Return Values

| Return Value  | Description                                                      |
|---------------|------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully parsed the path string. |
| <b>&lt; 0</b> | Indicates that the function was unable to parse the path string. |

## ParsePath Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ParsePath function.
*
* The ParsePath is called six times to retrieve various
* information from a fully-qualified file name.
*
\*-----*/

#define EXAMPLE_PATH "C:\\Windows\\Readme.txt"
#define TITLE_TEXT  "ParsePath example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ParsePath(HWND);

function ExFn_ParsePath(hMSI)
    STRING szMsg, svReturnString;
begin

    // Get the disk letter from the path.
    if (ParsePath (svReturnString, EXAMPLE_PATH, DISK) < 0) then
        MessageBox ("ParsePath failed", SEVERE);
    else
        szMsg = "nOperation = DISK\\n\\nParsed Path: %s";
        sprintfBox (INFORMATION, TITLE_TEXT , szMsg, svReturnString);
    endif;

    // Get the full path.
    szMsg = "nOperation = PATH\\n\\nParsed Path: %s";

    if (ParsePath (svReturnString, EXAMPLE_PATH, PATH) < 0) then
        MessageBox ("ParsePath failed", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svReturnString);
    endif;

    // Get the directory name.
    if (ParsePath (svReturnString, EXAMPLE_PATH, DIRECTORY) < 0) then
        MessageBox ("ParsePath failed", SEVERE);
    else
        szMsg = "nOperation = DIRECTORY\\n\\nParsed Path: %s";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svReturnString);
    endif;

    // Get the file name and extension.
    if (ParsePath (svReturnString, EXAMPLE_PATH, FILENAME) < 0) then
        MessageBox ("ParsePath failed", SEVERE);
    endif;
endfunction
```

```

else
    szMsg = "nOperation = FILENAME\n\nParsed Path: %s";
    sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svReturnString);
endif;

// Get file name without extension.
if (ParsePath (svReturnString, EXAMPLE_PATH, FILENAME_ONLY) < 0) then
    MessageBox ("ParsePath failed", SEVERE);
else
    szMsg = "nOperation = FILE_NAME_ONLY\n\nParsed Path: %s";
    sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svReturnString);
endif;

// Get the file extension.
if (ParsePath (svReturnString, EXAMPLE_PATH, EXTENSION_ONLY) < 0) then
    MessageBox ("ParsePath failed", SEVERE);
else
    szMsg = "nOperation = EXTENSION_ONLY\n\nParsed Path: %s";
    sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svReturnString);
endif;

end;

```

## ParseUrl

The **ParseUrl** function retrieves the parts of the specified URL. The function works with any valid URL.

### Syntax

```
ParseUrl ( szUrl, pISUrlComponents );
```

## Parameters

**Table 117** ▪ ParseUrl Parameters

| Parameter               | Description                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------|
| <b>szUrl</b>            | Specifies the URL to parse.                                                                           |
| <b>pISUrlComponents</b> | Returns a pointer to an ISURL_COMPONENTS data structure that contains the parts of the specified URL. |

## Return Values

**Table 118** ▪ ParseUrl Return Values

| Return Value  | Description                                                      |
|---------------|------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully parsed the path string. |
| <b>&lt; 0</b> | Indicates that the function was unable to parse the path string. |

## ParseUrl Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the ParseUrl function.
 *
 \*-----*/

function OnBegin()
    ISURL_COMPONENTS ISUrlComponents;
    STRING szUrl;
begin
    szUrl =
        "http://myusername:mypassword@www.mydomain.com:8080/" +
        "myfolder/mypage.asp?mykey=myvalue";
    ParseUrl ( szUrl, &ISUrlComponents );
    SprintfBox ( INFORMATION , "ParseUrl" ,
        "scheme = %s\nscheme number = %ld\nusername = %s\npassword = %s" +
        "\nhostname = %s\nport = %ld\nurlpath = %s\nextrainfo = %s",
        ISUrlComponents.szScheme, ISUrlComponents.nInternetScheme,
        /* nInternetScheme equals 3 for HTTP and 4 for HTTPS. */
        ISUrlComponents.szUserName, ISUrlComponents.szPassword,
        ISUrlComponents.szHostName, ISUrlComponents.nInternetPort,
        ISUrlComponents.szUrlPath, ISUrlComponents.szExtraInfo );
    abort;
end;

```

That script produces the following output:

**Figure 1:** ParseUrl Output

## PathAdd

The **PathAdd** function adds a path to the search path in the path buffer. With this function you can specify the position of the directory in relation to an existing directory in the path buffer. In addition, you can add the directory as the first or the last directory of the path buffer.

This function has no relationship to the path statement in the Autoexec.bat file or the path environment variable. It acts only on the path buffer, which helps you build, modify, and manipulate search paths. You can then add the modified path string to the Autoexec.bat file using the various batch file functions.

### Syntax

```
PathAdd ( szDir, szRefDir, bRefDir, bPosition );
```

## Parameters

**Table 119** ▪ PathAdd Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDir</b>     | <p>Specifies a path to add to the path buffer.</p>  <p><b>Note</b> ▪ If you specify a directory in szDir that currently exists in the path buffer, InstallShield does not duplicate it, and the position of the pre-existing directory is not modified. InstallShield ignores a backslash at the end of the directory name.</p>                                                                                                                                                                |
| <b>szRefDir</b>  | Specifies the path in the current path buffer relative to which the new path will be added.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>bRefDir</b>   | <p>Specifies whether or not szRefDir is a fully qualified path. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FULL</b>—szRefDir is a fully qualified path—it includes a drive designation and the complete path.</li> <li>● <b>PARTIAL</b>—szRefDir is the directory name only—without drive or path information.</li> </ul>                                                                                                                                                                                |
| <b>bPosition</b> | <p>Specifies the position relative to szRefDir at which szDir is to be inserted. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>AFTER</b>—Specifies that szDir is to be inserted after szRefDir. If szRefDir specifies a null string (""), szDir is inserted at the end of the path in the path buffer.</li> <li>● <b>BEFORE</b>—Specifies that szDir is to be inserted before szRefDir. If szRefDir specifies a null string (""), szDir is inserted at the front of the path in the path buffer.</li> </ul> |

## Return Values

**Table 120** ▪ PathAdd Return Values

| Return Value  | Description                                                                    |
|---------------|--------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully added a directory to the path buffer. |
| <b>&lt; 0</b> | Indicates that the function was unable to add a directory to the path buffer.  |

## PathAdd Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the PathAdd function.
```

```

*
* This example script shows how to add paths to a search path
* in the path buffer. It begins by initializing the path buffer
* with a search path. Then, it adds a new path to the front of
* the search path. Next, it gets the modified search path from
* the search buffer and displays it.
*
* It then initializes the path buffer with the modified search
* path and adds a new path before the last path in the path
* buffer. Finally, it gets the modified search path from the
* search buffer and displays it.
*
* Note: PathGet is called after the first PathAdd statement
*       only so the value of the path buffer can be displayed
*       for demonstration purposes. In a production script,
*       you would finish building the search path in the buffer
*       before calling PathGet.
*
\*-----*/

#define TITLE "Path buffer example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_PathAdd(HWND);

function ExFn_PathAdd(hMSI)
    STRING svSearchPath;
begin

    // Set up the search path to pass as a parameter to PathSet.
    svSearchPath = "C:\\DOS;C:\\Windows;C:\\Temp";

    // Initialize the path buffer.
    PathSet (svSearchPath);

    // Display the initial search path.
    sprintfBox (INFORMATION,TITLE,
        "The starting search path is %s.",svSearchPath);

    // Add C:\\MSOffice as the first path in the search path.
    if (PathAdd("C:\\MSOffice", "", FULL, BEFORE) < 0) then
        MessageBox ("Unable to add C:\\MsOffice to path buffer.", SEVERE);
        abort;
    endif;

    // Get the search path from the path buffer; this call also releases
    // the memory allocated for the path buffer.
    PathGet (svSearchPath);

    // Display the search path.
    // svSearchPath will contain C:\\MSOffice;C:\\DOS;C:\\Windows;C:\\Temp.
    sprintfBox (INFORMATION,TITLE,
        "C:\\MSOffice added before first path.\\n\\nThe search path is %s.",
        svSearchPath);

```

```

// Initialize path buffer to hold the search path.
PathSet (svSearchPath);

// Add C:\APP2 before C:\Temp in the path buffer.
if (PathAdd ("C:\\APP2", "Temp", PARTIAL, BEFORE) < 0) then
    MessageBox ("Unable to add C:\\APP2 to path buffer.", SEVERE);
    abort;
endif;

// Get the search path from the path buffer; this call also releases
// the memory allocated for the path buffer.
PathGet (svSearchPath);

// Display the modified search path.
// svSearchPath will contain C:\MSOffice;C:\DOS;C:\Windows;C:\App2;C:\Temp.
sprintfBox (INFORMATION,TITLE,
    "C:\\APP2 added before C:\\Temp.\n\nThe search path is %s.",
    svSearchPath);

end;

```

## PathDelete

The **PathDelete** function deletes a specific directory in the path buffer. You can specify the name of the directory or enter a fully qualified path.

This function has no relationship to the path statement in the Autoexec.bat file or the path environment variable. It acts only on the path buffer, which helps you build, modify, and manipulate search paths.

---

**Tip** ▪ Call **PathGet** to get the contents of the path buffer. Call **PathSet** to set contents of the path buffer.

### Syntax

```
PathDelete ( szDir, bDir );
```

## Parameters

**Table 121** ▪ PathDelete Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDir</b> | Specifies the path to remove from the path buffer.                                                                                                                                                                                                                                                                                                                                    |
| <b>bDir</b>  | Specifies whether or not szRefDir is a fully qualified path. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li><b>FULL</b>—szRefDir is a fully qualified path—it includes a drive designation and the complete path.</li> <li><b>PARTIAL</b>—szRefDir is the directory name only—without drive or path information.</li> </ul> |

## Return Values

**Table 122** ▪ PathDelete Return Values

| Return Value  | Description                                                                        |
|---------------|------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully deleted a directory from the path buffer. |
| <b>&lt; 0</b> | Indicates that the function was unable to delete a directory from the path buffer. |

## PathDelete Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the PathDelete function.
*
* This example script shows how to delete paths from the path
* buffer. It begins by initializing the path buffer with a
* search path. Then, it deletes any path that includes a
* reference to "Temp". Next, it gets the modified search path
* from the search buffer and displays it.
*
* It then initializes the path buffer with the modified search
* path and deletes a specific path. Finally, it gets the
* search path from the search buffer and displays it.
*
* Note: PathGet is called after the first PathDelete statement
* only so the value of the path buffer can be displayed
* for demonstration purposes. In a production script,
* you would finish building the search path in the buffer
```

```

*           before calling PathGet.
*
\*-----*/

#define TITLE "Path buffer example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_PathDelete(HWND);

function ExFn_PathDelete(hMSI)
    STRING svSearchPath;
begin

    // Set up the search path to pass as a parameter to PathSet.
    svSearchPath = "C:\\DOS;C:\\WINDOWS;C:\\TEMP;" +
        "C:\\EXAMPLE\\SOURCE;D:\\WORK\\TEMP";

    // Initialize the path buffer.
    PathSet (svSearchPath);

    // Display the initial search path.
    sprintfBox (INFORMATION,TITLE,
        "The starting search path is %s.",svSearchPath);

    // Delete C:\\Temp from the path buffer.
    if (PathDelete ("TEMP", PARTIAL) < 0) then
        MessageBox ("First call to PathDelete failed.", SEVERE);
    endif;

    // Get the search path from the path buffer; this call also releases
    // the memory allocated for the path buffer.
    PathGet (svSearchPath);

    // Display the search path.
    // svSearchPath will contain C:\\DOS;C:\\WINDOWS;C:\\EXAMPLE\\SOURCE.
    sprintfBox (INFORMATION, TITLE,
        "All paths referencing 'Temp' were deleted.\\n\\nThe search path is %s.",
        svSearchPath);

    // Set up the path buffer again.
    PathSet (svSearchPath);

    // Delete C:\\EXAMPLE\\SOURCE from the path buffer.
    if (PathDelete ("C:\\EXAMPLE\\SOURCE", FULL) < 0) then
        MessageBox ("Second call to PathDelete failed.",SEVERE);
    endif;

    // Get the search path from the path buffer; this call also releases
    // the memory allocated for the path buffer.
    PathGet (svSearchPath);

    // Display the search path.
    // svSearchPath will contain C:\\DOS;C:\\WINDOWS.
    sprintfBox (INFORMATION, TITLE,

```

```
        "C:\\EXAMPLE\\SOURCE was deleted.\\n\\nPath is %s.",  
        svSearchPath);  
  
    end;
```

## PathFind

The **PathFind** function searches the path buffer for a specific directory. You can specify the directory with either a fully qualified path or the directory name only.

This function has no relationship to the path statement in the Autoexec.bat file or the path environment variable. It acts only on the path buffer, which helps you build, modify, and manipulate search paths. You can then add this temporary path string to the Autoexec.bat file using the various batch file functions.

### Syntax

```
PathFind ( szDir, svResult, bDir, bSearch );
```

## Parameters

**Table 123** ▪ PathFind Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDir</b>    | Specifies the path to find in the path buffer.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>svResult</b> | Returns the full directory and path found in the path buffer returned by the function.                                                                                                                                                                                                                                                                                                                                                   |
| <b>bDir</b>     | Specifies whether or not szDir contains a fully qualified or an unqualified directory name. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>FULL</b>—szRefDir is a fully qualified path—it includes a drive designation and the complete path to a directory.</li> <li>● <b>PARTIAL</b>—szRefDir is the directory name only, without drive or path information.</li> </ul> |
| <b>bSearch</b>  | Specifies where to begin the search. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>CONTINUE</b>—Continues searching the path buffer at the location where the previous search was terminated.</li> <li>● <b>RESTART</b>—Starts the search from the beginning of the path buffer.</li> </ul>                                                                              |

## Return Values

**Table 124** ▪ PathFind Return Values

| Return Value  | Description                                                                                    |
|---------------|------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully searched the path buffer for a directory.             |
| <b>&lt; 0</b> | Indicates that the function was unable to successfully search the path buffer for a directory. |

## PathFind Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the PathSet, PathFind, and PathGet functions.
*
* First, PathSet is called to place a search path into the path
* buffer. Then PathFind is then called to search the path
* buffer for instances of a specific path. Finally, PathGet
```

```

    * is called to return the contents of the path buffer.
    *
    \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_PathFind(HWND);

function ExFn_PathFind(hMSI)
    STRING szString, szMsg, svResult, svString, szDir;
    NUMBER nResult;
    BOOL    bDir, bSearch;
begin

    // Set up the search path to pass as a parameter to PathSet.
    szString = "C:\\DOS;C:\\USERS\\BIN;C:\\MSC\\BIN;";

    // Place the search path into the path buffer
    if (PathSet (szString) < 0) then
        // Report an error; then terminate.
        MessageBox ("PathSet failed.", SEVERE);
        abort;
    else
        szMsg = "PathSet set the path buffer to: %s";
        sprintfBox (INFORMATION, "PathSet Example", szMsg, szString);
    endif;

    // Set PathFind variables.
    szDir = "BIN";

    // Search the path buffer for paths that include a folder named "BIN".
    nResult = PathFind(szDir, svResult, PARTIAL, RESTART);

    // Error check PathFind.
    if (nResult < 0) then
        MessageBox("PathFind failed.", SEVERE);
        abort;
    endif;

    // Loop through the string to find all occurrences of the szDir string.

    while (nResult = 0)
        sprintfBox(INFORMATION, "PathFind example",
            "Search for %s.\n\nFound: %s", szDir, svResult);
        nResult = PathFind(szDir, svResult, PARTIAL, CONTINUE);
    endwhile;

    // Get the contents of the path buffer.
    if (PathGet (svString) < 0) then
        MessageBox ("PathGet failed.", SEVERE);
    else
        // Display the path string.
        sprintfBox (INFORMATION, "Path Get Example", "Path is: %s", svString);
    endif;
end;

```

end;

# PathGet

The **PathGet** function retrieves the search path currently stored in the path buffer, which is a temporary storage area created by a call to PathSet. The path buffer enables you to build and edit a search path. When the path you are editing is complete, call PathGet to place the search path into a string variable so that you can pass it to other functions in your setup.

This function has no relationship to the path statement in the Autoexec.bat file or the path environment variable. It acts on the path buffer only, which helps you build, modify, and manipulate search paths. You can then add this temporary path string to the Autoexec.bat file using the appropriate batch file functions.

**Tip** ▪ PathGet retrieves the search path from the path buffer and releases the memory allocated to the path buffer. A subsequent call to PathGet will fail unless the path buffer is reinitialized by a call to **PathSet**.

## Syntax

PathGet ( svString );

## Parameters

Table 125 ▪ PathGet Parameters

| Parameter | Description                              |
|-----------|------------------------------------------|
| svString  | Returns the contents of the path buffer. |

## Return Values

Table 126 ▪ PathGet Return Values

| Return Value | Description                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully retrieved the path currently stored in the path buffer.                         |
| < 0          | Indicates that the function was unable to retrieve the path string currently stored in the temporary path string buffer. |

## PathGet Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* Demonstrates the PathSet, PathFind, and PathGet functions.
*
* First, PathSet is called to place a search path into the path
* buffer. Then PathFind is then called to search the path
* buffer for instances of a specific path. Finally, PathGet
* is called to return the contents of the path buffer.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_PathGet(HWND);

function ExFn_PathGet(hMSI)
    STRING szString, szMsg, svResult, svString, szDir;
    NUMBER nResult;
    BOOL    bDir, bSearch;
begin

    // Set up the search path to pass as a parameter to PathSet.
    szString = "C:\\DOS;C:\\USERS\\BIN;C:\\MSC\\BIN;";

    // Place the search path into the path buffer
    if (PathSet (szString) < 0) then
        // Report an error; then terminate.
        MessageBox ("PathSet failed.", SEVERE);
        abort;
    else
        szMsg = "PathSet set the path buffer to: %s";
        sprintfBox (INFORMATION, "PathSet Example", szMsg, szString);
    endif;

    // Set PathFind variables.
    szDir = "BIN";

    // Search the path buffer for paths that include a folder named "BIN".
    nResult = PathFind(szDir, svResult, PARTIAL, RESTART);

    // Error check PathFind.
    if (nResult < 0) then
        MessageBox("PathFind failed.", SEVERE);
        abort;
    endif;

    // Loop through the string to find all occurrences of the szDir string.
    while (nResult = 0)
        sprintfBox(INFORMATION, "PathFind example",
            "Search for %s.\n\nFound: %s", szDir, svResult);
        nResult = PathFind(szDir, svResult, PARTIAL, CONTINUE);
    endwhile;

    // Get the contents of the path buffer.
    if (PathGet (svString) < 0) then
        MessageBox ("PathGet failed.", SEVERE);
    endif;
endfunction

```

```

else
    // Display the path string.
    sprintfBox (INFORMATION, "Path Get Example" ,"Path is: %s", svString);
endif;

end;

```

## PathMove

The **PathMove** function repositions a directory in the path buffer to another location. You can also use this function to position the directory relative to another directory or as the first or the last item in the path string.

This function has no relation to the PATH statement in the Autoexec.bat file or the PATH environment variable. It acts only on the path buffer, which helps you build, modify, and manipulate search paths. You can then add this temporary path string to Autoexec.bat using the various batch file functions.

---

**Tip** ▪ Call **PathGet** to get the contents of the path buffer. Call **PathSet** to set contents of the path buffer.

### Syntax

```
PathMove ( szDir, szRefDir, bDir, bRefDir, bPosition );
```

## Parameters

**Table 127** ▪ PathMove Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDir</b>     | Specifies a full or partial path to reposition in the path buffer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>szRefDir</b>  | Specifies the path in the path buffer relative to which the path in szDir will be moved. To move the path in szDir to the beginning or end of the path in the path buffer, pass a null string ("" ) in this parameter.                                                                                                                                                                                                                                                                                                                                                          |
| <b>bDir</b>      | Specifies whether szDir contains a fully qualified or an unqualified directory name. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>FULL</b>—Specifies that szDir contains a fully qualified directory name.</li> <li>● <b>PARTIAL</b>—Specifies that szDir contains the directory name only.</li> </ul>                                                                                                                                                                                                         |
| <b>bRefDir</b>   | Specifies whether szRefDir contains a fully qualified or an unqualified directory name. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>FULL</b>—Specifies that szRefDir contains a fully qualified directory name.</li> <li>● <b>PARTIAL</b>—Specifies that szRefDir contains the directory name only.</li> </ul>                                                                                                                                                                                                |
| <b>bPosition</b> | Specifies the position relative to szRefDir to which szDir is to be moved. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>AFTER</b>—Specifies that szDir is to be positioned after szRefDir. If szRefDir specifies a null string ("" ), szDir is positioned at the end of the path in the path buffer.</li> <li>● <b>BEFORE</b>—Specifies that szDir is to be positioned before szRefDir. If szRefDir specifies a null string ("" ), szDir is positioned at the front of the path in the path buffer.</li> </ul> |

## Return Values

**Table 128** ▪ PathMove Return Values

| Return Value  | Description                                                                           |
|---------------|---------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully repositioned a directory in the path buffer. |
| <b>&lt; 0</b> | Indicates that the function was unable to reposition a directory in the path buffer.  |

## PathMove Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function,

execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the PathMove functions.
*
* This example script shows how to reposition paths in the path
* buffer. It begins by initializing the path buffer with a
* search path. Then, it moves one path ahead of another.
* Next, it gets the modified search path from the search buffer
* and displays it.
*
* It then initializes the path buffer with the modified search
* path and moves one path after another path. Finally, it gets
* the modified search path from the search buffer and displays
* it.
*
* Note: PathGet is called after the first PathMove statement
*       only so the value of the path buffer can be displayed
*       for demonstration purposes. In a production script,
*       you would finish building the search path in the buffer
*       before calling PathGet.
*
\*-----*/

#define TITLE "Path buffer example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_PathMove(HWND);

function ExFn_PathMove(hMSI)
    STRING svSearchPath;
begin

    // Set up the search path to pass as a parameter to PathSet.
    svSearchPath = "C:\\MsOffice;C:\\DOS;C:\\Windows;C:\\App2;C:\\Temp";

    // Initialize the path buffer.
    PathSet (svSearchPath);

    // Display the initial search path.
    sprintfBox (INFORMATION, TITLE,
        "The starting search path is %s.",svSearchPath);

    // Move C:\\App2 before C:\\DOS.
    if (PathMove("C:\\App2", "C:\\DOS", FULL, FULL, BEFORE) < 0) then
        MessageBox ("Unable to move C:\\App2.", SEVERE);
        abort;
    endif;

    // Get the search path from the path buffer and release
    // the memory allocated for the path buffer.

```

```

PathGet (svSearchPath);

// Display the search path.
// svSearchPath will contain C:\MSOFFICE;C:\APP2;C:\DOS;C:\WINDOWS;C:\TEMP
sprintfBox (INFORMATION, TITLE,
            "C:\\App2 moved before C:\\DOS.\n\nThe search path is %s.",
            svSearchPath);

// Initialize the path buffer with the search path.
PathSet (svSearchPath);

// Move C:\DOS after C:\Temp.
if (PathMove ("C:\\DOS", "TEMP", FULL, PARTIAL, AFTER) < 0) then
    MessageBox ("Unable to move C:\\DOS.", SEVERE);
endif;

// Get the search path from the path buffer and release
// the memory allocated for the path buffer.
PathGet (svSearchPath);

// Display the search path.
// svSearchPath will contain C:\MSOFFICE;C:\APP2;C:\WINDOWS;C:\TEMP;C:\DOS
sprintfBox (INFORMATION, TITLE,
            "C:\\DOS moved after C:\\Temp.\n\nThe search path is %s.",
            svSearchPath);

end;

```

## PathSet

The **PathSet** function stores a search path string in the path buffer. You can then manipulate this buffer using the other path functions. The value of szString should be an absolute path (a path that includes a drive specification, for example, "C:\\Program Files\\AppName").

This function has no relation to the PATH statement in the Autoexec.bat file or the PATH environment variable. It acts only on the path buffer, which helps you build, modify, and manipulate search paths. You can then add this temporary path string to the Autoexec.bat file or PATH environment variable.

### Syntax

```
PathSet ( szString );
```

## Parameters

**Table 129** ▪ PathSet Parameters

| Parameter       | Description                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szString</b> | Specifies a search path to store in the path buffer. The search path should be fully qualified; that is it should include a drive designation and the complete path to a directory. |

## Return Values

**Table 130** ▪ PathSet Return Values

| Return Value  | Description                                                                              |
|---------------|------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully stored a search path string in the path buffer. |
| <b>&lt; 0</b> | Indicates that the function was unable to store a search path string in the path buffer. |

## PathSet Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the PathSet, PathFind, and PathGet functions.
 *
 * First, PathSet is called to place a search path into the path
 * buffer. Then PathFind is then called to search the path
 * buffer for instances of a specific path. Finally, PathGet
 * is called to return the contents of the path buffer.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_PathSet(HWND);

function ExFn_PathSet(hMSI)
    STRING szString, szMsg, svResult, svString, szDir;
    NUMBER nResult;
    BOOL bDir, bSearch;
begin

    // Set up the search path to pass as a parameter to PathSet.
```

```

szString = "C:\\DOS;C:\\USERS\\BIN;C:\\MSC\\BIN;";

// Place the search path into the path buffer
if (PathSet (szString) < 0) then
    // Report an error; then terminate.
    MessageBox ("PathSet failed.", SEVERE);
    abort;
else
    szMsg = "PathSet set the path buffer to: %s";
    sprintfBox (INFORMATION, "PathSet Example", szMsg, szString);
endif;

// Set PathFind variables.
szDir = "BIN";

// Search the path buffer for paths that include a folder named "BIN".
nResult = PathFind(szDir, svResult, PARTIAL, RESTART);

// Error check PathFind.
if (nResult < 0) then
    MessageBox("PathFind failed.", SEVERE);
    abort;
endif;

// Loop through the string to find all occurrences of the szDir string.
while (nResult = 0)
    sprintfBox(INFORMATION, "PathFind example",
        "Search for %s.\n\nFound: %s", szDir, svResult);
    nResult = PathFind(szDir, svResult, PARTIAL, CONTINUE);
endwhile;

// Get the contents of the path buffer.
if (PathGet (svString) < 0) then
    MessageBox ("PathGet failed.", SEVERE);
else
    // Display the path string.
    sprintfBox (INFORMATION, "Path Get Example" ,"Path is: %s", svString);
endif;

end;

```

## PlaceBitmap

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **PlaceBitmap** function inserts an image into the installation window. The image source is specified by szName; it can be a bitmap file (.bmp), metafile (.wmf file), or dynamic link library (.dll).

## Syntax

```
PlaceBitmap ( szName, nID_BITMAP, nDx, nDy, nDrawOp );
```

## Parameters

**Table 131** • PlaceBitmap Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szName</b>     | <p>Specifies the fully qualified name of the bitmap file (.bmp), metafile (.wmf file), or dynamic link library (.dll) of the image to be displayed. InstallShield recognizes bitmap files and metafiles by their file extension. Bitmap files must have the extension .bmp. Metafiles must have the extension .wmf. Dynamic link libraries must have the extension .dll. If a file name is specified with no extension, InstallShield assumes the extension .dll.</p> <p>To specify an alternate transparent color, place a semicolon after the file name and follow it with a set of RGB color values. (RGB color is specified with three numeric values, separated by commas.) That color is then used as the transparent color for the bitmap specified by szName. Note that it does <i>not</i> affect bitmaps that are already displayed; nor does it become the default transparent color for bitmaps displayed by subsequent calls to PlaceBitmap.</p> <p>The parameter below specifies white as the transparent color:</p> <p>SUPPORTDIR ^ "Bitmap.bmp;255,255,255" When nDrawOptions is set to REMOVE, this parameter is ignored.</p> |
| <b>nID_BITMAP</b> | <p>Specifies the bitmap's resource ID if the bitmap resides in a .dll. If the bitmap source is a metafile or bitmap file, specifies a value that is not in use for an image currently on display; images that are displayed simultaneously must have unique ID numbers. When nDrawOptions is set to REMOVE, this parameter must contain the ID of a displayed image.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>nDx</b>        | <p>Pass either a number or the CENTERED constant in this parameter:</p> <ul style="list-style-type: none"> <li>● Pass a number to specify the horizontal distance in pixels between the edge of installation window and the edge of the image when nDrawOp is set to LOWER_LEFT, LOWER_RIGHT, UPPER_LEFT, or UPPER_RIGHT.</li> <li>● Pass the CENTERED constant to center the image on the horizontal axis when nDrawOp is set to LOWER_LEFT, LOWER_RIGHT, UPPER_LEFT, or UPPER_RIGHT. The image will be offset from the upper or lower edge of the installation window by the number of pixels specified in nDy. Since the CENTERED constant — when passed in nDx — centers the image horizontally, the argument in nDrawOp will affect only the vertical placement of the image.</li> </ul>                                                                                                                                                                                                                                                                                                                                                 |

**Table 131** ▪ PlaceBitmap Parameters (cont.)

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nDy</b> | <p>Pass either a number or the <code>CENTERED</code> constant in this parameter:</p> <ul style="list-style-type: none"> <li>• Pass a number to specify the vertical distance in pixels between the edge of installation window and the edge of the image when <code>nDrawOp</code> is set to <code>LOWER_LEFT</code>, <code>LOWER_RIGHT</code>, <code>UPPER_LEFT</code>, or <code>UPPER_RIGHT</code>.</li> <li>• Pass the <code>CENTERED</code> constant to center the image on the vertical axis when <code>nDrawOp</code> is set to <code>LOWER_LEFT</code>, <code>LOWER_RIGHT</code>, <code>UPPER_LEFT</code>, or <code>UPPER_RIGHT</code>. The image will be offset from the right or left edge of the installation window by the number of pixels specified in <code>nDx</code>. Since the <code>CENTERED</code> constant — when passed in <code>nDy</code> — centers the image vertically, the argument in <code>nDrawOp</code> will affect only the horizontal placement of the image.</li> </ul> |
|            |  <p><b>Note</b> ▪ You can pass the <code>CENTERED</code> constant in both the <code>nDx</code> and <code>nDy</code> parameters to center the image in the installation window. This is equivalent to passing the <code>CENTERED</code> constant in the <code>nDrawOp</code> parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 131** ▪ PlaceBitmap Parameters (cont.)

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nDrawOp</b>             | <p>Specifies the bitmap's placement location, sets placement options, or removes a previously placed bitmap. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>BITMAPICON</b>—Indicates that the bitmap has transparent parts. You can use the bitwise OR operator (   ) to combine this constant with any of the other constants except <b>TILED</b>, <b>FULLSCREEN</b> or <b>FULLSCREENSIZE</b>. When <b>BITMAPICON</b> is ORed with one of those constants, the bitwise operation is ignored and <b>BITMAPICON</b> is used.</li> </ul> <p><b>BITMAPICON</b> has no effect when <b>szName</b> specifies a metafile or a 24-bit bitmap. Note that when you specify <b>BITMAPICON</b>, the bitmap is displayed normally, even if a special effect has been enabled with <b>SetDisplayEffect</b>.</p> <ul style="list-style-type: none"> <li>● <b>TILED</b>—The bitmap is tiled across the main installation window. This constant is normally used to create an installation background. When this constant is specified, location options are ignored and the bitmap is displayed normally, even if a special effect has been enabled with <b>SetDisplayEffect</b>.</li> <li>● <b>FULLSCREEN</b>—Draw the image to fill the entire installation window. The image is not resized when its drawn. If a bitmap image is smaller than the InstallShield main window, it is centered in the window and the background is filled with the current background color. The default value is teal; it can be changed using the <b>SetColor</b> function. When this constant is specified, location options are ignored and the bitmap is displayed normally, even if a special effect has been enabled with <b>SetDisplayEffect</b>.</li> <li>● <b>FULLSCREENSIZE</b>—Draw and stretch the image to fill the entire installation window. When this constant is specified, location options are ignored and the bitmap is displayed normally, even if a special effect has been enabled with <b>SetDisplayEffect</b>.</li> </ul> |
| <b>nDrawOp (continued)</b> | <ul style="list-style-type: none"> <li>● <b>CENTERED</b>—Places the bitmap in the center of the installation window.</li> <li>● <b>LOWER_LEFT</b>—Places the bitmap in the lower left corner of the InstallShield installation window.</li> <li>● <b>LOWER_RIGHT</b>—Places the bitmap in the lower right corner of the InstallShield installation window.</li> <li>● <b>UPPER_LEFT</b>—Places the bitmap in the upper left corner of the InstallShield installation window.</li> <li>● <b>UPPER_RIGHT</b>—Places the bitmap in the upper right corner of the InstallShield installation window.</li> <li>● <b>REMOVE</b>—Removes a previously placed bitmap or metafile. Any special display effects that have been enabled with <b>SetDisplayEffect</b> are ignored.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Return Values

**Table 132** ▪ PlaceBitmap Return Values

| Return Value | Description                                                          |
|--------------|----------------------------------------------------------------------|
| 0            | Indicates that the function successfully found and placed the image. |
| < 0          | Indicates that the function was unable to find or place the image.   |

## Comments

InstallShield supports 2-color, 16-color, 256-color and true color (24-bit) bitmaps. Two-color, 16-color and 256-color bitmaps can have transparent portions.

Transparent bitmaps are useful for displaying images that appear to be integrated with the background window. Pixels in the bitmap that match a specified transparent color are not displayed; the background pixel at that location remains visible. In setups, transparent bitmaps that incorporate the company name and its logo in an artful design are often used as titles in the installation window.

To specify a transparent bitmap, you must pass the constant `BITMAPICON` in the parameter `nDrawOp`. You must also consider which color in the bitmap is to be transparent. The default transparent color is purple (`RGB(255,0,255)`). To specify a different transparent color, use the parameter `szName` as described below.

Because metafiles are drawn rather than placed, they are intrinsically transparent. If `BITMAPICON` is specified for a metafile, that parameter is ignored.

**Note** ▪ Many special display effects are available for non-transparent bitmaps by using the [SetDisplayEffect](#) function. That function also provides limited display effects for metafiles.

The location of the bitmap within the window can be specified in one of two ways:

- By passing one of the location constants in the parameter `nDrawOp`.
- By passing a vertical and horizontal offset from the edge of the installation window in `nDx` and `nDy`.
- By passing the `CENTERED` constant in either `nDx` or `nDy` in combination with a horizontal or vertical offset.

Always remove any bitmaps or metafiles that are no longer needed by calling `PlaceBitmap` with the constant `REMOVE` as the parameter `nDrawOp`. Removing an unneeded bitmap is recommended even if another bitmap covers that bitmap completely because the palette entries for the first bitmap will not be released until the bitmap is removed.

**Tip** ▪ A true color bitmap that is displayed on a system running in 16-color or 256-color mode will use only those colors available in the color palette; no additional colors will be allocated for the bitmap, even when additional color palette entries are available. If you anticipate that a setup with 24-bit bitmaps will be run on 16- or 256-color systems, include 16- or 256-color versions of the bitmaps. Then call [GetSystemInfo](#) with the `COLORS` parameter to determine the current color mode before selecting the bitmap to display.

Call `SetDisplayEffect` to set special effects for non-tiled, full-screen, transparent bitmaps; you can also set limited special effects for metafiles.

InstallShield does not support 24-bit transparent bitmaps. If you include a transparent color in a 24-bit bitmap and specify the `BITMAPICON` constant, the color will be displayed normally.

When you place a 256-color bitmap on a system running in 256-color mode, InstallShield attempts to allocate the bitmap's color palette into the system color palette. If multiple 256-color bitmaps are placed, InstallShield attempts to merge the color palettes of all visible bitmaps into the system color palette, giving precedence to the most recently placed bitmap. This behavior may cause previously placed bitmaps to change colors when additional bitmaps are displayed.

On a system running in 256-color mode with a 256-color dithered background, bitmaps that include many colors may cause some of the color palette entries used for the background to be reallocated; this can cause a gradient effect to appear in the background. Setups with bitmaps that use many colors should not use a 256-color gradient background if they will run on 256-color systems.

System color palettes exist only on systems that are running in 256-color mode. Systems running in high color (16-bit) or true color (24-bit) modes and systems running under in 65535 (16-bit) color mode do not have a system color palette. On these systems there are no color palette handling issues to consider; colors are displayed directly using the RGB color value. See [Preventing Color Distortion](#) for more information.

Because metafiles are rendered, they do not include a custom color palette. When a metafile is displayed on a 256-color system, no color palette handling takes place; the metafile is drawn with the colors currently available in the color palette. For that reason, you should not use metafiles that display colors other than the standard 16 colors in setups that will run on 256-color systems.

## PlaceBitmap Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the PlaceBitmap function.
 *
 * PlaceBitmap is called to display and remove bitmaps on the
 * screen. The SetDisplayEffect function sets the display
 * effect for the bitmap.
 *
 * Note: Before running this script, set the constant BMP_PATH
 *       so that it references an existing bitmap file on the
 *       target system.
 *
 \*-----*/

#define BMP_PATH  "C:\\Windows\\Bubbles.bmp"
#define BITMAP_ID_1 12
#define BITMAP_ID_2 13
#define BITMAP_ID_3 14

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_Placebitmap(HWND);

function ExFn_Placebitmap(hMSI)
begin
```

```

Enable ( BACKGROUND );

// Display the bitmap in the upper left corner.
PlaceBitmap (BMP_PATH, BITMAP_ID_1, 10, 12, UPPER_LEFT);

// Set bitmap reveal effect.
SetDisplayEffect (EFF_REVEAL);

// Display the bitmap in the lower right corner.
PlaceBitmap (BMP_PATH, BITMAP_ID_2, 10, 10, LOWER_RIGHT);

Delay(3);

// Remove the bitmap in the upper left corner.
PlaceBitmap ("", BITMAP_ID_2, 0, 0, REMOVE);

// Remove the bitmap in the lower right corner.
PlaceBitmap ("", BITMAP_ID_1, 0, 0, REMOVE);

// Set bitmap fade in effect.
SetDisplayEffect (EFF_FADE);

// Display the bitmap at the center of screen.
PlaceBitmap (BMP_PATH, BITMAP_ID_3, CENTERED, CENTERED, 0);
Delay (3);

// Remove the bitmap at the center of the screen.
PlaceBitmap ("", BITMAP_ID_3, 0, 0, REMOVE);
Delay (1);

end;

```

## PlaceWindow

The **PlaceWindow** function changes the position of user interface objects. This includes billboards, Adobe Flash application files, and AVI files that are displayed at run time through **PlayMMedia**. Specify the distance between the sides of the object and the edges of the screen in nDx and nDy.

When using this function, be aware that an installation runs on a variety of screen resolutions. You may want to determine the extents of the screen before you position the objects. The distance is measured in pixels and is between the edge of the object and the edge of the corner of the specified screen.

---

**Note** - The **PlaceWindow** function does not have any effect on the type of billboard that is displayed on a progress dialog. To learn more about the different types of billboards, see *Billboard Styles and File Types for InstallScript and InstallScript MSI Projects*.

### Restrictions

This function cannot be used to position message boxes or custom dialogs.

- Message boxes cannot be positioned with this function because they are created using the Windows API. A message box's position is determined by the Windows API and is not under the control of an installation.
- Custom dialogs cannot be positioned with this function. **PlaceWindow** does not work in conjunction with the **AskOptions**, **AskPath**, **AskText**, or **EnterDisk** functions. By default, a dialog appears in the center of the desktop, unless the background window mode is enabled. If the installation is in window mode, the dialog appears in the center of the background window.

## Syntax

```
PlaceWindow ( nObject, nDx, nDy, nCorner );
```

## Parameters

**Table 133** ▪ PlaceWindow Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nObject</b> | <p>Specifies the object whose position is to be changed. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>ASKOPTIONS</b>—Moves the <a href="#">AskOptions</a> dialog.</li> <li>● <b>ASKPATH</b>—Moves the <a href="#">AskPath</a> dialog.</li> <li>● <b>ASKTEXT</b>—Moves the <a href="#">AskText</a> dialog.</li> <li>● <b>BACKGROUND</b>—Moves the background window.</li> <li>● <b>BILLBOARD</b>—Sets the location of billboards used during the file transfer process.</li> <li>● <b>ENTERDISK</b>—Moves the <a href="#">EnterDisk</a> dialog.</li> <li>● <b>MMEDIA_AVI</b>—Sets the window position for the next .avi file to be played. By default, the .avi file is played at run time in a window in the left corner of the screen, 10 pixels from the left and 10 pixels from the top.</li> <li>● <b>MMEDIA_SWF</b>—Sets the window position for the Adobe Flash application file (.swf) to be played.</li> <li>● <b>STATUS</b>—Moves the progress indicator.</li> <li>● <b>STATUSDLG</b>—Moves the dialog style progress indicator.</li> <li>● <b>STATUSEX</b>—Moves the Setup Status dialog.</li> <li>● <b>STATUSOLD</b>—Moves the old style progress indicator.</li> </ul> <p></p> <p><b>Tip</b> ▪ When you call <i>PlaceWindow</i> to move the progress indicator or status dialog, be sure to pass the correct constant for the feedback object you have enabled in your setup. For example, if you called <a href="#">Enable</a> (<b>STATUSOLD</b>), you must pass <b>STATUSOLD</b> to <i>PlaceWindow</i>.</p> |
| <b>nDx</b>     | Specifies the distance in pixels between the appropriate edge of the object and the edge of the screen on the horizontal axis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>nDy</b>     | Specifies the distance in pixels between the appropriate edge of the object and the edge of the screen on the vertical axis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 133** ▪ PlaceWindow Parameters (cont.)

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nCorner</b> | <p>Specifies from which corner to measure the distances expressed in nDx and nDy. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>LOWER_LEFT</b>—Measures nDx from the left and nDy from the bottom of the main InstallShield window.</li> <li>• <b>LOWER_RIGHT</b>—Measures the nDx from the right and nDy from the bottom of the main InstallShield window.</li> <li>• <b>UPPER_LEFT</b>—Measures the nDx from the left and nDy from the top of the main InstallShield window.</li> <li>• <b>UPPER_RIGHT</b>—Measures the nDx from the right and nDy from the top of the main InstallShield window.</li> <li>• <b>CENTERED</b>—Centers the user interface object within the window.</li> </ul> <p></p> <p><b>Note</b> ▪ <i>CENTERED can also be placed in nDx or nDy to center an object only horizontally or only vertically.</i></p> |

## Return Values

**Table 134** ▪ PlaceWindow Return Values

| Return Value  | Description                                                                  |
|---------------|------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully changed the position of the object. |
| <b>&lt; 0</b> | Indicates that the function was unable to change the position of the object. |

## Additional Information

Use the [PlayMMedia](#) function if you want your installation to play an Adobe Flash application file (.swf) or an AVI file.

## PlaceWindow Example

**Note** ▪ *To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.*

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the PlaceWindow function.
*

```

```

* PlaceWindow is called to place the background window 50
* pixels to the right and below the upper left-hand corner
* of the display.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_PlaceWindow(HWND);

function ExFn_PlaceWindow(hMSI)
begin

    Enable ( BACKGROUND );

    Enable ( DEFWINDOWMODE );

    MessageBox ("This is the default position of the background window.",
                INFORMATION);

    // Delay calling PlaceWindow for three seconds.
    Delay(3);

    // Change the position of the background window.
    if (PlaceWindow (BACKGROUND, 50, 50, UPPER_LEFT) < 0) then
        MessageBox ("PlaceWindow failed.", SEVERE);
    else
        MessageBox ("This is the new position of the background window.",
                    INFORMATION);
        // Delay exiting script for three seconds.
        Delay(3);
    endif;

end;

```

## PlayMMedia

The **PlayMMedia** function plays an Adobe Flash application file (.swf), an AVI file, or a sound file (MIDI or WAVE).

**Tip** ▪ If you are using **PlayMMedia** to display an Flash file or an AVI file, the installation must display a background window. For more information, see *Displaying a Background Window in InstallScript and InstallScript MSI Installations*.

*InstallShield has support for displaying a Flash file as a billboard for your installation without displaying a background window. To learn more, see *Billboard Styles and File Types for InstallScript and InstallScript MSI Projects*.*

### Syntax

```
PlayMMedia (nType, szFileName, nOperation, nReserved);
```

## Parameters

**Table 135** ▪ PlayMMedia Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nType</b>      | <p>Specify the type of file that you want your installation to play. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>MMEDIA_AVI</b>—The file is an AVI file.</li> <li>• <b>MMEDIA_MIDI</b>—The file is of MIDI sound format.</li> <li>• <b>MMEDIA_SWF</b>—The file is an Adobe Flash application file (.swf).</li> <li>• <b>MMEDIA_WAVE</b>—The file is of WAVE sound format.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szFileName</b> | Specify the fully qualified name of the file to be played.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>nOperation</b> | <p>Specify the play mode. Pass any of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>MMEDIA_PLAYSYNCH</b>—Play synchronously.</li> <li>• <b>MMEDIA_PLAYASYNCH</b>—Play asynchronously. This constant can be combined with <b>MMEDIA_PLAYCONTINUOUS</b> by using the OR operator ( ).</li> <li>• <b>MMEDIA_PLAYCONTINUOUS</b>—Play in a continuous loop. This value cannot be used when playing a sound/AVI file in synchronous mode. It can be used only with files being played in asynchronous mode. Combine it with <b>MMEDIA_PLAYASYNCH</b> by using the OR operator ( ).</li> <li>• <b>MMEDIA_STOP</b>—Stop playing.</li> </ul> <p></p> <p><b>Note</b> ▪ A Flash file plays only once asynchronously, regardless of whether any <b>MMEDIA_PLAY*</b> constants are passed in <b>nOperation</b>.</p> |
| <b>nReserved</b>  | Pass the number zero in this parameter. No other value is allowed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Return Values

**Table 136** ▪ PlayMMedia Return Values

| Return Value  | Description                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | The function successfully played the file.                                                                                                                                                               |
| <b>&lt; 0</b> | <p>The function was unable to play the file.</p> <p>One example of when this occurs is if you specified a Flash file for <b>PlayMMedia</b> but the Flash Player is not present on the target system.</p> |

## Additional Information

If you are using a Flash file or an AVI file, you can use **SizeWindow** and **PlaceWindow** to control the size and placement of the background window that displays the Flash or AVI file.

## PlayMMedia Example

To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the PlayMMedia function.
*
* This script plays an AVI file during the setup.
*
* Note: To run this example script, create a project (or
*       insert into project) with several features and/or
*       subfeatures with components containing files. Then
*       add an AVI file to Disk 1 in the Support Files view in
*       the IDE. Change the file name in #define SOURCE line
*       below to specify your AVI file.
*
* Warning: Since this example does not include uninstallation
*          functionality, use this example only with projects
*          that do not overwrite important files, install
*          shared files, or update the registry.
*
\*-----*/

#define SOURCE  SRCDIR + "windy7(1).avi"
#define TITLE1  "Playing AVI synchronously..."
#define TITLE2  "Playing AVI asynchronously and continuously..."

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_PlayMMedia(HWND);

function ExFn_PlayMMedia(hMSI)
    NUMBER nvDisk;
begin

    Enable ( BACKGROUND );

    // First, play the AVI synchronously to demonstrate how this causes
    // it to play by itself, with no other events taking place.
    SetTitle (TITLE1, 16, YELLOW);
    PlaceWindow (MMEDIA_AVI, 10, 10, UPPER_RIGHT);

    if (PlayMMedia (MMEDIA_AVI, SOURCE, MMEDIA_PLAYSYNCH, 0) < 0) then
        MessageBox ("Unable to play AVI file.", WARNING);
    endif;

    // Now play the AVI asynchronously. The AVI continues executing
```

```

    // as the file transfer occurs.
    SetTitle (TITLE2, 16, YELLOW);

    PlaceWindow (MMEDIA_AVI, 10, 10, LOWER_RIGHT);

    if (PlayMMedia (MMEDIA_AVI, SOURCE,
                    MMEDIA_PLAYASYNCH | MMEDIA_PLAYCONTINUOUS, 0) < 0) then
        MessageBox ("Unable to play AVI file.", WARNING);
    endif;

    Enable (STATUSDLG);
    Enable (INDVFILESTATUS);

    StatusUpdate (ON, 99);

    // Transfer the files.
    ComponentMoveData (MEDIA, nvDisk, 0);

    Disable (INDVFILESTATUS);
    Disable (STATUSDLG);

    // The AVI will stop playing when the setup exits. But you can
    // stop it explicitly like this:
    PlayMMedia (MMEDIA_AVI, SOURCE, MMEDIA_STOP, 0);

end;

```

## PostShowComponentDlg

**Caution** ▪ This function is not supported in InstallShield because it is no longer required. The functions that required `PreShowComponentDlg` in InstallShield Professional 2.03 are not supported for use in Basic MSI projects. If you want to use one of these functions in your setup project, you must convert your Basic MSI project to the InstallScript MSI project type and add the function to the script.

The **PostShowComponentDlg** function converts InstallShield Professional components back to InstallShield–Windows Installer Edition features. You must call `PostShowComponentDlg` after calling a component dialog or function in your script. This function selects Windows Installer features based upon component selection.

### Syntax

```
PostShowComponentDlg (hMSI);
```

## Parameters

**Table 137** ▪ PostShowComponentDlg Parameters

| Parameter | Description                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------|
| hMSI      | The handle to the Windows Installer (MSI) database that is passed to your entry-point function. |

## Return Values

**Table 138** ▪ PostShowComponentDlg Return Values

| Return Value | Description                                                                                                                  |
|--------------|------------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully converted InstallShield Professional components back to Windows Installer features. |
| < 0          | Indicates that the function was unable to convert InstallShield Professional components back to Windows Installer features.  |

# PreShowComponentDlg

**Caution** ▪ This function is not supported in InstallShield because it is no longer required. The functions that required PreShowComponentDlg in InstallShield Professional 2.03 are not supported for use in Basic MSI projects. If you want to use one of these functions in your setup project, you must convert your Basic MSI project to the InstallScript MSI project type and add the function to the script.

The **PreShowComponentDlg** function converts InstallShield–Windows Installer Edition features to InstallShield Professional components. It also initializes feature costing functionality.

## Syntax

```
PreShowComponentDlg (hMSI);
```

## Parameters

**Table 139** ▪ PreShowComponentDlg Parameters

| Parameter | Description                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------|
| hMSI      | The handle to the Windows Installer (MSI) database that is passed to your entry-point function. |

## Return Values

**Table 140** ▪ PreShowComponentDlg Parameters

| Return Value | Description                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully converted Windows Installer features to InstallShield Professional components. |
| < 0          | Indicates that the function was unable to convert Windows Installer features to InstallShield Professional components.  |

# ProgDefGroupType

The **ProgDefGroupType** function sets the value of the ALLUSERS system variable. For more details, see [ALLUSERS](#).

## Syntax

```
ProgDefGroupType ( nType );
```

## Parameters

**Table 141** ▪ ProgDefGroupType Parameters

| Parameter | Description                                                                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nType     | Specifies the value to use for the InstallScript variable ALLUSERS. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li><b>PERSONAL</b>—Set ALLUSERS equal to FALSE.</li> <li><b>COMMON</b>—Set ALLUSERS equal to TRUE.</li> </ul> |

## Return Values

**Table 142** ▪ ProgDefGroupType Return Values

| Return Value | Description                        |
|--------------|------------------------------------|
| 0            | This function always returns zero. |

# Built-In Functions (Q-R)

For a list of functions by category, see [Built-In Functions by Category](#).

## QueryProgItem

The [GetShortcutInfo](#) function supersedes the **QueryProgItem** function.

The **QueryProgItem** function checks for the existence of a specific program item or subfolder name. If the InstallScript engine finds the item or subfolder, **QueryProgItem** returns its attributes. The attributes include the product's command line, working directory, icon path, shortcut key, and minimize flag.

To use **QueryProgItem**, enter information in the parameters szFolderName and szItemName. The InstallScript engine fills the remaining parameters with the program item's attributes.

### Syntax

```
QueryProgItem ( szFolderName, szItemName, svCmdLine, svWrkDir, svIconPath, nvIconIndex, svShortCutKey,  
               nvMinimizeFlag );
```

## Parameters

**Table 1** • QueryProgItem Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFolderName</b>  | <p>Specifies the name of the folder that contains the item or subfolder. You can specify a fully qualified path for szFolderName, such as:</p> <pre>"C:\\ProgramData\\Microsoft\\Windows\\Start Menu\\Programs\\Games"</pre> <p>If szFolderName is null, <b>QueryProgItem</b> searches the default Programs directory. If you do not specify an absolute path (a path that includes a drive specification, for example, "C:\\Program Files\\AppName") for szFolderName, <b>QueryProgItem</b> searches for a subfolder under the default Programs directory; the location depends on the value of the InstallScript variable ALLUSERS, as well as the version of Windows on the target system.</p> <p>You can also use an InstallScript system variable:</p> <ul style="list-style-type: none"> <li>• <b>FOLDER_DESKTOP</b>—Queries items in the Desktop folder.</li> <li>• <b>FOLDER_STARTUP</b>—Queries items in the Startup menu.</li> <li>• <b>FOLDER_STARTMENU</b>—Queries items in the Start menu.</li> <li>• <b>FOLDER_PROGRAMS</b>—Queries items in the Start\\Programs menu.</li> </ul> <p>Or you could use a relative path, such as:</p> <pre>FOLDER_PROGRAMS ^ "ACCESSORIES\\GAMES"</pre> |
| <b>szItemName</b>    | Specifies the name of the program item or subfolder to find.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>svCmdLine</b>     | Returns either the command line of the item's executable file or the complete path to the subfolder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>svWrkDir</b>      | Returns the full path of the working directory of the program item. (Not applicable if szItemName is a subfolder.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>svIconPath</b>    | Returns the fully qualified file name of the .ico file or .exe file. (Not applicable if szItemName is a subfolder.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>nvIconIndex</b>   | Returns the index of the icon used for the program item. (Not applicable if szItemName is a subfolder.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>svShortCutKey</b> | Returns the item's shortcut key. (Not applicable if szItemName is a subfolder.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**Table 1** ▪ QueryProgItem Parameters (cont.)

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvMinimizeFlag</b> | <p>(Not applicable if szItemName is a subfolder.) Returns one of the following constants, indicating whether an application window is minimized when first displayed:</p> <ul style="list-style-type: none"> <li>● <b>NULL</b>—Indicates that the application's window is not minimized upon startup.</li> <li>● <b>RUN_MINIMIZED</b>—Indicates that the application's window is minimized upon startup.</li> </ul> |

## Return Values

**Table 2** ▪ QueryProgItem Return Values

| Return Value         | Description                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IS_ITEM (0)</b>   | Indicates szItemName is a program item or shortcut in szFolderName.                                                                                                                                                                                         |
| <b>IS_FOLDER (1)</b> | Indicates szItemName is a subfolder in szFolderName.                                                                                                                                                                                                        |
| <b>&lt; 0</b>        | <p>Indicates that the function was unable to find the program item or subfolder name.</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <b>FormatMessage</b>.</p> |

## Additional Information

The location of the Start menu is different under different languages. The InstallScript engine automatically selects the correct path.

## QueryProgItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the QueryProgItem function.
*
* QueryProgItem is called to find the attributes of a target
* file or folder.
*
* Note: Before running this script, set the defined constants
*       FOLDER_NAME and ITEM_NAME so that they reference an

```

```

*      existing folder name and folder item.
*
\*-----*/
// Define constants to reference the file or folder name.
#define FOLDER_NAME  "C:\\Windows\\Start Menu\\Programs"
#define ITEM_NAME    "InstallShield"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_QueryProgItem(HWND);

function ExFn_QueryProgItem(hMSI)
    STRING    svCmdLine, svWrkDir, svIconPath;
    STRING    svShortCutKey, svGroupPath, szTitle, szMsg, szInfo, svMinFlag;
    STRING    svMinimizeFlag;
    NUMBER    nvIconIndex, nvMinimizeFlag, nResult, nvMinFlag;
    LIST      listInfo, listID;
begin

    // Search for an item in the FOLDER_NAME folder.
    nResult = QueryProgItem (FOLDER_NAME, ITEM_NAME, svCmdLine, svWrkDir,
                            svIconPath, nvIconIndex, svShortCutKey,
                            nvMinimizeFlag);

    // Create string list.
    listInfo = ListCreate (STRINGLIST);

    // Error check QueryProgItem.
    if (nResult < 0) then
        // Report the error; then abort.
        MessageBox("QueryProgItem failed.", SEVERE);
        abort;
    // Check if the item is an application.
    elseif (nResult = IS_ITEM) then
        // Add the command line to the string list.
        Sprintf(szInfo, "The command line of %s: %s", ITEM_NAME, svCmdLine);
        ListAddString(listInfo, szInfo, AFTER);

        // Add the working directory to string list.
        Sprintf(szInfo, "The working directory of %s: %s", ITEM_NAME, svWrkDir);
        ListAddString(listInfo, szInfo, AFTER);

        // Add the icon path to string list.
        Sprintf(szInfo, "The icon path of %s: %s", ITEM_NAME, svIconPath);
        ListAddString(listInfo, szInfo, AFTER);

        // Add icon index to string list.
        Sprintf(szInfo, "The index of the icon: %d", nvIconIndex);
        ListAddString(listInfo, szInfo, AFTER);

        // Add shortcut key to string list.
        Sprintf (szInfo, "The shortcut key of %s: %s", ITEM_NAME,
                svShortCutKey);
        ListAddString(listInfo, szInfo, AFTER);

```

```

        // Check if the item is a folder.
    elseif (nResult = IS_FOLDER) then
        // Add a message to string list.
        Sprintf (szInfo, "The item is a subfolder. QueryProgItem does not " +
            "retrieve very much information about subfolders.");
        ListAddString(listInfo, szInfo, AFTER);
    endif;

    // Display the string list.
    szTitle = "QueryProgItem Example";
    szMsg   = "The following are attributes of the item:";
    SdShowInfolist(szTitle, szMsg, listInfo);

    // Destroy the list.
    ListDestroy (listID);

end;

```

## QueryShellMgr

The **QueryShellMgr** function obtains the name of the program shell being used by Microsoft Windows. For example, if the program shell is Explorer, QueryShellMgr returns the string "Explorer.exe" in svShellMgrName.

### Syntax

```
QueryShellMgr ( svShellMgrName );
```

## Parameters

**Table 3** • QueryShellMgr Parameters

| Parameter             | Description                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>svShellMgrName</b> | Returns the unqualified name (that is, without the drive designation or path) of the shell manager that is currently running. |

## Return Values

**Table 4** • QueryShellMgr Return Values

| Return Value  | Description                                                                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully retrieved the name of the program shell.                                                                                                                                                                             |
| <b>&lt; 0</b> | Indicates that the function was unable to retrieve the name of the program shell.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

If the shell on the target system is not Explorer, you may need to launch that shell with the [LaunchApp](#) function. The InstallScript functions that create program folders and program icons use a DDE conversation with the shell to create the program folders and program items. Most alternate shells such as the Norton Desktop emulate the Explorer shell. Therefore, they can create program folders and items.

In shells that do not emulate the Explorer shell, InstallShield cannot use the program folder and program item functions to create or modify the program folders and program items. Check with the manufacturer of the shell to determine how it handles the creation of program folders and program items using Microsoft DDE specifications.

## QueryShellMgr Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the QueryShellMgr function.
*
```

```

* QueryShellMgr is called to find the name of the shell
* manager. The name is then displayed in a message box.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_QueryShellMgr(HWND);

function ExFn_QueryShellMgr(hMSI)
    STRING svShellMgrName, szTitle, szMsg;
    NUMBER nReturn;
begin

    // Get the name of the program shell.
    nReturn = QueryShellMgr (svShellMgrName);

    if (nReturn < 0) then
        // Report an error.
        MessageBox ("Could not retrieve the program shell.", SEVERE);
    else
        // Display the name of the shell.
        MessageBox ("The shell manager is " + svShellMgrName + ".", INFORMATION);
    endif;

end;

```

## ReadArrayProperty

**Project** - This information applies to InstallScript projects.

The **ReadArrayProperty** function is called in an object script to read the value of a specified property whose value is an array.

### Syntax

```
ReadArrayProperty ( nPropertyBag, szPropertyName, ArrayPointer );
```

## Parameters

**Table 5** • ReadArrayProperty Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nPropertyBag</b>   | Specifies a reference to the object's property bag object, in which property values are stored. (The value of nPropertyBag is passed by the setup engine to the ReadProperties function block within which ReadBoolProperty is called. This value is placed in the object script when you use the Add New Property dialog in the InstallScript view.) |
| <b>szPropertyName</b> | Specifies the name of the property whose value you want to read.                                                                                                                                                                                                                                                                                      |
| <b>ArrayPointer</b>   | Returns a pointer to the specified array property.                                                                                                                                                                                                                                                                                                    |

## Return Values

**Table 6** • ReadArrayProperty Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| <b>0</b>     | This function always returns zero (0). |

# ReadBoolProperty

**Project** • This information applies to InstallScript projects.

The **ReadBoolProperty** function is called in an object script to read the value of a specified property whose value is a Boolean.

## Syntax

```
ReadBoolProperty ( nPropertyBag, szPropertyName, bvPropertyValue );
```

## Parameters

**Table 7** • ReadBoolProperty Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nPropertyBag</b>    | Specifies a reference to the object's property bag object, in which property values are stored. (The value of nPropertyBag is passed by the setup engine to the ReadProperties function block within which ReadBoolProperty is called. This value is placed in the object script when you use the Add New Property dialog in the InstallScript view.) |
| <b>szPropertyName</b>  | Specifies the name of the property whose value you want to read.                                                                                                                                                                                                                                                                                      |
| <b>bvPropertyValue</b> | Returns the value of the specified property.                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 8** • ReadBoolProperty Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| <b>0</b>     | This function always returns zero (0). |

# ReadBytes

The **ReadBytes** function reads a specific number of bytes from a file starting at the current file pointer location. When this function returns, InstallShield relocates the file pointer to the new position at the end of the bytes read from the file.

**Note** • Before you can read from the file, which may be a file on the Internet, you must open the file in binary mode by calling [OpenFileMode](#) and [OpenFile](#).

The parameter nIndex is an index into the value specified by svString. Use the parameter nBytes to specify how many bytes beyond the parameter nIndex to read from the file. If the nIndex plus nBytes is a value larger than the length of the svString, only the number of bytes from the index of the string to the end of the string are read from the file. For example, if svString is declared to be 100 bytes long, the parameter nIndex is declared as 50 bytes and the parameter nBytes is 75 bytes, only the bytes between 49 and 99 (50 bytes instead of 75 bytes) are read.

## Syntax

```
ReadBytes ( nFileHandle, svString, nIndex, nBytes );
```

## Parameters

**Table 9** ▪ ReadBytes Parameters

| Parameter          | Description                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nFileHandle</b> | Specifies the file handle to a file opened in binary mode.                                                                                                                                                     |
| <b>svString</b>    | Returns the bytes read from the file. The variable passed in this parameter must have been declared with an explicit size, and it must be large enough to accommodate the number of bytes specified by nBytes. |
| <b>nIndex</b>      | Specifies an index into svString; data from the file is inserted into the string at this location.                                                                                                             |
| <b>nBytes</b>      | Specifies the number of bytes to read from the file. Bytes are read starting from the current location of the file pointer. InstallShield relocates the file pointer as the bytes are read.                    |

## Return Values

**Table 10** ▪ ReadBytes Return Values

| Return Value  | Description                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>X</b>      | Indicates that the function successfully read bytes from the file, where X is the actual number of bytes returned in svString. |
| <b>&lt; 0</b> | Indicates that the function was unable to successfully read from the file.                                                     |

## ReadBytes Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ReadBytes and SeekBytes functions.
*
* SeekBytes is called to position a file pointer to a
```

```

* specific location in a file that has been opened in binary
* mode. ReadBytes then reads a specific number of bytes,
* starting at this location. The bytes are read into a string,
* which is then displayed in a message box.
*
* Note: The defined constants EXAMPLE_DIR and EXAMPLE_BIN must
*       be set to an existing directory and file on the target
*       system.
*
\*-----*/

#define EXAMPLE_DIR "C:\\\"
#define EXAMPLE_BIN "Example.bin"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ReadBytes(HWND);

function ExFn_ReadBytes(hMSI)
    STRING svString;
    NUMBER nvFileHandle;
begin

    // Set the file mode to read/write.
    OpenFileMode (FILE_MODE_BINARY);

    // Open a binary file.
    if (OpenFile (nvFileHandle, EXAMPLE_DIR, EXAMPLE_BIN) < 0) then
        // Report an error; then abort.
        SprintfBox (SEVERE, "CopyBytes Example", "Could not open %s.",
                    EXAMPLE_BIN);
        abort;
    endif;

    // Set the file pointer to the 16th byte in the file.
    SeekBytes (nvFileHandle, 15, FILE_BIN_START);

    // Read the next twenty-eight bytes into svString.
    if (ReadBytes (nvFileHandle, svString, 0, 28) < 0) then
        // Report an error.
        MessageBox ("ReadBytes failed.", SEVERE);
    else
        // Display the string.
        SprintfBox (INFORMATION, "ReadBytes Example", "Bytes read: %s",
                    svString);
    endif;

    // Close the file.
    CloseFile (nvFileHandle);

end;

```

# ReadNumberProperty

**Project** ▪ This information applies to InstallScript projects.

The **ReadNumberProperty** function is called in an object script to read the value of a specified property whose value is a number.

## Syntax

```
ReadNumberProperty ( nPropertyBag, szPropertyName, nvPropertyValue );
```

## Parameters

**Table 11** ▪ ReadNumberProperty Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nPropertyBag</b>    | Specifies a reference to the object's property bag object, in which property values are stored. (The value of nPropertyBag is passed by the setup engine to the ReadProperties function block within which ReadBoolProperty is called. This value is placed in the object script when you use the Add New Property dialog in the InstallScript view.) |
| <b>szPropertyName</b>  | Specifies the name of the property whose value you want to read.                                                                                                                                                                                                                                                                                      |
| <b>nvPropertyValue</b> | Returns the value of the specified property.                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 12** ▪ ReadNumberProperty Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| 0            | This function always returns zero (0). |

# ReadStringProperty

**Project** ▪ This information applies to InstallScript projects.

The **ReadStringProperty** function is called in an object script to read the value of a specified property whose value is a string.

## Syntax

```
ReadStringProperty ( nPropertyBag, szPropertyName, svPropertyValue );
```

## Parameters

**Table 13** • ReadStringProperty Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nPropertyBag</b>    | Specifies a reference to the object's property bag object, in which property values are stored. (The value of nPropertyBag is passed by the setup engine to the ReadProperties function block within which ReadBoolProperty is called. This value is placed in the object script when you use the Add New Property dialog in the InstallScript view.) |
| <b>szPropertyName</b>  | Specifies the name of the property whose value you want to read.                                                                                                                                                                                                                                                                                      |
| <b>svPropertyValue</b> | Returns the value of the specified property.                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 14** • ReadStringProperty Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| <b>0</b>     | This function always returns zero (0). |

# RebootDialog

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **RebootDialog** function displays a message box that enables end users to specify whether they want to restart the computer. The selected option is performed at the end of the installation.

When you call a function with the SHAREDFILE or LOCKEDFILE option and locked .dll or .exe files are encountered, updated versions of the locked files are copied to the target system and the system variable BATCH\_INSTALL is set to TRUE. **RebootDialog** automatically commits the locked files for update when the system is restarted, unless the user selects the **No, I will restart my computer later** option.

The InstallScript engine makes every attempt not to restart the system when other instances of the installation are running. Because of this, you must make sure all other instances of the installation are shut down before calling **RebootDialog**. Your message to end users should request that they ensure all other applications are shut down before restarting the system.

**Note** • An alternative to the **RebootDialog** function is *SdFinishReboot*, which has a better look and feel than the **RebootDialog** dialog.

## Syntax

```
RebootDialog ( szTitle, szMsg, nDefChoice );
```

## Parameters

**Table 15** • RebootDialog Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title Restarting Windows, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                           |
| <b>szMsg</b>      | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                          |
| <b>nDefChoice</b> | Specifies the default option button selection. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>SYS_BOOTMACHINE</b>—The option to reboot the computer (Yes, I want to restart my computer now) is the default option button selection.</li> <li>• <b>0</b>—The option to not restart the computer (No, I will restart my computer later) is the default option button selection.</li> </ul> |

## Return Values

**Table 16** • RebootDialog Return Values

| Return Value       | Description                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>WILL_REBOOT</b> | Indicates that the end user selected the Yes, I want to restart my computer now option button. |
| <b>0</b>           | Indicates that the end user selected the No, I will restart my computer later option button.   |

## Additional Information

The message box that is displayed by the **RebootDialog** function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## RebootDialog Example

**Project** - This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the RebootDialog function.
 *
 * This script calls RebootDialog to display a dialog that
 * asks the user whether or not to reboot the computer. The call
 * to RebootDialog passes a null string in parameter 2 to display
 * the default message and 0 in parameter 3 to make the default
 * selection "No, I will restart my computer later."
 *
 * Warning: If the end user selects Yes in this dialog, the
 *         computer is rebooted.
 *
 \*-----*/

#define TITLE_TEXT "RebootDialog Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_RebootDialog(HWND);

function ExFn_RebootDialog(hMSI)
    NUMBER nvDefChoice;
begin

    // Query to reboot computer.
    RebootDialog (TITLE_TEXT, "", 0);

end;
```

## RegDBConnectRegistry

**Project** - For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBConnectRegistry** function creates a connection to a remote registry. After you have opened the connection, you can create, delete, or retrieve registry keys, value names, and value pairs on a remote registry much as you would on a local registry. This functionality is also supported on 64-bit systems with some [limitations](#).

---

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

`RegDBConnectRegistry` allows you to edit only one registry root key each time the remote registry is opened, and you can edit only keys and values under either `HKEY_LOCAL_MACHINE` or `HKEY_USERS`. When you call `RegDBConnectRegistry`, you must specify which root key you want to be able to edit. If you want to edit the other root key or one its subkeys, you must close and re-open the connection.

---

**Caution** ▪ Because you set the root key by calling `RegDBConnectRegistry`, you cannot call `RegDBSetDefaultRoot` after you have established a connection to a remote registry. When you call `RegDBDisconnectRegistry`, all calls to registry-related functions affect the local registry, and you can then call `RegDBSetDefaultRoot` to change the root key.

---

**Note** ▪ If you are trying to open a registry on a remote Windows system, you must have administrator privileges. This function is intended for use by system administrators for network installations.

## Syntax

```
RegDBConnectRegistry ( szRemoteSystem, nKeyType, nReserved );
```

## Parameters

**Table 17** ▪ RegDBConnectRegistry Parameters

| Parameter             | Description                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szRemoteSystem</b> | Specifies the name of the system with which to connect, such as "RemoteSys". If you pass a null string ("") in this parameter, the function creates a connection to the local registry. |
| <b>nKeyType</b>       | Specifies one of the following constants: HKEY_LOCAL_MACHINE or HKEY_USERS.                                                                                                             |
| <b>nReserved</b>      | Pass zero in this parameter. No other value is allowed.                                                                                                                                 |

## Return Values

**Table 18** ▪ RegDBConnectRegistry Return Values

| Return Value                            | Description                                                                                                                                                                             |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>                                | Indicates this function successfully established a connection to the system registry.                                                                                                   |
| <b>REGDB_ERR_CONNECTIONEXISTS (-6)</b>  | A connection to a remote registry already exists. It must be closed using RegDBDisconnectRegistry before you can call RegDBConnectRegistry again.                                       |
| <b>REGDB_ERR_CORRUPTEDREGISTRY (-4)</b> | Indicates that the remote registry is corrupted and cannot be accessed.                                                                                                                 |
| <b>REGDB_ERR_INITIALIZATION (-2)</b>    | Indicates that the registry services could not be initialized. Make sure Remote Administration is enabled and that you have appropriate privileges to be able to write to the registry. |
| <b>REGDB_ERR_INVALIDHANDLE (-5)</b>     | The key name provided for the remote registry is not allowed.                                                                                                                           |
| <b>REGDB_ERR_INVALIDNAME (-3)</b>       | Indicates that the system in szRemoteSystem could not be found. Check the name and try again.                                                                                           |
| <b>-1</b>                               | Other error.                                                                                                                                                                            |

You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling [FormatMessage](#).

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the REGISTRYFUNCTIONS\_USETEXTSUBS argument.

## RegDBConnectRegistry Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBConnectRegistry function and
* RegDBDisconnectRegistry function.
*
* Note: In order for this script to run properly, you must set
*       the preprocessor constants to a valid remote computer
*       with remote administration enabled. Both computers
*       must also have the remote-registry service enabled.
*
\*-----*/

#define REMOTE "IShield_NT1"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBConnectRegistry(HWND);

function ExFn_RegDBConnectRegistry(hMSI)
    STRING szRemoteMachine, szKey, szTitle, szMsg;
    NUMBER nKeyType, nReturn;

    // will now alter only the local registry.
    nReturn = RegDBDisconnectRegistry(0);

    if (nReturn < 0) then
        MessageBox("RegDBDisconnectRegistry failed.\n\nRemote registry still " +
            "connected.", SEVERE);
    else
        MessageBox("RegDBDisconnectRegistry successful.\n\nRemote registry " +
            "disconnected.", INFORMATION);
    endif;

end;

```

# RegDBCopyKeys

---

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBCopyKeys** function copies the registry keys and values under the key specified by szSourceKey to the key specified by szTargetKey.

---

**Note** ▪ This function supports the 64-bit parts of the registry by using the REGDB\_OPTION\_WOW64\_64KEY option. For more information, see [REGDB\\_OPTIONS](#).

## Syntax

```
RegDBCopyKeys ( szSourceKey, szTargetKey, nRootKeySource, nRootKeyTarget );
```

## Parameters

**Table 19** ▪ RegDBCopyKeys Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSourceKey</b>    | Specifies the name of the key whose subkeys and values are to be copied. Separate different levels in the subkey with a double backslash (\\).                                                                                                                                                                                                                   |
| <b>szTargetKey</b>    | Specifies the name of the key to be copied to. Separate different levels in the subkey with a double backslash (\\). If this key does not exist, RegDBCopyKeys creates it. If this key does exist, any existing values under the key that have the same names as values under szSourceKey are overwritten; this includes values under identically named subkeys. |
| <b>nRootKeySource</b> | Specifies the root key of szSourceKey. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• HKEY_CLASSES_ROOT</li> <li>• HKEY_CURRENT_USER</li> <li>• HKEY_LOCAL_MACHINE</li> <li>• HKEY_USERS</li> <li>• HKEY_CURRENT_CONFIG</li> <li>• HKEY_DYN_DATA</li> </ul>                                          |
| <b>nRootKeyTarget</b> | Specifies the root key of szTargetKey. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• HKEY_CLASSES_ROOT</li> <li>• HKEY_CURRENT_USER</li> <li>• HKEY_LOCAL_MACHINE</li> <li>• HKEY_USERS</li> <li>• HKEY_CURRENT_CONFIG</li> <li>• HKEY_DYN_DATA</li> </ul>                                          |

## Return Values

**Table 20** ▪ RegDBCopyKeys Return Values

| Return Value               | Description                                                                                                                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully copied the keys and values.                                                                                                                                                                           |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to copy the keys and values.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891(0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the `REGISTRYFUNCTIONS_USETEXTSUBS` argument.

# RegDBCopyValues

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBCopyValues** function copies the registry values under the key specified by `szSourceKey` to the key specified by `szTargetKey`.

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

## Syntax

```
RegDBCopyValues ( szSourceKey, szTargetKey, nRootKeySource, nRootKeyTarget );
```

## Parameters

**Table 21** • RegDBCpyValues Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSourceKey</b>    | Specifies the name of the key whose values are to be copied. Separate different levels in the subkey with a double backslash (\\).                                                                                                                                                                                      |
| <b>szTargetKey</b>    | Specifies the name of the key to be copied to. Separate different levels in the subkey with a double backslash (\\). If this key does not exist, RegDBCpyKeys creates it. If this key does exist, any existing values under the key that have the same names as values under szSourceKey are overwritten.               |
| <b>nRootKeySource</b> | Specifies the root key of szSourceKey. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• HKEY_CLASSES_ROOT</li> <li>• HKEY_CURRENT_USER</li> <li>• HKEY_LOCAL_MACHINE</li> <li>• HKEY_USERS</li> <li>• HKEY_CURRENT_CONFIG</li> <li>• HKEY_DYN_DATA</li> </ul> |
| <b>nRootKeyTarget</b> | Specifies the root key of szTargetKey. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• HKEY_CLASSES_ROOT</li> <li>• HKEY_CURRENT_USER</li> <li>• HKEY_LOCAL_MACHINE</li> <li>• HKEY_USERS</li> <li>• HKEY_CURRENT_CONFIG</li> <li>• HKEY_DYN_DATA</li> </ul> |

## Return Values

**Table 22** • RegDBCpyValues Return Values

| Return Value               | Description                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully copied the values.                                                                                                                                                                            |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to copy the values.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the `REGISTRYFUNCTIONS_USETEXTSUBS` argument.

# RegDBCreateKeyEx

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBCreateKeyEx** function creates a key in the registry. You can also associate a class object with the newly created key (advanced users only). The newly created key does not have a value associated with it.

When logging is enabled, the InstallScript engine logs each key in the path that is passed through `szKey` to **RegDBCreateKeyEx**. For example, you might pass the following for `szKey`:

**"Software" ^ IFX\_COMPANY\_NAME ^ IFX\_PRODUCT\_NAME**

In this case, the InstallScript engine logs several keys:

- Software
- The value of the `IFX_COMPANY_NAME` variable
- The value of the `IFX_PRODUCT_NAME` variable

The log flags a key as “created” if it did not already exist. In the aforementioned example, the Software key already exists on all target systems (`HKEY_LOCAL_MACHINE` or `HKEY_CURRENT_USER`). The Software key is logged, but its “created” flag would be false, indicating that the key should not be removed during uninstallation. Any keys that are created and logged (because they did not already exist at the time the installation was running) are removed during uninstallation.

When a key is uninstalled, all of its subkeys are also uninstalled. Therefore, if you use **RegDBCreateKeyEx** to create a key or keys under a key that is already logged for uninstallation, the keys that you create will be uninstalled when the higher-level key is uninstalled. This behavior occurs regardless of whether logging is enabled when the installation creates your keys and regardless of the order in which the installation creates the keys. Therefore, in the aforementioned example, if logging is also enabled for a second installation that likewise uses **RegDBCreateKeyEx** to create a key for a different product under the `IFX_COMPANY_NAME` key that the first installation created, and the then end user uninstalls the first product, the entire `IFX_COMPANY_NAME` key, with both of the product subkeys, are removed. This may make the second product behave unexpectedly.

If you want to be able to share registry keys among multiple installations, it is recommended that you use the Registry view to configure the registry entries, instead of using the **RegDBCreateKeyEx** function. In the Registry view of an InstallScript project, you can mark a registry keys as shared (by right-clicking the key and then clicking **Shared among several applications**). During the uninstallation, the InstallScript engine removes a shared key only if no other logged installations that share the key still exist on the machine.

To view all of the registry keys that were logged during an installation and find out how each of their “created” flags were set, use the InstallShield Cabinet and Log File Viewer.

For more information about logging, see [InstallScript Functions that Are Logged for Uninstallation](#).

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

### Syntax

```
RegDBCreateKeyEx ( szKey, szClass );
```

### Parameters

**Table 23** ▪ RegDBCreateKeyEx Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>   | Specify the name of the key to create. Separate different levels in the subkey with a double backslash (\\).<br><br>If the root key is <code>HKEY_CLASSES_ROOT</code> , you do not need to specify the <code>HKEY_CLASSES_ROOT</code> in this parameter. Unless you specify otherwise, the InstallScript engine creates the key as a subkey of <code>HKEY_CLASSES_ROOT</code> . To specify a different root key, you can call <a href="#">RegDBSetDefaultRoot</a> before calling <b>RegDBCreateKeyEx</b> . |
| <b>szClass</b> | Specify the class name to associate with this key.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Return Values

**Table 24** ▪ RegDBCreateKeyEx Return Values

| Return Value  | Description                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully created the subkey.                                                                                                                                                                             |
| <b>&lt; 0</b> | Indicates that the function was unable to create the subkey.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

### Additional Information

**RegDBCreateKeyEx** is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions. For more information on special registry-related functions, see [Special Registry-Related Functions](#).

**Note** ▪ Windows does not allow the creation of a key directly under `HKEY_LOCAL_MACHINE` or `HKEY_USERS`.

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the `REGISTRYFUNCTIONS_USETEXTSUBS` constant.

## RegDBCreateKeyEx Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBCreateKeyEx and RegDBKeyExist functions.
*
* First, RegDBCreateKeyEx is called to create a subkey with no
* class value in the HKEY_CLASSES_ROOT key. Then, RegDBKeyExist
* is then called to check if the key was created.
*
* RegDBCreateKeyEx is called again to create a multi-level subkey
* with a class value associated with it under HKEY_CLASSES_ROOT.
* Then RegDBKeyExist is called again to check for the existence
* of the new key.
*
\*-----*/

#define TITLE_TEXT "RegDBCreateKeyEx & RegDBKeyExist"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBCreateKeyEx(HWND);

function ExFn_RegDBCreateKeyEx(hMSI)
    STRING szKey, szClass, szKeyRoot, szMsg, svLogFile;
    NUMBER nResult1, nResult2;
begin
    // Create a key with no class value.
    szKey = "CreateKeyExample";
    szClass = "";

    if (RegDBCreateKeyEx(szKey, szClass) < 0) then
        MessageBox ("First call to RegDBCreateKeyEx failed.", SEVERE);
        abort;
    else
        sprintfBox (INFORMATION, TITLE_TEXT, "Successfully created: %s", szKey);

        // Check to see if the key just created exists.
        if (RegDBKeyExist (szKey) < 0) then
            MessageBox ("First call to RegDBKeyExist failed.", SEVERE);
        else
```

```

        SprintfBox (INFORMATION, TITLE_TEXT, "%s exists.", szKey);
    endif;
endif;

if (RegDBDeleteKey (szKey) < 0) then
    MessageBox ("RegDBDeleteKey failed.", SEVERE);
endif;

// Create a key with more than one sublevel and a class value.
szKey      = "ShareWare\\Games\\CoolChess";
szClass    = "LastPlayed";
szKeyRoot = "ShareWare";

if (RegDBCreateKeyEx(szKey, szClass) < 0) then
    MessageBox ("Second call to RegDBCreateKeyEx failed.", SEVERE);
    abort;
else
    SprintfBox (INFORMATION, TITLE_TEXT, "Successfully created: %s", szKey);

    // Check if the newly created multi-level key exists.
    if (RegDBKeyExist (szKeyRoot) < 0) then
        MessageBox ("Second call to RegDBKeyExist failed.", SEVERE);
    else
        SprintfBox (INFORMATION, TITLE_TEXT, "%s exists.", szKey);
    endif;
endif;

if (RegDBDeleteKey (szKey) < 0) then
    MessageBox ("RegDBDeleteKey failed.", SEVERE);
endif;

end;

```

## RegDBDeleteItem

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

**RegDBDeleteItem** is a special registry-related function designed to work with certain predefined registry keys. The **RegDBDeleteItem** function deletes values under the per application paths key or the application uninstallation key, depending on the value of `nItem`. Calling **RegDBDeleteItem** with either the `REGDB_APPPATH` or the `REGDB_APPPATH_DEFAULT` option results in the deletion of the per application paths key.

**Note** ▪ The InstallScript engine currently does not support writing or reading Add or Remove Programs information for a product in the 64-bit part of the registry. Therefore, using the `REGDB_OPTION_WOW64_64KEY` option with the `REGDB_OPTIONS` system variable is not supported for this registry function. Enabling the `REGDB_OPTION_WOW64_64KEY` option has no effect on where registry entries are created by this function.

## Syntax

```
RegDBDeleteItem( nItem );
```

## Parameters

**Table 25** • RegDBDeleteItem Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nItem</b> | <p>Specifies the item to delete. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>REGDB_APPPATH</b>—The data of the Path value under the per-application paths key. This key is deleted by the installation as a result of calling <b>CreateInstallationInfo</b>. You must call <b>CreateInstallationInfo</b> to create this key before calling <b>RegDBDeleteItem</b>. (In an event-based script, <b>CreateInstallationInfo</b> is called in the default <b>OnMoveData</b> event handler code.)</li> <li>• <b>REGDB_APPPATH_DEFAULT</b>—The data of the DefaultPath value under the per-application paths key. This key is created by the installation as a result of calling <b>CreateInstallationInfo</b>. You must call <b>CreateInstallationInfo</b> to create this key before calling <b>RegDBDeleteItem</b>. (In an event-based script, <b>CreateInstallationInfo</b> is called in the default <b>OnMoveData</b> event handler code.)</li> <li>• <b>REGDB_UNINSTALL_COMMENTS</b>—The data of the Comments value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_CONTACT</b>—The data of the Contact value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_DISPLAY_VERSION</b>—The data of the DisplayVersion value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_DISPLAYICON</b>—The data of the DisplayIcon value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_HELPLINK</b>—The data of the HelpLink value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_HELPTELEPHONE</b>—The data of the HelpTelephone value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_INSTALLDATE</b>—The data of the InstallDate value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_INSTALLLOC</b>—The data of the InstallLocation value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_INSTALLSOURCE</b>—The data of the InstallSource value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_LANGUAGE</b>—The data of the Language value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_LOGFILE</b>—The data of the LogFile value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_MAINT_OPTION</b>—The data of the LogMode value under the uninstallation key.</li> </ul> |

**Table 25** ▪ RegDBDeleteItem Parameters (cont.)

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>nItem<br/>(cont.)</b> | <ul style="list-style-type: none"> <li>• <b>REGDB_UNINSTALL_STRING</b>—The data of the UninstallString value under the uninstallation key. The UninstallString value is created when the <b>MaintenanceStart</b> or <b>DeinstallStart</b> functions are called.</li> <li>• <b>REGDB_UNINSTALL_SYSTEMCOMPONENT</b>—The data of the SystemComponent value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_URLINFOABOUT</b>—The data of the URLInfoAbout value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_URLUPDATEINFO</b>—The data of the URLUpdateInfo value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_VERSION</b>—The data of the Version value under the uninstallation key. When this constant is used, szValue specifies the installed product's version number expressed as a string, for example, "16777216".</li> </ul> |
|                          |  <p><b>Important</b> ▪ Do not use <b>REGDB_WINCURREVER_REGOWNER</b> or <b>REGDB_WINCURREVER_REGORGANIZATION</b> with this function. Windows sets these values, and they should not be deleted by an installation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Return Values

**Table 26** • RegDBDeleteItem Return Values

| Return Value  | Description                                             |
|---------------|---------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully set the value. |
| <b>&lt; 0</b> | Indicates that the function failed.                     |

## Additional Information

- By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the **REGISTRYFUNCTIONS\_USETEXTSUBS** argument.
- **RegDBDeleteItem** does not write anything to the uninstall log file; thus, calling this function does not have any effect how the application is uninstalled.

# RegDBDeleteKey

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBDeleteKey** function deletes a specific key and its associated value from the registry. All subkeys of the deleted key are also deleted, along with their associated values.

InstallShield assumes the key specified in `szSubKey` is a subkey of `HKEY_CLASSES_ROOT`. You can use `RegDBSetDefaultRoot` to specify another root key.

`RegDBDeleteKey` is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions. For more information on special registry-related functions, see [Special Registry-Related Functions](#).

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

## Syntax

```
RegDBDeleteKey ( szSubKey );
```

## Parameters

**Table 27** ▪ RegDBDeleteKey Parameters

| Parameter       | Description                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------|
| <b>szSubKey</b> | Specifies the name of the key to delete. Separate different levels in the subkey with a double backslash (\\). |

## Return Values

**Table 28** ▪ RegDBDeleteKey Return Values

| Return Value  | Description                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully deleted the key.                                                                                                                                                                             |
| <b>&lt; 0</b> | Indicates that the function was unable to delete the key.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

- By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the `REGISTRYFUNCTIONS_USETEXTSUBS` argument.
- RegDBDeleteKey** does not write anything to the uninstall log file; thus, calling this function does not have any effect how the application is uninstalled.

## RegDBDeleteKey Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBDeleteKey function.
*
* This example creates and then deletes a registry key.
* Almost all of the examples provided with the registry functions
* use this function to delete a key. Please refer to those
* examples for more information.
*
\*-----*/
```

```

#define TITLE_TEXT "RegDBDeleteKey Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBDeleteKey(HWND);

function ExFn_RegDBDeleteKey(hMSI)
    STRING szKey, szClass, szKeyRoot, szMsg, svLogFile;
    NUMBER nResult1, nResult2;
begin

    // Set up parameters for call to RegDBCreateKeyEx.
    szKey = "DeleteMeKey";
    szClass = "";

    // Create a key with no class value.
    if (RegDBCreateKeyEx (szKey, szClass) < 0) then
        MessageBox ("RegDBCreateKeyEx failed.", SEVERE);
        abort;
    else
        sprintfBox (INFORMATION, TITLE_TEXT, "%s successfully created.", szKey);
    endif;

    // Call RegDBDeleteKey to delete the key just created.
    if (RegDBDeleteKey (szKey) < 0) then
        MessageBox ("RegDBDeleteKey failed.", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE_TEXT, "%s successfully deleted.", szKey);
    endif;

end;

```

## RegDBDeleteValue

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBDeleteValue** function deletes a value from a specific key in the registry. InstallShield assumes that the key specified in szSubKey is a subkey of HKEY\_CLASSES\_ROOT. You must use RegDBSetDefaultRoot to specify another root key.

RegDBDeleteKey is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions. For more information on special registry-related functions, see [Special Registry-Related Functions](#).

**Note** ▪ This function supports the 64-bit parts of the registry by using the REGDB\_OPTION\_WOW64\_64KEY option. For more information, see [REGDB\\_OPTIONS](#).

## Syntax

```
RegDBDeleteValue ( szSubKey, szValue );
```

## Parameters

**Table 29** ▪ RegDBDeleteValue Parameters

| Parameter       | Description                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSubKey</b> | Specifies the name of the registry key that contains the value name to delete. Separate different levels in the subkey with a double backslash (\\). |
| <b>szValue</b>  | Specifies the name of the value you want to delete.                                                                                                  |

## Return Values

**Table 30** ▪ RegDBDeleteValue Return Values

| Return Value  | Description                                                 |
|---------------|-------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully deleted the value. |
| <b>&lt; 0</b> | Indicates that the function was unable to delete the value. |

## Additional Information

- By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the `REGISTRYFUNCTIONS_USETEXTSUBS` argument.
- RegDBDeleteValue** does not write anything to the uninstall log file; thus, calling this function does not have any effect how the application is uninstalled.

## RegDBDeleteValue Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBDeleteValue function.
*
* RegDBDeleteValue is called to delete the value name "Cursive"
* from the following registry key:
*
```

```

* "HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Fonts".
*
* Note: Before running this script, set the preprocessor
*       constants so that they reference an existing subkey
*       and value on the target system.
*
\*-----*/

#define SUBKEY "\\Software\\Microsoft\\Windows\\CurrentVersion\\Fonts"
#define VALUE  "Cursive"
#define TITLE  "RegDBDeleteValue Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBDeleteValue(HWND);

function ExFn_RegDBDeleteValue(hMSI)
    STRING szSubKey, szValue, szTitle;
    NUMBER nReturn;
begin
    // Set the root key.
    RegDBSetDefaultRoot (HKEY_LOCAL_MACHINE);

    // Set the name of the subkey.
    szSubKey = SUBKEY;
    szValue  = VALUE;

    // Delete the subkey.
    nReturn = RegDBDeleteValue (szSubKey, szValue);

    // Report the results of the deletion.
    if (nReturn < 0) then
        MessageBox ("RegDBDeleteValue failed.", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE, "%s successfully deleted.", szValue);
    endif;

end;

```

## RegDBDisconnectRegistry

**Project** - For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBDisconnectRegistry** function closes a connection to a remote registry that you established by calling RegDBConnectRegistry.

After calling RegDBDisconnectRegistry, all calls to the InstallScript registry-related functions affect the local system's registry. For more information on special registry-related functions, see [Special Registry-Related Functions](#).

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

## Syntax

```
RegDBDisconnectRegistry ( nReserved );
```

## Parameters

**Table 31** ▪ RegDBDisconnectRegistry Parameters

| Parameter        | Description                                             |
|------------------|---------------------------------------------------------|
| <b>nReserved</b> | Pass zero in this parameter. No other value is allowed. |

## Return Values

**Table 32** ▪ RegDBDisconnectRegistry Return Values

| Return Value  | Description                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that this function successfully closed a connection to the registry on the remote system. |
| <b>&lt; 0</b> | Indicates that this function failed to close the registry connection.                               |

## RegDBDisconnectRegistry Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the RegDBConnectRegistry function and
 * RegDBDisconnectRegistry function.
 *
 * Note: In order for this script to run properly, you must set
 *       the preprocessor constants to a valid remote computer
 *       with remote administration enabled. Both computers
 *       must also have the remote-registry service enabled.
 *
 \*-----*/

#define REMOTE "IShield_NT1"

// Include Ifx.h for built-in InstallScript function prototypes.
```

```

#include "Ifx.h"

export prototype ExFn_RegDBDisConnectRegistry(HWND);

function ExFn_RegDBDisConnectRegistry(hMSI)
    STRING szRemoteMachine, szKey, szTitle, szMsg;
    NUMBER nKeyType, nReturn;
begin

    szTitle          = "RegDBConnectRegistry & RegDBDisConnectRegistry";
    szRemoteMachine = REMOTE;
    nKeyType          = HKEY_LOCAL_MACHINE;
    szMsg             = "Setup will now connect to %s.";

    sprintfBox (INFORMATION, szTitle, szMsg, szRemoteMachine);

    // Connect to the remote computer's registry. All registry-related
    // function calls will now alter only the remote computer.
    nReturn = RegDBConnectRegistry (szRemoteMachine, nKeyType, 0);

    if (nReturn < 0) then
        szMsg = "RegDBConnectRegistry failed.\n\nCould not connect to remote " +
            "system.";
        MessageBox (szMsg, SEVERE);
        abort;
    else
        szMsg = "Successfully connected to %s.";
        sprintfBox (INFORMATION, szTitle, szMsg, szRemoteMachine);
    endif;

    // Create a key on the remote computer.
    szKey  = "SOFTWARE\\InstallShield\\Test Key";
    nReturn = RegDBCreateKeyEx(szKey, "");

    if (nReturn < 0) then
        szMsg = "RegDBCreateKeyEx failed.\n\nCould not create key on remote " +
            "machine.";
        MessageBox (szMsg , SEVERE);
    else
        szMsg = "Successfully created %s on %s.";
        sprintfBox (INFORMATION, szTitle, szMsg, szKey, szRemoteMachine);

        // Verify that the key now exists in the remote registry.
        nReturn = RegDBKeyExist(szKey);

        if (nReturn < 0) then
            szMsg = "RegDBKeyExist failed.\n\nRemote key does not exist.";
            MessageBox (szMsg, SEVERE);
        else
            szMsg = "%s exists.";
            sprintfBox (INFORMATION, szTitle, szMsg, szKey);
        endif;
    endif;

    // Delete the key that was created on the remote computer.
    nReturn = RegDBDeleteKey(szKey);

```

```

if (nReturn < 0) then
    MessageBox("RegDBDeleteKey failed.\n\nRemote key could not be deleted.",
        INFORMATION);
else
    szMsg = "Successfully deleted %s on %s.";
    sprintfBox(INFORMATION, szTitle, szMsg, szKey, szRemoteMachine);
endif;

// Disconnect from the remote registry. All registry-related functions
// will now alter only the local registry.
nReturn = RegDBDisconnectRegistry(0);

if (nReturn < 0) then
    MessageBox("RegDBDisconnectRegistry failed.\n\nRemote registry still " +
        "connected.", SEVERE);
else
    MessageBox("RegDBDisconnectRegistry successful.\n\nRemote registry " +
        "disconnected.", INFORMATION);
endif;

end;

```

## RegDBGetAppInfo

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBGetAppInfo** function retrieves from the registry the value of a particular value name under the application information key of your main application. RegDBGetAppInfo is a special registry-related function, designed to work with certain predefined registry keys.

**Note** ▪ The InstallScript engine currently does not support writing or reading Add or Remove Programs information for a product in the 64-bit part of the registry. Therefore, using the REGDB\_OPTION\_WOW64\_64KEY option with the **REGDB\_OPTIONS** system variable is not supported for this registry function. Enabling the REGDB\_OPTION\_WOW64\_64KEY option has no effect on where registry entries are created by this function.

### Syntax

```
RegDBGetAppInfo ( szName, nvType, svValue, nvSize );
```

## Parameters

**Table 33** ▪ RegDBGetAppInfo Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szName</b>  | Specifies the value name of the value to retrieve.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>nvType</b>  | <p>Returns one of the following predefined constants, which identifies the type of data returned in svValue:</p> <ul style="list-style-type: none"> <li>• <b>REGDB_STRING</b>—String variable, no newline characters allowed.</li> <li>• <b>REGDB_STRING_EXPAND</b>—String variable holding an expandable environment variable expression, such as "%MYPATH%".</li> <li>• <b>REGDB_STRING_MULTI</b>—String variable, newline characters allowed.</li> <li>• <b>REGDB_NUMBER</b>—Number expressed as a string and passed in a string variable.</li> <li>• <b>REGDB_BINARY</b>—Binary data stored in a string.</li> </ul> |
| <b>svValue</b> | Returns the value of the value name specified in szName.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>nvSize</b>  | Returns the size—in bytes—of the return value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 34** ▪ RegDBGetAppInfo Return Values

| Return Value  | Description                                                   |
|---------------|---------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully retrieved the value. |
| <b>&lt; 0</b> | Indicates that the function was unable to retrieve the value. |

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the **REGISTRYFUNCTIONS\_USETEXTSUBS** argument.

## RegDBGetAppInfo Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
```

```

* InstallShield Example Script
*
* Demonstrates the RegDBSetAppInfo and RegDBGetAppInfo functions.
*
* Before calling either of these functions, you must call
* InstallationInfo to set the application information.
*
\*-----*/

```

## RegDBGetDefaultRoot

**Project** • For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBGetDefaultRoot** function returns the root key that is used by the general registry-related functions.

**Note** • This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

### Syntax

```
RegDBGetDefaultRoot ( );
```

### Parameters

None.

### Return Values

- HKEY\_CLASSES\_ROOT
- HKEY\_CURRENT\_USER
- HKEY\_LOCAL\_MACHINE
- HKEY\_USERS
- HKEY\_CURRENT\_CONFIG
- HKEY\_DYN\_DATA

- HKEY\_USER\_SELECTABLE

**Note** ▪ The return value `HKEY_USER_SELECTABLE` indicates that a subsequent registry function call uses `HKEY_LOCAL_MACHINE` as the root key if the `ALLUSERS` system variable is non-zero when the function is called, or uses `HKEY_CURRENT_USER` as the root key if `ALLUSERS` is `FALSE` when the function is called.

## RegDBGetItem

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBGetItem** function retrieves values under the per-application paths key or the application uninstallation key, depending on the value of `nItem`. **RegDBGetItem** is a special registry-related function, designed to work with certain predefined registry keys.

**Note** ▪ The InstallScript engine currently does not support writing or reading Add or Remove Programs information for a product in the 64-bit part of the registry. Therefore, using the `REGDB_OPTION_WOW64_64KEY` option with the `REGDB_OPTIONS` system variable is not supported for this registry function. Enabling the `REGDB_OPTION_WOW64_64KEY` option has no effect on where registry entries are created by this function.

### Syntax

```
RegDBGetItem ( nItem, svValue );
```

## Parameters

**Table 35** • RegDBGetItem Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

When this constant is used, szValue specifies the application name shown in the list of uninstallable applications in the Control Panel.</li> <li>● <b>REGDB_UNINSTALL_NOMODIFY</b>—The data of the NoModify value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_NOREMOVE</b>—The data of the NoRemove value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_NOREPAIR</b>—The data of the NoRepair value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_PRODUCTGUID</b>—The data of the ProductGuid value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_PRODUCTID</b>—The data of the ProductId value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_PUBLISHER</b>—The data of the Publisher value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_README</b>—The data of the Readme value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_REGCOMPANY</b>—The data of the RegCompany value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_REGOWNER</b>—The data of the RegOwner value under the uninstallation key.</li> </ul> |

**Table 35** • RegDBGetItem Parameters (cont.)

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nItem (cont.)</b> | <ul style="list-style-type: none"> <li>● <b>REGDB_UNINSTALL_STRING</b>—The data of the UninstallString value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_SYSTEMCOMPONENT</b>—The data of the SystemComponent value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_URLINFOABOUT</b>—The data of the URLInfoAbout value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_URLUPDATEINFO</b>—The data of the URLUpdateInfo value under the uninstallation key.</li> <li>● <b>REGDB_UNINSTALL_VERSION</b>—The data of the Version value under the uninstallation key. When this constant is used, svValue returns the installed product's version number expressed as a string, for example, "16777216".</li> <li>● <b>REGDB_WINCURRVER_REGORGANIZATION</b>—The data of the RegisteredOrganization value under the current version key.</li> <li>● <b>REGDB_WINCURRVER_REGOWNER</b>—The data of the RegisteredOwner value under the current version key.</li> </ul> |
| <b>svValue</b>       | Returns the value of the item.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Return Values

**Table 36** • RegDBGetItem Return Values

| Return Value  | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully retrieved the value of the item. |
| <b>&lt; 0</b> | Indicates that the function was unable to retrieve the value of the item. |

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the **REGISTRYFUNCTIONS\_USETEXTSUBS** argument.

**Project** • In an InstallScript installation, calling **RegDBSetItem** with **REGDB\_APPPATH** or **REGDB\_APPPATH\_DEFAULT** before calling **CreateInstallationInfo** has no net effect. This is because **CreateInstallationInfo** overwrites registry information that is created by **RegDBSetItem**, thus nullifying the call. Calling **RegDBSetItem** with any other constant before calling **MaintenanceStart** has no net effect. This is because **MaintenanceStart** overwrites the registry data created by **RegDBSetItem**, thus nullifying the call. (In an event-based script, **CreateInstallationInfo** and **MaintenanceStart** are called in the default **OnMoveData** event handler code.)

In an InstallScript MSI installation, the uninstallation information is created during file transfer by the Windows Installer. Therefore, if you call **RegDBSetItem** in an InstallScript MSI installation, you should call it only after file transfer.

## RegDBGetItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBSetItem and RegDBGetItem functions.
*
* This script sets several registry keys; then it gets those
* keys and displays their current values.
*
\*-----*/

    endif;

end;

```

# RegDBGetKeyValueEx

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBGetKeyValueEx** function retrieves the value of a particular value name under a specified key in the registry. By default, InstallShield assumes this key is a subkey of HKEY\_CLASSES\_ROOT. You can use **RegDBSetDefaultRoot** to specify another root key.

**RegDBGetKeyValueEx** is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions.

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

## Syntax

```
RegDBGetKeyValueEx ( szKey, szName, nvType, svValue, nvSize );
```

## Parameters

**Table 37** ▪ RegDBGetKeyValueEx Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>   | Specifies the name of the key whose value is to be retrieved. Separate different levels in the subkey with a double backslash (\\).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>szName</b>  | Specifies the value name under szKey of the value to retrieve. To retrieve the default value of the key, pass a null string ("").                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>nvType</b>  | <p>Returns one of the following predefined constants, which identifies the type of data returned in svValue:</p> <ul style="list-style-type: none"> <li>● <b>REGDB_STRING</b>—String variable, no newline characters allowed.</li> <li>● <b>REGDB_STRING_EXPAND</b>—String variable holding an expandable environment variable expression such as "%MYPATH%".</li> <li>● <b>REGDB_STRING_MULTI</b>—String variable, newline characters allowed.</li> <li>● <b>REGDB_NUMBER</b>—Number expressed as a string and passed in a string variable.</li> <li>● <b>REGDB_BINARY</b>—Binary data stored in a string.</li> </ul> <p></p> <p><b>Note</b> ▪ When data type <b>REGDB_STRING_MULTI</b> is retrieved, use <b>StrGetTokens</b> with null string ("" ) to parse the multiple null terminated strings into a list of strings. That is, if svValue has the resulting multiple strings after a call to <b>RegDBGetKeyValueEx</b>, <b>StrGetTokens( listID, svValue, "" )</b> can be used to parse the strings and put them in a string list (listID).</p> |
| <b>svValue</b> | Returns the value that was specified by szKey and svName. Note that a number value is returned as a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>nvSize</b>  | Returns the size—in bytes—of the value returned in svValue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Return Values

**Table 38** ▪ RegDBGetKeyValueEx Return Values

| Return Value  | Description                                                   |
|---------------|---------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully retrieved the value. |
| <b>&lt; 0</b> | Indicates that the function was unable to retrieve the value. |

## RegDBGetKeyValueEx Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the RegDBSetKeyValueEx and RegDBGetKeyValueEx
 * functions.
 *
 * RegDBCreateKeyEx is called to create a test subkey in the
 * HKEY_CLASSES_ROOT key. The value of a key is set in integer
 * form using the REGDB_NUMBER option of the RegDBSetKeyValueEx
 * function. After this value is set, it is retrieved using
 * the RegDBGetKeyValueEx function and verified.
 *
\*-----*/

#define TITLE "RegDBSetKeyValueEx & RegDBGetKeyValueEx"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBGetKeyValueEx(HWND);

function ExFn_RegDBGetKeyValueEx(hMSI)
    STRING szKey, szNumName, szNumValue, svNumValue, szTitle, szMsg;
    NUMBER nType, nSize, nvType, nvSize;
begin

    // Create a key to test.
    szKey = "TestKey";

    if (RegDBCreateKeyEx (szKey, "") < 0) then
        MessageBox ("RegDBCreateKeyEx failed.", SEVERE);
        abort;
    endif;

    // Set up parameters for call to RegDBSetKeyValueEx.
    szNumName = "TestValue";
    szNumValue = "12345";
    nType      = REGDB_NUMBER;
    nSize      = -1;

    // Set a key name and a value associated with it.
    if (RegDBSetKeyValueEx (szKey, szNumName, nType, szNumValue,
                           nSize) < 0) then
        MessageBox ("RegDBSetKeyValueEx failed.", SEVERE);
        abort;
    else
        // Display what RegDBSetKeyValueEx has done.
        szMsg = "%s set to: %s";
        sprintfBox (INFORMATION, TITLE, szMsg, szNumName, szNumValue);
    endif;
end;

```

```

// Retrieve key value information.
if (RegDBGetKeyValueEx (szKey, szNumName, nvType, svNumValue,
                        nvSize) < 0) then
    MessageBox ("RegDBGetKeyValueEx failed.", SEVERE);
else
    // Check to see if the value returned is the same as the value set.
    if (nvType != REGDB_NUMBER) then
        MessageBox ("Type comparison failed.", SEVERE);
    endif;

    if (svNumValue != szNumValue) then
        MessageBox ("Subkey value comparison failed.", SEVERE);
    endif;

    // Display what RegDBGetKeyValueEx retrieved.
    szMsg = "%s has value: %s\n\nThis data is %d bytes.";
    sprintfBox (INFORMATION, TITLE, szMsg, szNumName, svNumValue, nvSize);
endif;

// Delete the created test key.
if (RegDBDeleteKey (szKey) < 0) then
    MessageBox ("RegDBDeleteKey failed.", SEVERE);
endif;

end;

```

## RegDBGetUninstCmdLine

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBGetUninstCmdLine** function gets the registered command line for the uninstallation that is specified by szUninstallKey and returns the command line in svUninstCmdLine.

**Note** ▪ The InstallScript engine currently does not support writing or reading Add or Remove Programs information for a product in the 64-bit part of the registry. Therefore, using the REGDB\_OPTION\_WOW64\_64KEY option with the **REGDB\_OPTIONS** system variable is not supported for this registry function. Enabling the REGDB\_OPTION\_WOW64\_64KEY option has no effect on where registry entries are created by this function.

### Syntax

```
RegDBGetUninstCmdLine ( szUninstallKey, svUninstCmdLine );
```

## Parameters

**Table 39** • RegDBGetUninstCmdLine Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szUninstallKey</b>  | Specifies the name of a subkey under the target registry's <root key>\Software\Microsoft\Windows\CurrentVersion\Uninstall key; the function first checks for the subkey under the root key HKEY_CURRENT_USER, and if it does not find the subkey there, it checks under HKEY_LOCAL_MACHINE. For setups created with InstallShield Professional 5.53 or earlier, this is typically the name of the application; for setups created with InstallShield Professional 6.0 or later, this is the application's product GUID including the surrounding braces {}. |
| <b>svUninstCmdLine</b> | Returns the uninstallation command line that is specified in szUninstallKey's UninstallString value's data.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Return Values

**Table 40** • RegDBGetUninstCmdLine Return Values

| Return Value               | Description                                     |
|----------------------------|-------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully got the command line. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to get the command line.    |

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the REGISTRYFUNCTIONS\_USETEXTSUBS argument.

# RegDBKeyExist

**Project** • For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBKeyExist** function checks for the existence of a specific key in the registry. By default, InstallShield assumes this key is a subkey of HKEY\_CLASSES\_ROOT. If you want to use a different main key, use RegDBSetDefaultRoot to specify another root key.

RegDBKeyExist is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions. For more information on special registry-related functions, see [Special Registry-Related Functions](#).

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

### Syntax

```
RegDBKeyExist ( szSubKey );
```

### Parameters

**Table 41** ▪ RegDBKeyExist Parameters

| Parameter             | Description                                                                                                                                                                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>szSubKey</code> | Specifies the name of the key to find. You do not have to include the <code>HKEY_CLASSES_ROOT</code> key (or another root key you specified) in this parameter. Separate different levels in the subkey with a double backslash ( <code>\\</code> ). |

### Return Values

**Table 42** ▪ RegDBKeyExist Return Values

| Return Value        | Description                                                                  |
|---------------------|------------------------------------------------------------------------------|
| <code>1</code>      | Indicates that the function found the key name in the registry.              |
| <code>&lt; 0</code> | Indicates that the function was unable to find the key name in the registry. |

This function never returns zero (0).

### Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the `REGISTRYFUNCTIONS_USETEXTSUBS` argument.

## RegDBKeyExist Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBCreateKeyEx and RegDBKeyExist functions.
*
* First, RegDBCreateKeyEx is called to create a subkey with no
* class value in the HKEY_CLASSES_ROOT key. Then, RegDBKeyExist
* is then called to check if the key was created.
*
* RegDBCreateKeyEx is called again to create a multi-level subkey
* with a class value associated with it under HKEY_CLASSES_ROOT.
* Then RegDBKeyExist is called again to check for the existence
* of the new key.
*
\*-----*/

#define TITLE_TEXT "RegDBCreateKeyEx & RegDBKeyExist"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBKeyExist(HWND);

function ExFn_RegDBKeyExist(hMSI)
    STRING szKey, szClass, szKeyRoot, szMsg, svLogFile;

        MessageBox ("Second call to RegDBKeyExist failed.", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE_TEXT, "%s exists.", szKey);
    endif;
endif;

if (RegDBDeleteKey (szKey) < 0) then
    MessageBox ("RegDBDeleteKey failed.", SEVERE);
endif;

end;

```

## RegDBQueryKey

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBQueryKey** function allows users to query a key for its subkeys and value names. The keys can be enumerated dynamically at run time using this function. RegDBQueryKey is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions.

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

### Syntax

```
RegDBQueryKey ( szSubKey, nItem, listResults );
```

## Parameters

**Table 43** ▪ RegDBQueryKey Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSubKey</b>    | Specifies subkeys under one of the root keys that were set by a previous call to <a href="#">RegDBSetDefaultRoot</a> . Use backslashes to specify deeper levels of subkeys. To retrieve the root key, pass a null string ("").                                                                                                                                                                                            |
| <b>nItem</b>       | Specifies which items should be placed in the list. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>REGDB_KEYS</b>—The string list returned in listResults will contain a list of all the subkeys under this key.</li> <li>• <b>REGDB_NAMES</b>—The string list returned in listResults will contain the names of all named values for this key.</li> </ul> |
| <b>listResults</b> | Returns the results of the query in a string list. The list identified by listResults must already have been initialized by a call to <a href="#">ListCreate</a> .                                                                                                                                                                                                                                                        |

## Return Values

**Table 44** ▪ RegDBQueryKey Return Values

| Return Value  | Description                        |
|---------------|------------------------------------|
| <b>0</b>      | Indicates function was successful. |
| <b>&lt; 0</b> | Indicates function failed.         |

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the `REGISTRYFUNCTIONS_USETEXTSUBS` argument.

## RegDBQueryKey Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* Demonstrates the RegDBQueryKey function.
*
* First, RegDBQueryKey is called to query the subkeys under the
* key KEY1. The list returned by RegDBQueryKey is displayed
* in a dialog.
*
* Then RegDBQueryKey is called to query the subkeys under the
* key KEY2. This list is also displayed in a dialog.
*
\*-----*/

#define KEY1  "SOFTWARE"
#define KEY2  "SOFTWARE\\Microsoft"
#define TITLE "RegDBQueryKey Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBQueryKey(HWND);

function ExFn_RegDBQueryKey(hMSI)
    STRING szMsg;
    NUMBER nReturn, nItem;
    LIST   listSubKeys, listNames;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Create the lists to hold values returned by RegDBQueryKey.
    listSubKeys = ListCreate(STRINGLIST);
    listNames   = ListCreate(STRINGLIST);

    if ((listNames = LIST_NULL) || (listSubKeys = LIST_NULL)) then
        MessageBox ("Unable to create necessary lists.", SEVERE);
        abort;
    endif;

    RegDBSetDefaultRoot(HKEY_LOCAL_MACHINE);

    // Get the list of subkeys.
    nReturn = RegDBQueryKey(KEY1, REGDB_KEYS, listSubKeys );

    if (nReturn < 0) then
        MessageBox("First call to RegDBQueryKey failed.", SEVERE);
    else
        szMsg = "Subkeys under " + KEY1 + " key:";
        SdShowInfoList(TITLE, szMsg, listSubKeys );
    endif;

    // Get the list of subkeys.
    nReturn = RegDBQueryKey(KEY2, REGDB_NAMES, listNames);

    if (nReturn < 0) then
        MessageBox("Second call to RegDBQueryKey failed.", SEVERE);

```

```

else
    szMsg = "Named values under " + KEY2 + " key";
    SdShowInfoList(TITLE, szMsg, listNames);
endif;

// Remove the lists from memory.
ListDestroy (listNames);
ListDestroy (listSubKeys );

end;

```

## RegDBQueryKeyCount

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBQueryKeyCount** function returns the number of subkeys or values under szKey. nItem specifies whether subkeys or values are counted.

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

### Syntax

```
RegDBQueryKeyCount ( szKey, nItem );
```

## Parameters

**Table 45** ▪ RegDBQueryKeyCount Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b> | Specifies a key under the root key that was set by a previous call to <a href="#">RegDBSetDefaultRoot</a> . Use backslashes to specify deeper levels of subkeys. To specify the root key, pass a null string ("").                                                                  |
| <b>nItem</b> | Specifies which items should be counted. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>REGDB_KEYS</b>—The number of subkeys is returned.</li> <li>• <b>REGDB_NAMES</b>—The number of values is returned.</li> </ul> |

## Return Values

**Table 46** ▪ RegDBQueryKeyCount Return Values

| Return Value              | Description                                                                                                                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>X</b>                  | The number of items of the specified type under the specified key.                                                                                                                                                                               |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function could not determine the number of items.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

- **RegDBQueryKeyCount** is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions. For more information on special registry-related functions, see [Special Registry-Related Functions](#).
- By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the REGISTRYFUNCTIONS\_USETEXTSUBS argument.

# RegDBQueryStringMultiStringCount

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBQueryStringMultiStringCount** function returns the number of strings contained in the multistring value specified by `szValue` under the key specified by `szKey`.

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

## Syntax

```
RegDBQueryStringMultiStringCount ( szKey, szValue );
```

## Parameters

**Table 47** ▪ RegDBQueryStringMultiStringCount Parameters

| Parameter      | Description                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>   | Specifies a key under the root key that was set by a previous call to <a href="#">RegDBSetDefaultRoot</a> . Use backslashes to specify deeper levels of subkeys. To specify the root key, pass a null string (""). |
| <b>szValue</b> | Specifies the multistring value under <code>szKey</code> to check.                                                                                                                                                 |

## Return Values

**Table 48** ▪ RegDBQueryStringMultiStringCount Return Values

| Return Value              | Description                                                                                                                                                                                                                                           |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>X</b>                  | The number of substrings in the specified multistring value under the specified key.                                                                                                                                                                  |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function could not determine the number of substrings.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

- **RegDBQueryStringMultiStringCount** is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions. For more information on special registry-related functions, see [Special Registry-Related Functions](#).
- By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the `REGISTRYFUNCTIONS_USETEXTSUBS` argument.

# RegDBSetAppInfo

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBSetAppInfo** function sets the value of a particular value name under the application information key in the registry. RegDBSetAppInfo is a special registry-related function, designed to work with certain predefined registry keys.

**Note** ▪ The InstallScript engine currently does not support writing or reading Add or Remove Programs information for a product in the 64-bit part of the registry. Therefore, using the REGDB\_OPTION\_WOW64\_64KEY option with the **REGDB\_OPTIONS** system variable is not supported for this registry function. Enabling the REGDB\_OPTION\_WOW64\_64KEY option has no effect on where registry entries are created by this function.

## Syntax

```
RegDBSetAppInfo ( szName, nType, szValue, nSize );
```

## Parameters

**Table 49** ▪ RegDBSetAppInfo Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szName</b>  | Specifies the value name whose information is to be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>nType</b>   | <p>Specifies the type of data you are setting. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>REGDB_STRING</b>—String variable, no newline characters allowed.</li> <li>● <b>REGDB_STRING_EXPAND</b>—String variable holding an expandable environment variable expression, such as "%MYPATH%".</li> <li>● <b>REGDB_STRING_MULTI</b>—String variable, newline characters allowed.</li> <li>● <b>REGDB_NUMBER</b>—Number expressed as a string and passed in a string variable.</li> <li>● <b>REGDB_BINARY</b>—Binary data stored in a string.</li> </ul> |
| <b>szValue</b> | Specifies the value to set for the value name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>nSize</b>   | Specifies the size, in bytes, of the data passed to RegDBSetAppInfo. Pass -1 in this parameter to indicate that InstallShield should determine the size of the data.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Return Values

**Table 50** ▪ RegDBSetAppInfo Return Values

| Return Value  | Description                                                                    |
|---------------|--------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully assigned the value to the value name. |
| <b>&lt; 0</b> | Indicates that the function was unable to assign the value.                    |

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the **REGISTRYFUNCTIONS\_USETEXTSUBS** argument.

## RegDBSetAppInfo Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBSetAppInfo and RegDBGetAppInfo functions.
*
* Before calling either of these functions, you must call
* InstallationInfo to set the application information.
*

## RegDBSetDefaultRoot

**Project** - For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBSetDefaultRoot** function sets the root key that is used by the general registry-related functions. Most InstallScript registry functions work on the HKEY\_CLASSES\_ROOT as the default registry hive. Using this function, you can specify another key, such as HKEY\_LOCAL\_MACHINE, HKEY\_CURRENT\_USER, or HKEY\_USERS, as the root key.

You cannot use **RegDBSetDefaultRoot** to change the root key of keys created or handled using the special registry-related functions. For more information, see [Special Registry-Related Functions](#).

**Note** - This function supports the 64-bit parts of the registry by using the REGDB\_OPTION\_WOW64\_64KEY option. For more information, see [REGDB\\_OPTIONS](#).

### Syntax

```
RegDBSetDefaultRoot ( nRootKey );
```

## Parameters

**Table 51** ▪ RegDBSetDefaultRoot Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nRootKey</b> | <p>Specify one of the following constants for the root key:</p> <ul style="list-style-type: none"> <li>• HKEY_CLASSES_ROOT</li> <li>• HKEY_CURRENT_USER</li> <li>• HKEY_LOCAL_MACHINE</li> <li>• HKEY_USERS</li> <li>• HKEY_CURRENT_CONFIG</li> <li>• HKEY_DYN_DATA</li> <li>• HKEY_USER_SELECTABLE</li> </ul> <p>If you pass HKEY_USER_SELECTABLE as the argument, a subsequent registry function call uses HKEY_LOCAL_MACHINE as the root key if the <a href="#">ALLUSERS</a> system variable is non-zero when the function is called, or uses HKEY_CURRENT_USER as the root key if ALLUSERS is FALSE when the function is called.</p> <div>  <p><b>Note</b> ▪ Windows does not allow the creation of a key directly under HKEY_LOCAL_MACHINE or HKEY_USERS.</p> </div> |

## Return Values

**Table 52** ▪ RegDBSetDefaultRoot Return Values

| Return Value  | Description                                            |
|---------------|--------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully set the key.  |
| <b>&lt; 0</b> | Indicates that the function was unable to set the key. |

## RegDBSetDefaultRoot Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBSetDefaultRoot function.
*
```

```

* RegDBSetDefaultRoot is called to set the default root key for
* the RegDBCreateKeyEx function.
*
* Note: Windows does not allow the creation of a key
*       directly under HKEY_LOCAL_MACHINE or HKEY_USERS.
*
\*-----*/

#define TITLE "RegDBSetDefaultRoot Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBSetDefaultRoot(HWND);

function ExFn_RegDBSetDefaultRoot(hMSI)
    STRING szKey, szClass, szMsg, szTitle;
    NUMBER nRootKey;
begin

    // Create a subkey in the HKEY_CLASSES_ROOT key (default).
    szKey   = "Test Key";
    szClass = "";

    if (RegDBCreateKeyEx (szKey, szClass) < 0) then
        MessageBox ("RegDBCreateKeyEx failed.", SEVERE);
        abort;
    else
        szMsg = "Successfully created %s in HKEY_CLASSES_ROOT.";
        sprintfBox (INFORMATION, TITLE, szMsg, szKey);
    endif;

    // Set the root key to HKEY_LOCAL_MACHINE.
    nRootKey = HKEY_LOCAL_MACHINE;

    if (RegDBSetDefaultRoot (nRootKey) < 0) then
        MessageBox ("First call to RegDBSetDefaultRoot failed.", SEVERE);
    else
        MessageBox ("Root key successfully set to HKEY_LOCAL_MACHINE.",
                    INFORMATION);
    endif;

    // Create a subkey in the HKEY_LOCAL_MACHINE key.
    if (RegDBCreateKeyEx (szKey, szClass) < 0) then
        MessageBox ("RegDBCreateKeyEx failed.", SEVERE);
        abort;
    else
        szMsg = "Successfully created %s in HKEY_LOCAL_MACHINE";
        sprintfBox (INFORMATION, TITLE, szMsg, szKey);
    endif;

    // Delete the example subkey in HKEY_LOCAL_MACHINE.
    if (RegDBDeleteKey (szKey) < 0) then
        MessageBox ("RegDBDeleteKey failed.", SEVERE);
    else
        szMsg = "Successfully deleted %s in HKEY_LOCAL_MACHINE";

```

```

        sprintfBox (INFORMATION, TITLE, szMsg, szKey);
    endif;

    // Set the root key to HKEY_CLASSES_ROOT again.
    nRootKey = HKEY_CLASSES_ROOT;

    if (RegDBSetDefaultRoot (nRootKey) < 0) then
        MessageBox ("Second call to RegDBSetDefaultRoot failed.", SEVERE);
    else
        MessageBox ("Root key successfully set to HKEY_CLASSES_ROOT.",
                    INFORMATION);
    endif;

    if (RegDBDeleteKey (szKey) < 0) then
        MessageBox ("RegDBDeleteKey failed.", SEVERE);
    else
        szMsg = "Successfully deleted %s in HKEY_CLASSES_ROOT";
        sprintfBox (INFORMATION, TITLE, szMsg, szKey);
    endif;

end;

```

## RegDBSetItem

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

**RegDBSetItem** is a special registry-related function, designed to work with certain predefined registry keys. The **RegDBSetItem** function assigns values under the per application paths key or the application uninstallation key, depending on the value of `nItem`. Calling **RegDBSetItem** with either the `REGDB_APPPATH` or the `REGDB_APPPATH_DEFAULT` option results in the creation of the per application paths key.

**Note** ▪ The InstallScript engine currently does not support writing or reading Add or Remove Programs information for a product in the 64-bit part of the registry. Therefore, using the `REGDB_OPTION_WOW64_64KEY` option with the `REGDB_OPTIONS` system variable is not supported for this registry function. Enabling the `REGDB_OPTION_WOW64_64KEY` option has no effect on where registry entries are created by this function.

### Syntax

```
RegDBSetItem ( nItem, szValue );
```

## Parameters

**Table 53** • RegDBSetItem Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nItem</b> | <p>Specifies the item to set. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>REGDB_APPPATH</b>—The data of the Path value under the per-application paths key. This key is created by the installation as a result of calling <b>CreateInstallationInfo</b>. You must call <b>CreateInstallationInfo</b> to create this key before calling <b>RegDBSetItem</b>. (In an event-based script, <b>CreateInstallationInfo</b> is called in the default <b>OnMoveData</b> event handler code.)</li> <li>• <b>REGDB_APPPATH_DEFAULT</b>—The data of the DefaultPath value under the per-application paths key. This key is created by the installation as a result of calling <b>CreateInstallationInfo</b>. You must call <b>CreateInstallationInfo</b> to create this key before calling <b>RegDBSetItem</b>. (In an event-based script, <b>CreateInstallationInfo</b> is called in the default <b>OnMoveData</b> event handler code.)</li> <li>• <b>REGDB_UNINSTALL_COMMENTS</b>—The data of the Comments value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_CONTACT</b>—The data of the Contact value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_DISPLAY_VERSION</b>—The data of the DisplayVersion value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_DISPLAYICON</b>—The data of the DisplayIcon value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_HELPLINK</b>—The data of the HelpLink value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_HELPTELEPHONE</b>—The data of the HelpTelephone value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_INSTALLDATE</b>—The data of the InstallDate value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_INSTALLLOC</b>—The data of the InstallLocation value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_INSTALLSOURCE</b>—The data of the InstallSource value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_LANGUAGE</b>—The data of the Language value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_LOGFILE</b>—The data of the LogFile value under the uninstallation key.</li> <li>• <b>REGDB_UNINSTALL_MAINT_OPTION</b>—The data of the LogMode value under the uninstallation key.</li> </ul> |

|                         |  <p><b>Important</b> ▪ Do not use <b>REGDB_WINCURREVER_REGOWNER</b> or <b>REGDB_WINCURREVER_REGORGANIZATION</b> with this function. Windows sets these values, and they should not be set by an installation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>szValue</b>          | Specifies the value to assign to the specified item.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 54** ▪ RegDBSetItem Return Values

| Return Value  | Description                                             |
|---------------|---------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully set the value. |
| <b>&lt; 0</b> | Indicates that the function failed.                     |

## Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the **REGISTRYFUNCTIONS\_USETEXTSUBS** argument.

## RegDBSetItem Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBSetItem and RegDBGetItem functions.
*
* This script sets several registry keys; then it gets those
* keys and displays their current values.
*
\*-----*/

endif;

end;

```

## RegDBSetKeyValueEx

**Project** - For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBSetKeyValueEx** function sets the value of a particular value name under a specified key in the registry.

If the value name does not already exist, **RegDBSetKeyValueEx** creates it. If the value data already exists, **RegDBSetKeyValueEx** overwrites it.

If the key does not already exist, **RegDBSetKeyValueEx** calls [RegDBCreateKeyEx](#), passing the key from the `szKey` parameter to create it.

**RegDBSetKeyValueEx** is a general registry-related function, designed to work with all registry keys, including those handled by the special registry-related functions.

---

**Note** ▪ This function supports the 64-bit parts of the registry by using the `REGDB_OPTION_WOW64_64KEY` option. For more information, see [REGDB\\_OPTIONS](#).

## Syntax

```
RegDBSetKeyValueEx ( szKey, szName, nType, szValue, nSize );
```

## Parameters

**Table 55** • RegDBSetKeyValueEx Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szKey</b>   | <p>Specifies the name of the key. Separate different levels in the subkey with a double backslash (\\).</p> <p>If the root key is HKEY_CLASSES_ROOT, you do not need to specify the HKEY_CLASSES_ROOT in this parameter. Unless you specify otherwise, the InstallScript engine assumes that the value that is being set is under the key HKEY_CLASSES_ROOT. To specify a different root key, you can call <a href="#">RegDBSetDefaultRoot</a> before calling <b>RegDBSetKeyValueEx</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>szName</b>  | Specifies the value name for the value data to set be set. To set the default value of the key specified in szKey, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>nType</b>   | <p>Specifies the type of data to be set. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>REGDB_STRING</b>—A string variable; no newline characters allowed.</li> <li>● <b>REGDB_STRING_EXPAND</b>—A string variable holding an expandable environment variable expression, such as "%MYPATH%".</li> <li>● <b>REGDB_STRING_MULTI</b>—A string variable; newline characters allowed.</li> <li>● <b>REGDB_NUMBER</b>—A number expressed as a string and passed in string variable. Creates data of type DWORD. When nType is REGDB_NUMBER, passing a decimal string in szValue results in a numeric value being stored in the registry. This numeric value is then displayed as a hexadecimal number followed by its decimal equivalent in parentheses. You cannot pass a hexadecimal number in the string in szValue—it <i>must</i> be a decimal number.</li> <li>● <b>REGDB_BINARY</b>—Binary data stored in a string.</li> </ul> |
| <b>szValue</b> | Specifies the value to associate with the value name. All values must be passed as string variables. Numbers must be expressed as strings. The InstallScript engine converts them to numbers internally.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>nSize</b>   | Specifies the size—in bytes—of the data to be set. You can specify -1 in this parameter when nType is REGDB_STRING, REGDB_STRING_EXPAND, or REGDB_NUMBER, and the InstallScript engine will set the size. However, with REGDB_BINARY and REGDB_STRING_MULTI, you must always specify the number of bytes of binary data that you are storing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Return Values

Table 56 ▪ RegDBSetKeyValueEx Return Values

| Return Value | Description                                            |
|--------------|--------------------------------------------------------|
| 0            | Indicates that the function successfully set the key.  |
| < 0          | Indicates that the function was unable to set the key. |

Additional Information

By default, any text that is surrounded by angle brackets—for example, "<my registry entry text>"—in this function's string arguments is interpreted as a text substitution and is processed accordingly. To disable text substitution processing for the string arguments of registry functions, call **Disable** with the REGISTRYFUNCTIONS\_USETEXTSUBS argument.

RegDBSetKeyValueEx Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegDBSetKeyValueEx and RegDBGetKeyValueEx
* functions.
*
* RegDBCreateKeyEx is called to create a test subkey in the
* HKEY_CLASSES_ROOT key. The value of a key is set in integer
* form using the REGDB_NUMBER option of the RegDBSetKeyValueEx
* function. After this value is set, it is retrieved using
* the RegDBGetKeyValueEx function and verified.
*
\*-----*/

#define TITLE "RegDBSetKeyValueEx & RegDBGetKeyValueEx"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RegDBSetKeyValueEx(HWND);

function ExFn_RegDBSetKeyValueEx(hMSI)
    STRING szKey, szNumName, szNumValue, svNumValue, szTitle, szMsg;
    NUMBER nType, nSize, nvType, nvSize;
begin

    // Create a key to test.
    szKey = "TestKey";
```

```

if (RegDBCreateKeyEx (szKey, "") < 0) then
    MessageBox ("RegDBCreateKeyEx failed.", SEVERE);
    abort;
endif;

// Set up parameters for call to RegDBSetKeyValueEx.
szNumName = "TestValue";
szNumValue = "12345";
nType      = REGDB_NUMBER;
nSize      = -1;

// Set a key name and a value associated with it.
if (RegDBSetKeyValueEx (szKey, szNumName, nType, szNumValue,
                        nSize) < 0) then
    MessageBox ("RegDBSetKeyValueEx failed.", SEVERE);
    abort;
else
    // Display what RegDBSetKeyValueEx has done.
    szMsg = "%s set to: %s";
    sprintfBox (INFORMATION, TITLE, szMsg, szNumName, szNumValue);
endif;

// Retrieve key value information.
if (RegDBGetKeyValueEx (szKey, szNumName, nvType, svNumValue,
                        nvSize) < 0) then
    MessageBox ("RegDBGetKeyValueEx failed.", SEVERE);
else
    // Check to see if the value returned is the same as the value set.
    if (nvType != REGDB_NUMBER) then
        MessageBox ("Type comparison failed.", SEVERE);
    endif;

    if (svNumValue != szNumValue) then
        MessageBox ("Subkey value comparison failed.", SEVERE);
    endif;

    // Display what RegDBGetKeyValueEx retrieved.
    szMsg = "%s has value: %s\n\nThis data is %d bytes.";
    sprintfBox (INFORMATION, TITLE, szMsg, szNumName, svNumValue, nvSize);
endif;

// Delete the created test key.
if (RegDBDeleteKey (szKey) < 0) then
    MessageBox ("RegDBDeleteKey failed.", SEVERE);
endif;

end;

```

# RegDBSetVersion

**Project** ▪ For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.

The **RegDBSetVersion** function places the value of the system variable **IFX\_PRODUCT\_VERSION** as the data for the Version value under the application uninstallation registry key, creating the registry value if it does not already exist. If IFX\_PRODUCT\_VERSION is not in packed DWORD format, the function fails.

**Note** ▪ This function supports the 64-bit parts of the registry by using the **REGDB\_OPTION\_WOW64\_64KEY** option. For more information, see **REGDB\_OPTIONS**.

## Syntax

```
RegDBSetVersion ( );
```

## Parameters

None.

## Return Values

**Table 57** ▪ RegDBSetVersion Return Values

| Return Value               | Description                                                      |
|----------------------------|------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully placed the data in the registry value. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to place data in the registry.               |

## Additional Information

RegDBSetVersion is called by the default code for the OnMoveData event handler function.

# RegisterFontResource

The **RegisterFontResource** function registers or unregisters the font resource specified by szFileName. This function is called by the default code for the **OnInstalledFontFile** and **OnUninstallingFontFile** event handler functions.

## Syntax

```
RegisterFontResource ( szFileName, svFontTitle, bRegister, nOptions );
```

## Parameters

**Table 58** • RegisterFontResource Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>  | Specifies the fully qualified file name of the font file (.fnt, .fon, .fot, .mmm, .otf, .pfb, .pfm, .ttc, or .ttf file) to be registered or unregistered. Typically you would install a font file to FOLDER_FONTS. Only a font file that exists on the target system can be registered, and you must unregister a font file before you remove it from the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>svFontTitle</b> | <p>This parameter must be a variable name and not a literal value. When RegisterFontResource is called, this parameter specifies the title for the font, if its value is not a null string (""); when RegisterFontResource returns, this parameter contains the title that was used when registering or unregistering the font file.</p> <p>If the font file being registered or unregistered is a TrueType font file, you can specify in this parameter a string variable whose value is a null string. In this case RegisterFontResource attempts to get the title by internally calling <a href="#">GetTrueTypeFontFileInfo</a>; if this fails, the file name of the font file is used as the title.</p> <p>If the REGFONT_OPTION_DONTUPDATeregistry option is specified in this function's fourth argument, svFontTitle is ignored.</p> |
| <b>bRegister</b>   | Specifies whether to register the font resource (TRUE) or unregister the font resource (FALSE).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 58** ▪ RegisterFontResource Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOptions</b> | <p>Specifies various options. Pass one of the following constants in this parameter, or combine these constants using the OR operator ( ):</p> <ul style="list-style-type: none"> <li>● <b>REGFONT_OPTION_DEFAULT</b>—Specifies that the function has its default behavior.</li> <li>● <b>REGFONT_OPTION_DONTBROADCASTFONTCHANGEMSG</b>—Specifies that the function does not send a message to top level windows indicating that font information has changed after registering or registering the font. You should specify this flag only if your installation sends this message manually after calling this function by calling the Windows API function <code>PostMessage</code> as in the following example: <pre>PostMessage( HWND_BROADCAST, WM_FONTCHANGE, 0, 0 );</pre> <p>You would typically use this flag if you are calling <code>RegisterFontResource</code> multiple times to update multiple fonts and then calling <code>PostMessage</code>.</p> </li> <li>● <b>REGFONT_OPTION_DONTUPDATEREGISTRY</b>—Specifies that the function does not add the font registration information to the registry or remove the font information from the registry. If you specify this option for font registration, the font is available only until the next time the system is rebooted. Note that if this option is specified <code>svFontTitle</code> is ignored.</li> </ul> |

## Return Values

**Table 59** ▪ RegisterFontResource Return Values

| Return Value               | Description                                                                   |
|----------------------------|-------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully registered or unregistered the font. |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to register or unregister the font.    |

## Additional Information

- Font information is written to `HKEY_LOCAL_MACHINE` in all cases, so typically in order to install a font the end user must have administrator privileges on the system.

- The function calls `PostMessage` instead of `SendMessage` to send the `WM_FONTCHANGE` message. This is because `SendMessage` (when used with `HWND_BROADCAST`) waits for all open windows to respond to the message before returning, which could cause the installation to freeze if an open window on the system fails to respond to the message. Since the function calls `PostMessage`, the function could return before Windows has processed the message and released the font from the font cache; so when using this function to uninstall fonts, it is recommended that you wait a few seconds (by calling [Delay](#)) before removing the font file.
- If you call this function in a feature event or a file install event (such as `OnInstallingFile` or `OnInstalledFile`) the font registration is associated with the corresponding feature and the font is automatically unregistered before the file or feature is uninstalled.

## RegisterFontResource Example

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RegisterFontResource function.
*
\*-----*/

function OnBegin()
    string szFileName, svFontTitle;
begin
    szFileName = FOLDER_FONTS ^ "Estre.ttf";
    svFontTitle = "Estrangelo Edessa";
    RegisterFontResource ( szFileName, svFontTitle, TRUE, REGFONT_OPTION_DEFAULT );
    // If you cut and paste this sample script into a project
    // and run it, the following line aborts execution of the script.
    abort;
end;
```

## ReleaseDialog

The **ReleaseDialog** function frees all memory associated with the custom dialog identified in `szDialogName`. Call this function after calling [EndDialog](#). Call this function outside the message-handling case statement.

### Syntax

```
ReleaseDialog ( szDialogName );
```

## Parameters

**Table 60** ▪ ReleaseDialog Parameters

| Parameter           | Description                                  |
|---------------------|----------------------------------------------|
| <b>szDialogName</b> | Specifies the name of the dialog to destroy. |

## Return Values

**Table 61** ▪ ReleaseDialog Return Values

| Return Value               | Description                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------|
| <b>0</b>                   | Indicates that the function successfully freed all memory associated with the custom dialog.   |
| <b>DLG_ERR (-1)</b>        | Function failed. The dialog name may be invalid.                                               |
| <b>DLG_ERR_ENDDLG (-2)</b> | ReleaseDialog was called before EndDialog. You must call EndDialog first to remove the dialog. |

## ReleaseDialog Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DefineDialog, EndDialog, and ReleaseDialog
* functions.
*
* This script opens a simple custom dialog that displays
* a bitmap. The dialog can be closed with any of three
* buttons: Back, Next, or Cancel.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdBitmap. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
* In order to use this dialog as a custom dialog, the
* script first defines it by calling DefineDialog. It then
* displays the dialog by calling WaitOnDialog. When an event
```

```

* ends dialog processing, EndDialog is called to close the
* dialog. Then the dialog is released from memory by
* a call to ReleaseDialog.
*
\*-----*/

// Dialog and control IDs.
#define RES_DIALOG_ID      12027  // ID of dialog itself
#define RES_PBUT_NEXT      1      // ID of Next button
#define RES_PBUT_CANCEL    9      // ID of Cancel button
#define RES_PBUT_BACK      12     // ID of Back button

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ReleaseDialog(HWND);

function ExFn_ReleaseDialog(hMSI)
    STRING  szDialogName, szDLLName, szDialog;

        bDone = TRUE;
        abort;
    endif;
end;

```

```

// Initialize the indicator used to control the while loop.
bDone = FALSE;

// Loop until done.
repeat

    // Display the dialog and return the next dialog event.
    nCmdValue = WaitOnDialog(szDialogName);

    // Respond to the event.
    switch (nCmdValue)
    case DLG_CLOSE:
        // The user clicked the window's Close button.
        Do (EXIT);
    case DLG_ERR:
        MessageBox ("Unable to display dialog. Setup canceled.", SEVERE);
        abort;
    case DLG_INIT:
        // Initialize the back, next, and cancel button enable/disable states
        // for this dialog and replace %P, %VS, %VI with
        // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
        // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
        hwndDlg = CmdGetHwndDlg(szDialogName);
        SdGeneralInit(szDialogName, hwndDlg, 0, "");
    case RES_PBUT_CANCEL:
        // The user clicked the Cancel button.
        Do (EXIT);
    case RES_PBUT_NEXT:
        bDone = TRUE;
    case RES_PBUT_BACK:
        bDone = TRUE;
    endswitch;

until bDone;

// Close the dialog.
EndDialog (szDialogName);

// Free the dialog from memory.
ReleaseDialog (szDialogName);

end;

```

## RenameFile

The **RenameFile** function changes the name of a file or directory and/or moves a file or directory (and its subdirectories and files) from one parent directory to another.

**Note** ■ Note the following:

- If *szSource* and *szTarget* reference the same directory or—when using unqualified names, if *SRCDIR* and *TARGETDIR* reference the same directory for an InstallScript installation (or if *SRCDIR* and *INSTALLDIR* reference the same directory for a Basic MSI or InstallScript MSI installation)—the file or directory that is

*specified by szSource is renamed, unless a file or directory with the name that is specified by szTarget already exists in that directory.*

- *If szSource and szTarget reference different directories or—when using unqualified names, if SRCDIR and TARGETDIR reference different directories for an InstallScript installation (or if SRCDIR and INSTALLDIR reference different directory for a Basic MSI or InstallScript MSI installation)—the file or directory that is specified by szSource is moved to the new directory and given the name that is specified by szTarget, unless a file or directory with that name already exists in that directory.*

## Syntax

```
RenameFile ( szSource, szTarget );
```

## Parameters

**Table 62** ▪ RenameFile Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSource</b> | <p>Specifies the name of the file or directory to be renamed or moved. If szFileOld specifies a fully qualified file name or directory (it includes a path), <b>RenameFile</b> renames or moves the file or directory in the specified directory. If szSource contains an unqualified file name or directory name (without path information), <b>RenameFile</b> renames or moves the file or directory in the directory specified by the system variable <b>SRCDIR</b>.</p> <p></p> <p><b>Note</b> ▪ Wildcard characters are not permitted. Only one file or one directory (including its subdirectories and folders) can be renamed or moved with each call to <b>RenameFile</b>.</p> |
| <b>szTarget</b> | <p>Specifies a new name and/or location for the file or directory. If szFileNew specifies a fully qualified file name or directory (it includes a path), <b>RenameFile</b> renames the file or moves it to the specified directory. If szFileNew contains an unqualified file name or directory name (without path information), <b>RenameFile</b> either renames the file or directory, or moves the file or directory to the directory specified by the system variable <b>TARGETDIR</b> (for an InstallScript installation) or the system variable <b>INSTALLDIR</b> (for a Basic MSI or InstallScript MSI installation).</p>                                                                                                                                        |

## Return Values

**Table 63** ▪ RenameFile Return Values

| Return Value  | Description                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully changed the name of the file or directory or moved the file or directory. |
| <b>&lt; 0</b> | Indicates that the function was unable to change the name of the file or folder or move the file or folder.        |

## RenameFile Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* Demonstrates the RenameFile function.
*
* First, RenameFile is called to rename FILENAME1 to FILENAME2.
* It is then called again to move the FILENAME2 file to the
* TARGET directory.
*
* This can also be done in one call to RenameFile. The third
* call to RenameFile demonstrates this by renaming and moving
* the FILENAME2 file from the TARGET directory to the SOURCE
* directory, with the FILENAME1 file name.
*
* Note: Before running this script, set the preprocessor
*       constants so that they specify valid file names and
*       paths on the target system.
*
\*-----*/

#define FILENAME1 "ISExempl.txt"
#define FILENAME2 "ISExempl.bak"
#define SOURCE_DIR "C:\\ISExempl\\Source"
#define TARGET_DIR "C:\\ISExempl\\Target"
#define TITLE      "RenameFile Example"

#include "ifx.h"

function OnBegin()
begin

    // Set up system variables for rename operation.
    SRCDIR    = SOURCE_DIR;
    TARGETDIR = SOURCE_DIR;

    // Rename FILENAME1 to FILENAME2.
    if (RenameFile (FILENAME1, FILENAME2) < 0) then
        MessageBox("First call to RenameFile failed.", SEVERE);
        abort;
    else
        szMsg = "%s successfully renamed to %s.";
        sprintfBox(INFORMATION, szTitle, szMsg, FILENAME1, FILENAME2);
    endif;

    // Set up system variables to move a file from one directory to another.
    SRCDIR    = SOURCE_DIR;
    TARGETDIR = TARGET_DIR;

    // Move the file from the SOURCE to the TARGET directory.
    if (RenameFile(FILENAME2, FILENAME2) < 0) then
        MessageBox("Second call to RenameFile failed.", SEVERE);
        abort;
    else
        szMsg = "%s successfully moved to %s.";
        sprintfBox(INFORMATION, TITLE, szMsg, FILENAME2, TARGETDIR);
    endif;

```

```

// Set up system variables to move the file back to its original location.
SRCDIR    = TARGET_DIR;
TARGETDIR = SOURCE_DIR;

// Rename the file and move it from the TARGET directory
// to the SOURCE directory.
if (RenameFile(FILENAME2, FILENAME1) < 0) then
    MessageBox("Third call to RenameFile failed.", SEVERE);
    abort;
else
    szMsg = "%s successfully renamed %s and moved to the directory %s.";
    sprintfBox(INFORMATION, TITLE, szMsg, FILENAME2, FILENAME1, TARGETDIR);
endif;

end;

```

## ReplaceFolderIcon

The [ReplaceShortcut](#) function supersedes the **ReplaceFolderIcon** function.

The **ReplaceFolderIcon** function replaces a shortcut in a specified folder. You must specify an existing folder, either one you have created with the [CreateProgramFolder](#) function or one that already exists on the user's system.

### Syntax

```

ReplaceFolderIcon ( szProgramFolder, szItemName, szNewItem, szCmdLine, szWorkingDir, szIconPath, nIcon,
    szShortCutKey, nFlag );

```

## Parameters

**Table 64** ▪ ReplaceFolderIcon Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szProgramFolder</b> | Specify the name of the folder that contains the shortcut to replace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szItemName</b>      | Specify the name of the shortcut to replace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>szNewItem</b>       | Specify the name of the shortcut as it should appear after the replacement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>szCmdLine</b>       | Specify one of the following: <ul style="list-style-type: none"> <li>• The fully qualified name of the executable associated with the icon, including any command-line parameters.</li> <li>• The fully qualified path if szItemName is a subfolder.</li> </ul>                                                                                                                                                                                                                                                                                         |
| <b>szWorkingDir</b>    | Specify the directory where the application's program files are located. (Not applicable if szItemName is a subfolder.) To make the directory that contains the program file the working directory, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                          |
| <b>szIconPath</b>      | Specify the name of an icon file or a valid Windows executable that contains the new icon.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>nIcon</b>           | If you specified an executable file for szIconPath, specify the icon index in the executable file. Otherwise, enter the number 0 for nIcon.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>szShortCutKey</b>   | Specify the string that contains the shortcut key sequence the user can press to start the program. For example, if you wanted the user to be able to open the application by depressing the "Ctrl," the "Alt," and then the "1" key, specify "Ctrl + Alt + 1" in this parameter.                                                                                                                                                                                                                                                                       |
| <b>nFlag</b>           | Specify one or more options. Pass the following predefined constants in this parameter. To specify more than one option, combine constants with the OR ( ) operator. <ul style="list-style-type: none"> <li>• <b>NULL</b>—Indicates no options.</li> <li>• <b>REPLACE</b>—Indicates that the existing icon should be replaced with the new icon.</li> <li>• <b>RUN_MAXIMIZED</b>—Indicates that the program should be maximized when launched.</li> <li>• <b>RUN_MINIMIZED</b>—Indicates that the program should be minimized when launched.</li> </ul> |

## Return Values

**Table 65** ▪ ReplaceFolderIcon Return Values

| Return Value | Description                                                                                                                                                                                                                             |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully replaced the shortcut.                                                                                                                                                                         |
| < 0          | Indicates that the function was unable to replace the icon.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## ReplaceFolderIcon Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ReplaceFolderIcon function.
*
* Note: In order for this script to run correctly, you must set
*       preprocessor constants to valid file names and a path
*       on the target system. To easily create this example
*       folder and icon, run the AddFolderIcon example #3.
*
\*-----*/

#define FOLDER      "C:\\Windows\\"
#define NEW_PROGRAM "C:\\WINDOWS\\WRITE.EXE"
#define NEW_PARAM   "C:\\WINDOWS\\README.TXT"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ReplaceFolderIcon(HWND);

function ExFn_ReplaceFolderIcon(hMSI)
    STRING szProgramFolder, szItemName, szNewItem, szCmdLine, szWorkingDir;
    STRING szShortCutKey, szIconPath, szProgram, szParam;
    NUMBER nIcon, nFlag;
begin

    szProgramFolder = FOLDER ^ "Example folder";
    szItemName      = "Notepad Example";
    szNewItem       = "New Wordpad Example";

    // Make sure the space is not seen as a delimiter.
    szProgram = NEW_PROGRAM;

```

```

LongPathToQuote (szProgram, TRUE);

szParam = NEW_PARAM;
LongPathToShortPath(szParam);

szCmdLine      = szProgram + " " + szParam;
szWorkingDir   = "";
szIconPath     = "";
nIcon          = 0;
szShortCutKey  = "";
nFlag          = REPLACE|RUN_MAXIMIZED;

// Display the folder on the screen.
ShowProgramFolder (szProgramFolder, SW_SHOW);

// Replace the "Notepad Example" icon with "New Wordpad Example".
if (ReplaceFolderIcon (szProgramFolder, szItemName, szNewItem, szCmdLine,
                      szWorkingDir, szIconPath, nIcon, szShortCutKey,
                      nFlag) < 0) then
    MessageBox ("ReplaceFolderIcon failed.", SEVERE);
else
    MessageBox ("Icon successfully replaced.", INFORMATION);
endif;

end;

```

## ReplaceProfString

In Windows Installer based projects, all .ini file changes should be created in the INI Files view of the IDE. Handling all of your .ini file changes in this way allows for a clean uninstallation through the Windows Installer service.

The **ReplaceProfString** function replaces a profile string in an .ini file. This function can replace values of duplicate keys (non-unique keys) such as those found in the [386Enh] section of the System.ini file (device = ...). The function searches for a szKeyName = szOrigValue, and replaces the line. If it is not found, it adds the szKeyName = szReplaceValue line to the beginning of the szSectionName section.

If you are adding unique keys (that is, keys that are all different for a given section), use the [WriteProfString](#) function.

Use this function to replace only non-unique key names, such as the device= line in the System.ini file.

### Syntax

```
ReplaceProfString ( szFileName, szSectionName, szKeyName, szOrigValue, szReplaceValue );
```

## Parameters

**Table 66** ▪ ReplaceProfString Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>     | Specifies the name of the .ini file in which the profile string is to be replaced. If the file name is unqualified (that is, if a drive designation and path are <i>not</i> included), InstallShield searches for the file in the Windows folder. If the file does not exist, it is created in the specified folder; if a path is not included in file name, the file is created in the Windows folder. Note that if the file name is qualified with a path that does not exist, ReplaceProfString will fail. |
| <b>szSectionName</b>  | Specifies the name of the .ini file section to search for szKeyName. The section name should <i>not</i> be enclosed within delimiting brackets ( [ ] ). The search for this name is <i>not</i> case sensitive.                                                                                                                                                                                                                                                                                                |
| <b>szKeyName</b>      | Specifies the name of the key to replace. If the key does not exist, it is created.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szOrigValue</b>    | Specifies the current value of the key specified by szKeyName.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>szReplaceValue</b> | Specifies the new value to assign to szKeyName. The value of this parameter will appear to the right of the equal sign in the profile string (szKeyName = szValue).                                                                                                                                                                                                                                                                                                                                           |

## Return Values

**Table 67** ▪ ReplaceProfString Return Values

| Return Value  | Description                                                                    |
|---------------|--------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully replaced or added the profile string. |
| <b>&lt; 0</b> | Indicates that the function was unable to replace or add the profile string.   |

## Additional Information

Changes made to .ini files can be logged for uninstallation. However, there are some important restrictions to be

aware of. For more information, see [Uninstalling Initialization \(.ini\) File Entries](#).

## ReplaceProfString Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ReplaceProfString function.
*
* ReplaceProfString is called for the first time to replace
* the szKeyName key value szOrigValue with the value
* szReplaceValue. Then ReplaceProfString is called again to
* replace the newly set value of szKeyName, szReplaceValue,
* with szOrigValue.
*
* NOTE: In order for this script to run properly, you must set
*       the constant EXAMPLE_INI to reference an existing
*       initialization file on the target system. That file
*       should include the following lines:
*
*       [Old Section]
*       Old Key=Old value
*
*-----*/

#define EXAMPLE_INI "C:\\ISExempl.ini"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ReplaceProfString(HWND);

function ExFn_ReplaceProfString(hMSI)
    STRING szSectionName, szKeyName, szOrigValue, szReplaceValue;
begin

    szSectionName = "Old Section";
    szKeyName     = "Old Key";
    szOrigValue   = "Old value";
    szReplaceValue = "New value";

    // Replace szOrigValue with szReplaceValue.
    if (ReplaceProfString (EXAMPLE_INI, szSectionName, szKeyName, szOrigValue,
                          szReplaceValue) < 0) then
        MessageBox("ReplaceProfString failed.", SEVERE);
        abort;
    else
        sprintfBox (INFORMATION, "Replacement Successful",
                  "Original: %s\nNew:  %s", szOrigValue, szReplaceValue);
```

```

endif;

// Replace szReplaceValue with szOrigValue.
if (ReplaceProfString(EXAMPLE_INI, szSectionName, szKeyName, szReplaceValue,
                     szOrigValue) < 0) then;
    MessageBox("ReplaceProfString failed.", SEVERE);
else
    sprintfBox (INFORMATION, "Replacement Successful",
               "Original: %s\nNew: %s", szReplaceValue, szOrigValue);
endif;

end;

```

## ReplaceShortcut

The **ReplaceShortcut** function replaces a shortcut in a specified folder. You must specify an existing folder, either one that you have created with the [CreateShortcutFolder](#) function or one that already exists on the end user's system.

### Syntax

```

ReplaceShortcut (szShortcutFolder, szName, szNewItem, szCmdLine, szWorkingDir, szIconPath, nIcon,
                szShortCutKey, nFlag);

```

## Parameters

**Table 68** • ReplaceShortcut Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szShortcutFolder</b> | Specify the name of the folder that contains the shortcut that you want to replace.                                                                                                                                                                                                   |
| <b>szName</b>           | Specify the name of the shortcut that you want to replace.                                                                                                                                                                                                                            |
| <b>szNewItem</b>        | Specify the name of the shortcut as it should appear after the replacement.                                                                                                                                                                                                           |
| <b>szCmdLine</b>        | Specify one of the following: <ul style="list-style-type: none"> <li>• The fully qualified name of the executable file that is associated with the icon, including any command-line parameters.</li> <li>• The fully qualified path if szName is a subfolder.</li> </ul>              |
| <b>szWorkingDir</b>     | <p>If szName is not a subfolder, specify the directory that contains the product's program files.</p> <p>To make the directory that contains the product's program files the working directory, pass a null string ("" ) in this parameter.</p>                                       |
| <b>szIconPath</b>       | Specify the name of an alternate icon file or a valid executable file that contains the new icon.                                                                                                                                                                                     |
| <b>nlcon</b>            | If you specified an executable file for szIconPath, specify the icon index in the executable file. Otherwise, enter the number 0 for nlcon.                                                                                                                                           |
| <b>szShortCutKey</b>    | Specify the string that contains the shortcut key sequence the end user can press to start the program. For example, if you want the end user to be able to open the application by pressing the "Ctrl," the "Alt," and then the "1" key, specify "Ctrl + Alt + 1" in this parameter. |

**Table 68** • ReplaceShortcut Parameters (cont.)

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nFlag</b> | <p>Pass one or more of the following predefined constants in this parameter. To pass two or more predefined constants in this parameter, combine those constants with the bitwise OR operator (   ).</p> <ul style="list-style-type: none"> <li>● <b>CS_OPTION_FLAG_REPLACE_EXISTING</b>—Replace an existing shortcut.</li> <li>● <b>CS_OPTION_FLAG_RUN_MAXIMIZED</b>—The target of the shortcut is maximized when launched.</li> <li>● <b>CS_OPTION_FLAG_RUN_MINIMIZED</b>—The target of the shortcut is minimized when launched.</li> <li>● <b>CS_OPTION_FLAG_PREVENT_PINNING</b>—Do not allow the shortcut to be pinned to the Start menu or taskbar on Windows Vista or later systems. This option hides the context menu commands that enable end users to pin the shortcut to the taskbar and to the Start menu.<br/><br/>You may want to prevent pinning for shortcuts that are for tools and secondary products that are part of your installation.</li> <li>● <b>CS_OPTION_FLAG_NO_NEW_INSTALL_HIGHLIGHT</b>—Do not highlight the shortcut as newly installed after end users install your product on Windows Vista or later systems. This has the same effect as clearing the <b>Highlight newly installed programs</b> check box in the Customize Start Menu dialog box for an individual item on a target system.<br/><br/>You may want to use this option for shortcuts that are for tools and secondary products that are part of your installation.</li> <li>● <b>CS_OPTION_FLAG_NO_STARTSCREEN_PIN</b>—Do not pin the shortcut to the Start screen by default on Windows 8 target systems. If you pass this constant, the installation sets a Windows Shell property that was introduced in Windows 8.<br/><br/>You may want to prevent pinning for shortcuts that are for tools and secondary products that are part of your installation.</li> <li>● <b>NULL</b>—Indicates no options.</li> </ul> <p>For more information on CS_OPTION_FLAG_PREVENT_PINNING and CS_OPTION_FLAG_NO_STARTSCREEN_PIN, see the <a href="#">Additional Information section</a>.</p> |

## Return Values

**Table 69** ▪ ReplaceShortcut Return Values

| Return Value | Description                                                                                                                                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully replaced the shortcut.                                                                                                                                                                             |
| < 0          | Indicates that the function was unable to replace the shortcut.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

Note the following details about two of the nFlag constants.

### CS\_OPTION\_FLAG\_PREVENT\_PINNING

If you configure the shortcut to prevent pinning to the taskbar and the Start menu, the target of the shortcut is ineligible for inclusion in the most frequently used list on the Start menu.

Shortcuts that contain certain strings cannot be pinned to the taskbar or the Start menu, and they cannot be displayed in the most frequently used list. Examples are:

- Documentation
- Help
- Install
- Remove
- Setup
- Support

### CS\_OPTION\_FLAG\_NO\_STARTSCREEN\_PIN

Note that Windows 8 maintains information about shortcut pinning to the Start screen after a shortcut is removed by uninstalling the application. Therefore, the CS\_OPTION\_FLAG\_NO\_STARTSCREEN\_PIN constant has no effect on the target system if the shortcut has already been installed on it. Thus, when you are testing this functionality, ensure that you test on a clean machine—one on which this shortcut and its target have never been installed.

## ReplaceShortcut Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
```

```

* Demonstrates the ReplaceShortcut function.
*
* Note: In order for this script to run correctly, you must set
*       preprocessor constants to valid file names and a path
*       on the target system. To easily create this example
*       shortcut, run the CreateShortcut example 3.
*
\*-----*/

#define FOLDER      "C:\\Windows\\"
#define NEW_PROGRAM "C:\\WINDOWS\\WRITE.EXE"
#define NEW_PARAM   "C:\\WINDOWS\\README.TXT"

function OnFirstUIAfter()
    STRING szShortcutFolder, szName, szNewItem, szCmdLine, szWorkingDir;
    STRING szIconPath, szShortCutKey, szProgram, szParam;
    NUMBER nIcon, nFlag;
begin

    szShortcutFolder = FOLDER ^ "Example folder 3";
    szName           = "Notepad Example 3";
    szNewItem        = "New Wordpad Example";

    // Make sure the space is not seen as a delimiter.
    szProgram = NEW_PROGRAM;
    LongPathToQuote (szProgram, TRUE);

    szParam = NEW_PARAM;
    LongPathToShortPath(szParam);

    szCmdLine      = szProgram + " " + szParam;
    szWorkingDir   = "";
    szIconPath     = "";
    nIcon          = 0;
    szShortCutKey  = "";
    nFlag          = CS_OPTION_FLAG_REPLACE_EXISTING|CS_OPTION_FLAG_RUN_MAXIMIZED;

    // Display the folder on the screen.
    ShowProgramFolder (szShortcutFolder, SW_SHOW);

    // Replace the Notepad Example 3 shortcut with New Wordpad Example.
    if (ReplaceShortcut (szShortcutFolder, szName, szNewItem, szCmdLine,
                        szWorkingDir, szIconPath, nIcon, szShortCutKey,
                        nFlag) < 0) then
        MessageBox ("ReplaceShortcut failed.", SEVERE);
    else
        MessageBox ("Shortcut successfully replaced.", INFORMATION);
    endif;

end;

```

## Resize

The **Resize** function resizes an InstallScript array.

## Syntax

```
Resize ( Array , nNewSize );
```

## Parameters

**Table 70** ▪ Resize Parameters

| Parameter       | Description                                      |
|-----------------|--------------------------------------------------|
| <b>Array</b>    | Specifies the name of the array variable.        |
| <b>nNewSize</b> | Specifies the new size to be given to the array. |

## Return values

The **Resize** function returns the new size of the array.

# RGB

The **RGB** function creates a custom color value that can be used with [SetColor](#) and [SetTitle](#).

## Syntax

```
RGB ( constRed, constGreen, constBlue );
```

## Parameters

**Table 71** ▪ RGB Parameters

| Parameter         | Description                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>constRed</b>   | Specifies a numeric constant, ranging in value from 0 to 255, that indicates the amount of red in the custom color.   |
| <b>constGreen</b> | Specifies a numeric constant, ranging in value from 0 to 255, that indicates the amount of green in the custom color. |
| <b>constBlue</b>  | Specifies a numeric constant, ranging in value from 0 to 255, that indicates the amount of green in the custom color. |

## Return Values

This function returns a number value for a custom color that can be used when calling [SetColor](#) and [SetTitle](#).

## RGB Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the RGB function.
*
* The first call to RGB returns the value of the background
* color to Grey; the second call returns the background color
* to red; the third call returns the background color to blue.
* The values returned by the calls to RGB are passed to
* SetColor to change the background color.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_RGB(HWND);

function ExFn_RGB(hMSI)
begin

    Enable ( BACKGROUND );

    // Change the background color to light grey.
    SetColor (BACKGROUND, RGB(198,198,198));

    Delay (3);

    // Change the background color to red.
    SetColor (BACKGROUND, RGB(255,0,0));

    Delay (3);

    // Change the background color to blue.
    SetColor (BACKGROUND, RGB(0, 0, 255));

    Delay (3);

end;
```

# Built-In Functions (S-T)

For a list of functions by category, see [Built-In Functions by Category](#).

## SdAskDestPath

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdAskDestPath** function creates a dialog that allows the end user to select an alternate destination path. When the end user clicks Browse in this dialog, the [SelectDir](#) function is called to open a second dialog that enables the end user either to select an existing folder or to enter a new folder name.

### Syntax

```
SdAskDestPath ( szTitle, szMsg, svDir, nReserved );
```

## Parameters

**Table 1** • SdAskDestPath Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“Choose Folder”), pass a null string (“”) in this parameter.                                                                                                                                                                                                        |
| <b>szMsg</b>     | Specifies the text to display in the dialog. The text is considered a static control. Use the %P place holder in your message string to insert the product name (if any) that has been specified by a previous call to <a href="#">SdProductName</a> . To display the default instructions for this dialog, pass a null string (“”). |
| <b>svDir</b>     | Specifies the name of the directory to be selected by default. Returns the name of the directory selected by the end user.                                                                                                                                                                                                           |
| <b>nReserved</b> | Pass zero in this parameter. No other value is allowed.                                                                                                                                                                                                                                                                              |

## Return Values

**Table 2** • SdAskDestPath Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- If the end user specifies an incomplete, invalid, or write-protected path in the second dialog, an error message is displayed. If you want the end user to be able to select folders that are not writable, call the [AskPath](#) function instead.
- Setups that run in silent mode should create the new folder if it does not exist before calling SdAskDestPath. This ensures that the confirmation dialog is not displayed. Without this step, two response files are required to handle the two possible conditions.
- In earlier versions of InstallShield Professional, when the end user selected in the Choose Folder dialog a folder that did not exist, a confirmation message box was displayed asking whether the folder should be created. This message box proved to be confusing to many end users, so it has been removed from InstallShield.

## SdAskDestPath Example

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdAskDestPath function.
 *
 * SdAskDestPath is called to prompt the user for a path.
 * Then the selected path is assigned to the system variable
 * INSTALLDIR, which is displayed in a message box.
 *
 \*-----*/

#define TITLE_TEXT "SdAskDestPath Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

function OnBegin()
    STRING svDir;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set default folder name for call to SdAskDestPath.
    svDir = "C:\\ISEXamp1\\Target";

    // Display the SdAskDestPath dialog. Pass a null string
    // in the second parameter to display the default message.
    if (SdAskDestPath (TITLE_TEXT, "", svDir, 0) = NEXT) then
        INSTALLDIR = svDir;
    endif;

    // Display the new target directory.
    sprintfBox (INFORMATION, "SdAskDestPath", "Successful.\n\nThe Target " +
        "directory is: " + INSTALLDIR);

end;
```

## SdAskDestPath2

**Project** • This information applies to the following project types:

- *InstallScript*

- *InstallScript MSI*

The **SdAskDestPath** function creates a dialog that allows the end user to select an alternate destination path. When you click the Change button in that dialog, the **SelectDir** function is called to open a second dialog that enables the end user either to select an existing folder or to enter a new folder name.

## Syntax

```
SdAskDestPath2 ( szTitle, szMsg, svDir );
```

## Parameters

**Table 3** • SdAskDestPath2 Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of the dialog. To display the default title ("Choose Destination Location"), pass a null string ("") in this parameter.                                                                                                                                                                                 |
| <b>szMsg</b>   | Specifies the text to display in the dialog. The text is considered a static control. Use the %P place holder in your message string to insert the product name (if any) that has been specified by a previous call to <b>SdProductName</b> . To display the default instructions for this dialog, pass a null string (""). |
| <b>svDir</b>   | Specifies the name of the directory to be selected by default. Returns the name of the directory selected by the end user.                                                                                                                                                                                                  |

## Return Values

**Table 4** • SdAskDestPath2 Return Values

| Return Value              | Description                                       |
|---------------------------|---------------------------------------------------|
| <b>NEXT</b>               | Indicates that the user selected the Next button. |
| <b>BACK</b>               | Indicates that the user selected the Back button. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the dialog could not be displayed. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- If the end user specifies an incomplete, invalid, or write-protected path in the second dialog, an error message is displayed. If you want the end user to be able to select folders that are not writable, call the **AskPath** function instead.
- Installations that run in silent mode should create the new folder if it does not exist before calling **SdAskDestPath2**. This ensures that the confirmation dialog is not displayed. Without this step, two response files are required to handle the two possible conditions.

## SdAskDestPath2 Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdAskDestPath2 function.
 *
 * SdProductName is called to set the product name so that it
 * can be displayed in place of the %P placeholder in the
 * SdAskDestPath2 dialog. Then, SdAskDestPath2 is called to
 * prompt the user for a path. Finally, the selected path
 * is assigned to the system variable TARGETDIR, which is
 * displayed in a message box.
 *
 \*-----*/

#define TITLE_TEXT "SdAskDestPath2 Example"

    STRING svDir;

#include "ifx.h"

function OnBegin()
begin

    // Set product name.
    SdProductName ("Example Product 5.2");

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set default folder name for call to SdAskDestPath2.
    svDir = "C:\\ISEXampl\\Target";

    // Display the SdAskDestPath2 dialog. Pass a null string
    // in the second parameter to display the default message.
    if (SdAskDestPath2 (TITLE_TEXT, "", svDir ) = NEXT) then
        TARGETDIR = svDir;
    endif;

    // Display the new target directory.
    sprintfBox (INFORMATION, "SdAskDestPath2", "Successful.\n\nThe Target " +
        "directory is: " + TARGETDIR);

end;
```

# SdAskOptions

---

**Project** ▪ *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The **SdAskOptions** function creates a dialog that offers installation options. You can use check boxes or option buttons as the selection mechanism. The information shown beside the button is retrieved from a group of options. The default number of options is four. You can add or subtract the number of options as necessary in the group.

## Syntax

```
SdAskOptions ( szTitle, szMsg1, szMsg2, szId, szFeatures, nExclusiveFlag );
```

## Parameters

**Table 5** • SdAskOptions Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>        | Specifies the title of the dialog. To display the default title (“Select Components”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                               |
| <b>szMsg1</b>         | Specifies a message to display in the dialog. This static field has an ID of 801. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                                                                                                                                                               |
| <b>szMsg2</b>         | Specifies a second message to display in the dialog. This static field has an ID of 802.                                                                                                                                                                                                                                                                                                                        |
| <b>szId</b>           | Specifies an alternate numeric dialog ID. Use only numeric IDs expressed in string form (for example, ID 13001 as “13001”). You can copy the SdAskOptions dialog resource, make limited changes to it, give it a unique numeric ID, and call that dialog by passing its ID as a string in szId. (See above.) To create the standard four-option SdAskOptions dialog, pass a null string (“”) in this parameter. |
| <b>szFeatures</b>     | <p>Specifies the name of the feature that contains the subfeatures to be displayed. The subfeatures are preceded by check boxes or option buttons. To display all top-level features, pass a null string (“”) in this parameter.</p> <p>SdAskOptions searches for the requested features in the file media library or script-created feature set specified by the system variable <b>MEDIA</b>.</p>             |
| <b>nExclusiveFlag</b> | <p>Specifies the type of button you want to display in the dialog. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>EXCLUSIVE</b>—Specifies option buttons.</li> <li>● <b>NONEXCLUSIVE</b>—Specifies check boxes.</li> </ul>                                                                                                                   |

## Return Values

**Table 6** • SdAskOptions Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

- If your setup includes required, visible components, do not call SdAskOptions to obtain installation options. Instead, call FeatureDialog, SdFeatureDialog, SdFeatureDialogAdv, SdFeatureMult, or SdAskOptionsList in nonexclusive mode.
- If your setup does not use a setup type dialog, you must call FeatureSetupTypeSet to specify a setup type that has been defined in the IDE's Setup Types view before calling SdAskOptions.
- SdAskOptions operates on the current media, which is specified by the system variable MEDIA. During setup initialization, the installation assigns to MEDIA a media name that is associated with your file media library (Data1.cab).

**Task****To display script-created features:**

1. Save the current value of MEDIA in a string variable, for example, szSaveMEDIAValue.
2. Assign to MEDIA the name of the script-created component set.
3. Call SdAskOptions to get end-user selections.
4. Assign to MEDIA the value that you saved in step 1. You must do this before calling FeatureTransferData.

You can create more than one dialog of the SdAskOptions type by copying the SdAskOptions dialog resource (located in \_isres.dll) using a resource editor, making limited changes to the copy, and giving it a unique ID. You should save the copy to \_isuser.dll. When you call SdAskOptions and pass the ID of the customized copy of the dialog in the parameter szId, the customized copy is displayed. Limit your changes to editing existing static text fields and adding static text fields. Adding controls that require handling is not recommended because it requires changing the SdAskOptions source script.

## SdAskOptions Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SdAskOptions function
*
* This script displays a dialog that offers installation
* options.
*
* Note: To run this example script, create a project (or
*       insert into a project) with several features and/or
*       subfeatures.
*
\*-----*/
```

```
// Specify your feature name here. These are the names you gave to your
// features in the IDE. A NULL ("") string specifies base features.
```

```

#define FEATURE            ""
#define SDASKOPTSTITLE     "Component Selection"
#define SDASKOPTSMMSG1     "Select components to install."
#define SDASKOPTSMMSG2     "Your selections will be used to effect file transfer."
#define APPBASE_PATH       "Your Company Name\\Your Product Name"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "ifx.h"

function OnFirstUIBefore()
begin

    // Set a default destination path.
    INSTALLDIR = PROGRAMFILES ^ APPBASE_PATH;

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Get installation options.
    SdAskOptions (SDASKOPTSTITLE, SDASKOPTSMMSG1, SDASKOPTSMMSG2,
                  "", FEATURE, NONEXCLUSIVE);

end;

```

## SdAskOptionsList

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdAskOptionsList** function creates a dialog that displays a list of features for a custom installation.

### Syntax

```
SdAskOptionsList ( szTitle, szMsg, szFeatures, nStyle );
```

## Parameters

**Table 7** • SdAskOptionsList Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title (“Select Components”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>szMsg</b>      | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szFeatures</b> | <p>Specifies the name of the feature that contains the subfeatures to be displayed. The subfeatures are preceded by check boxes or option buttons. To display all top-level features, pass a null string (“”) in this parameter.</p> <p>SdAskOptionsList searches for the requested feature(s) in the file media library or script-created feature set specified by the system variable <b>MEDIA</b>.</p>                                                                                                                                                                                                              |
| <b>nStyle</b>     | <p>Specifies whether the end user's selection is limited. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>EXCLUSIVE</b>—Allows the end user to select only one item from the list. Do not use EXCLUSIVE mode if any of szFeatures' subfeatures are required features.</li> <li>● <b>NONEXCLUSIVE</b>—Allows the end user to select more than one item from the list, including multiple non-contiguous selections. Also displays two buttons—Select All and Clear All—which allow selection of all options or clearing of all selections.</li> </ul> |

## Return Values

**Table 8** • SdAskOptionsList Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- If your setup does not use a setup type dialog, you *must* call FeatureSetupTypeSet to specify a setup type that has been defined in the IDE's Setup Types view before calling SdAskOptionsList.
- SdAskOptionsList operates on the current media, which is specified by the system variable **MEDIA**. During setup initialization, the installation assigns to **MEDIA** a media name that is associated with your file media library (Data1.cab).

**Task****To display script-created features:**

1. Save the current value of MEDIA in a string variable, for example, szSaveMEDIAValue.
2. Assign to MEDIA the name of the script-created component set.
3. Call SdAskOptionsList to get end-user selections.
4. Assign to MEDIA the value that you saved in step 1. You must do this before calling FeatureTransferData.

## SdAskOptionsList Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdAskOptionsList function with the
 * NONEXCLUSIVE and EXCLUSIVE options.
 *
 \*-----*/

// Define strings. In a real setup you would define these in your string
// tables and precede each constant with @ to use them in your script.
#define COMP_SELECT_TITLE          "Select Components"
#define COMP_SELECT_MSG            "Select components to install."
#define MY_FEATURE_NAME "DefaultFeature"

#include "ifx.h"

function OnFirstUIBefore()
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Let user select from top-level components, nonexclusively.
    SdAskOptionsList(COMP_SELECT_TITLE, COMP_SELECT_MSG + " NONEXCLUSIVE", "", NONEXCLUSIVE);

    // Let user select from subcomponents of MY_FEATURE_NAME, exclusively.
    SdAskOptionsList(COMP_SELECT_TITLE, COMP_SELECT_MSG + " EXCLUSIVE", MY_FEATURE_NAME, EXCLUSIVE);

end;
```

# SdBitmap

---

**Project** ▪ *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The **SdBitmap** function displays a bitmap on a dialog. The maximum allowable size of the bitmap is 440 pixels wide by 275 pixels high. You can also display a message in the SdBitmap dialog, but only if you use a resource editor to modify the SdBitmap dialog resource so that the control that displays the message is made visible.

## Syntax

```
SdBitmap ( szTitle, szMsg, szBitmap );
```

## Parameters

**Table 9** • SdBitmap Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>  | Specifies the title of the dialog. To display the default title ("Welcome"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>szMsg</b>    | Pass a null string ("") in this parameter unless you use a resource editor to modify the SdBitmap dialog to display a message. See the Additional Information section, below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>szBitmap</b> | <p>Specifies the file name of the bitmap to display and, optionally, a set of bitmap attributes. If bitmap attributes are included, the string passed in this parameter should be formatted as follows:</p> <pre>"bitmap file name;transparent flag;3-D flag;Background color"</pre> <ul style="list-style-type: none"> <li>• <b>bitmap file name</b>—Specifies the name of the bitmap file. If the file name is unqualified (that is, if it does not include a drive designation and path), InstallShield searches for the bitmap in <a href="#">SUPPORTDIR</a>.</li> <li>• <b>transparent flag</b>—Indicates whether to display the bitmap transparently. When this flag is 1 (true), all portions of the bitmap that are magenta (RGB Value: 255,0,255) will be displayed transparently. The default for this parameter is 0 (non-transparent).</li> <li>• <b>3-D flag</b>—Indicates whether to add a 3-D border around the edges of the static field that contains the bitmap. The default for this parameter is 0 (no 3D border).</li> <li>• <b>background color</b>—Indicates the color to use for the background of the static text field. Note that this color will be visible only if the bitmap is smaller than the static text field in which it appears or if the transparent flag is set to 1 and the bitmap has transparent areas. The background color must be expressed as an RGB value, that is, as three numeric values separated by commas.</li> </ul> <p>The following example displays the bitmap from the file MyBitmap.bmp, which is located in the SUPPORTDIR folder. The bitmap is displayed on a black background and has a three-dimensional border. Any parts of the bitmap that are magenta are displayed in the background color of black.</p> <pre>"MyBitmap.bmp;1;1;0,0,0"</pre> |

## Return Values

**Table 10** • SdBitmap Return Values

| Return Value    | Description                                          |
|-----------------|------------------------------------------------------|
| <b>NEXT (1)</b> | Indicates that the end user clicked the Next button. |

**Table 10** ▪ SdBitmap Return Values (cont.)

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

You can use a resource editor to modify the SdBitmap dialog resource so that a message string passed as the parameter szMsg is displayed in the SdBitmap dialog.

The SdBitmap dialog resource is contained in \_isres.dll. The resource contains a static text control that receives the string passed as the parameter szMsg. However, by default this static text control is out of view in the SdBitmap dialog (below the dialog). SdBitmap also uses a static text control to display the bitmap image. You can resize the bitmap image static text control and move the message static text control into view in the dialog. The message in szMsg will then be visible when SdBitmap is called.

Be aware that changing the size of the bitmap image static text control may affect the display of your bitmap image. The bitmap image must be small enough to avoid being clipped when SdBitmap centers it in the bitmap image static text control.

This function does not support transparent bitmaps. If you use a transparent bitmap with this function, the transparent portions are displayed normally.

Metafiles are not supported by SdBitmap.

## SdBitmap Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdBitmap function.
 *
 * Note: Before running this script, set the defined constant
 *       BITMAP_FILE so that it references a bitmap file
 *       included in the Support Files/Billboards view.
 *
 \*-----*/

// The bitmap to display.
#define BITMAP_FILE SUPPORTDIR ^ "MyBitmap.bmp"

// The title to use for the SdBitmap dialog.
#define TITLE_TEXT "SdBitmap Example"

#include "Ifx.h"
```

```
function OnBegin()
begin
    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Display the specified bitmap in a dialog. Pass a
    // null string in the second parameter because the dialog
    // has not been customized to display a message,
    SdBitmap (TITLE_TEXT, "", BITMAP_FILE);

end;
```

## SdConfirmNewDir

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdConfirmNewDir** function creates a dialog that displays a folder name and prompts for confirmation. If the end user clicks the Yes button, this function creates the new folder automatically.

### Syntax

```
SdConfirmNewDir ( szTitle, szDir, nReserved );
```

## Parameters

**Table 11** ▪ SdConfirmNewDir Parameters

| Parameter        | Description                                                                                                                        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“Confirm New Folder”), pass a null string (“”) in this parameter. |
| <b>szDir</b>     | Specifies the name of the directory to confirm. (Obtain this information by calling SdAskDestPath.)                                |
| <b>nReserved</b> | Pass zero in this parameter. No other value is allowed.                                                                            |

## Return Values

**Table 12** ▪ SdConfirmNewDir Return Values

| Return Value   | Description                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------|
| <b>YES (1)</b> | Indicates that the Yes button was clicked. The directory has been confirmed and will be created.   |
| <b>NO (0)</b>  | Indicates that the No button was clicked. The specified directory will not be created.             |
| <b>&lt; 0</b>  | Indicates that the Yes button was clicked but the function was unable to create the new directory. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- The dialog that is displayed by this function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## SdConfirmNewDir Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdConfirmNewDir function.
```

```

*
* This example script first calls SdAskDestPath to get the
* destination folder from the user. If the folder does not
* exist, SdConfirmNewDir is then called to ask if the user
* wants to create the folder.
*
* Note: This script creates directories on the local hard disk.
*
\*-----*/

#define DEFAULT_TARGET_FOLDER "C:\\NONEXIST\\DIR";
#define TITLE_TEXT "SdConfirmNewDir Example"

#include "ifx.h"

function OnBegin()
    NUMBER nResult;
    STRING szMsg, svDir;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

start:
    // Set up parameters for call to SdAskDestPath.
    szMsg = "Select destination folder:";
    svDir = DEFAULT_TARGET_FOLDER

    // Retrieve destination folder from user.
    nResult = SdAskDestPath (TITLE_TEXT, szMsg, svDir, 0);

    // Check if the selected folder exists.
    if (ExistsDir (svDir) = EXISTS) then
        // Inform user that the specified folder already exists.
        szMsg = "folder '%s' already exists.\n\nIn order for this example to " +
            "run properly, please specify a nonexisting folder.";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svDir);

        // Start over.
        goto start;
    else
        // The specified folder does not exist. Request user
        // confirmation to create it.
        nResult = SdConfirmNewDir (TITLE_TEXT, svDir, 0);

        if (nResult = NO) then
            // The user did not want it created select.
            MessageBox ("Selected folder was not created.", INFORMATION);

            // Start over.
            goto start;
        elseif (nResult = YES) then
            // The user wants to create the folder.
            sprintfBox (INFORMATION, TITLE_TEXT, "%s created.", svDir);
        elseif (nResult < 0) then
            // Report the error; then terminate.

```

```
        MessageBox ("SdConfirmNewDir failed.", SEVERE);  
        abort;  
    endif;  
endif;  
  
end;
```

## SdConfirmRegistration

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdConfirmRegistration** function creates a message box that displays the User Name, Company Name, and Serial Number. If a null string ("" ) is entered in any field in the dialog, the displayed field will be empty.

### Syntax

```
SdConfirmRegistration ( szTitle, szName, szCompany, szSerial, nReserved );
```

## Parameters

**Table 13** ▪ SdConfirmRegistration Parameters

| Parameter        | Description                                                                                                                               |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“Registration Confirmation”), pass a null string (“”) in this parameter. |
| <b>szName</b>    | Specifies the end user's name.                                                                                                            |
| <b>szCompany</b> | Specifies the company name.                                                                                                               |
| <b>szSerial</b>  | Specifies the serial number. If this parameter contains a null string (“”), the serial number field is not displayed in the dialog.       |
| <b>nReserved</b> | Pass zero in this parameter. No other value is allowed.                                                                                   |

## Return Values

**Table 14** ▪ SdConfirmRegistration Return Values

| Return Value   | Description                                |
|----------------|--------------------------------------------|
| <b>YES (1)</b> | Indicates that the Yes button was clicked. |
| <b>NO (0)</b>  | Indicates that the No button was clicked.  |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- The dialog that is displayed by this function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.
- To obtain the serial number and end user's name and company, call **SdRegisterUserEx**. To obtain only the end user's name and company, call **SdRegisterUser**.

## SdConfirmRegistration Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
*
* InstallShield Example Script
*
```

```

* Demonstrates the SdRegisterUser and SdConfirmRegistration
* functions.
*
* SdRegisterUser is called to prompt for the user's name
* and company name. These entries are then confirmed when
* SdConfirmRegistration is called.
*
/*-----*/

#define REG_TITLE      "SdRegisterUser Example"
#define REG_MSG        "Please register your product now."
#define CONFIRM_TITLE  "SdConfirmRegistration Example"

#include "Ifx.h"

function OnBegin()
    STRING  svName, svCompany;
    NUMBER  nResult;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    repeat
        // Get the user's name and company name.
        SdRegisterUser (REG_TITLE, REG_MSG, svName, svCompany);

        // Confirm that the information is correct. Pass a null string in
        // parameter four since SdRegisterUser does not get a serial number.
        nResult = SdConfirmRegistration (CONFIRM_TITLE, svName, svCompany, "", 0);
    until nResult = YES;

end;

```

## SdCustomerInformation

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdCustomerInformation** function displays a dialog that enables the end user to specify the user name and company name for the product being installed. The dialog may also include radio buttons that let the end user specify whether the product should be installed for all users or only the current user.

You can specify default values for these fields by specifying the appropriate parameters. If you specify a null string (""), the function uses the appropriate script variable.

The Next button becomes enabled only when data exists in both edit fields. The end user cannot leave any field blank.

## Syntax

```
SdCustomerInformation ( szTitle, svName, svCompany, bvAllUsers );
```

## Parameters

**Table 15** ▪ SdCustomerInformation Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“Customer Information”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>svName</b>    | <p>Specifies the default value for the Name edit field when the function is called.</p> <p>If a null string (“”) is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDOWNER</b> variable. For an InstallScript project, this variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode. For an InstallScript MSI project, the default value of the variable is always read from the Windows Installer property <b>USERNAME</b>.</p> <p>The function returns the value that the end user specified in this parameter. In an InstallScript installation, the function also sets the value of <b>IFX_PRODUCT_REGISTEREDOWNER</b> to the value that the end user specified. In an InstallScript MSI installation, the function automatically updates the Windows Installer property <b>USERNAME</b>.</p>              |
| <b>svCompany</b> | <p>Specifies the default value for the Company edit field when the function is called.</p> <p>If a null string (“”) is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDCOMPANY</b> variable. For an InstallScript project, this variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode. For an InstallScript MSI project, the default value of the variable is always read from the Windows Installer property <b>COMPANYNAME</b>.</p> <p>The function returns the value that the end user specified in this parameter. In an InstallScript installation, the function also sets the value of <b>IFX_PRODUCT_REGISTEREDCOMPANY</b> to the value that the end user specified. In an InstallScript MSI installation, the function automatically updates the Windows Installer property <b>COMPANYNAME</b>.</p> |

**Table 15** ▪ SdCustomerInformation Parameters (cont.)

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bvAllUsers</b> | <p>Returns which option the end user selected. After the function returns, bvAllUsers is set to one of the following values:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—The <b>Anyone who uses this computer [all users]</b> option is selected.<br/> <p>If the end user selects this option in an InstallScript installation, the function sets the system variable <b>ALLUSERS</b> to a non-zero value.</p> <p>If the end user selects this option in an InstallScript MSI installation, the function sets the ALLUSERS property to a value of 2.</p> </li> <li>● <b>FALSE</b>—The <b>Only for me [user name]</b> option is selected.<br/> <p>If the end user selects this option in an InstallScript installation, the function sets the ALLUSERS variable to FALSE.</p> </li> </ul> <p>The default option is not based on the current value of the bvAllUsers parameter, but on the ALLUSERS Windows Installer property in an InstallScript MSI installation, or on the ALLUSERS system variable in an InstallScript installation:</p> <ul style="list-style-type: none"> <li>● If the ALLUSERS property is 2 or the ALLUSERS system variable is non-zero, the all-users option is selected by default.</li> <li>● If the <b>ALLUSERS</b> property is 1 or the ALLUSERS system variable is FALSE, the per-user option is selected by default.</li> </ul> <p>One or both of the radio buttons can be disabled or hidden by updating script variables as follows:</p> <ul style="list-style-type: none"> <li>● <b>DISABLE_PERUSERBTN</b>—Indicates that the per-user option should be disabled (or hidden if HIDE_DISABLED_BTNS is TRUE) in cases where it would normally be enabled. The default value of this variable is FALSE. Note that the per-user option is always hidden on Windows 9x platforms, regardless of the value of this variable.</li> <li>● <b>DISABLE_ALLUSERBTN</b>—Indicates that the all-users option should be disabled (or hidden) in cases where it would normally be enabled. The default value of this variable is FALSE. Note that the all-users option is always hidden if the installation is being run without administrator or power-user privileges, regardless of the value of this variable.</li> <li>● <b>HIDE_DISABLED_BTNS</b>—Indicates that both options should be hidden instead of being disabled. The default value of this variable is TRUE. Note that when this variable is set to TRUE, both options are hidden if either option is determined to be disabled.</li> </ul> |

## Return Values

**Table 16** ▪ SdCustomerInformation Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdCustomerInformation Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdCustomerInformation function.
 * SdCustomerInformation prompts the end user to enter a user
 * name and company name, and to specify whether the installation is
 * for anyone who uses the target system or for the current user only.
 *
 \*-----*/

#include "ifx.h"

function OnFirstUIBefore( )
    // ...other variable declarations...
    STRING  svName, svCompany, szMsg;
    NUMBER  nvUser, nReturn;
begin

    // ...show other dialogs...

    // get the end user's name and company name
    SdCustomerInformation("", svName, svCompany, nvUser);

    if (nvUser = 0) then
        szMsg = "per-user installation";
    else
        szMsg = "all-users installation";
    endif;

```

```

    MessageBox("You entered:\n\n" +
        "Name: " + svName + "\n" +
        "Company: " + svCompany + "\n" +
        "Type: " + szMsg,
        INFORMATION);

// ...other dialogs...

end;

```

## SdCustomerInformationEx

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdCustomerInformationEx** function displays a dialog that enables the end user to specify the user name, company name, and serial number for the product being installed. The dialog may also include radio buttons that let the end user specify whether the product should be installed for all users or only the current user.

You can specify default values for these fields by specifying the appropriate parameters. If you specify a null string (""), the function uses the appropriate script variable.

The Next button becomes enabled only when data exists in all three edit fields. The end user cannot leave any field blank.

**Note** ▪ The **SdCustomerInformationEx** function does not verify the serial number. To learn how to add code that verifies the serial number, see the sample serial number validation project. This sample project is in one of the Samples subfolders within the InstallShield Program Files folder. The default installation location is C:\Program Files\InstallShield\2022\Samples\InstallScript\Serial Number Validation Sample Project.

### Syntax

```
SdCustomerInformationEx ( szTitle, svName, svCompany, svSerial, bvAllUsers );
```

## Parameters

**Table 17** ▪ SdCustomerInformationEx Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“Customer Information”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>svName</b>    | <p>Specifies the default value for the Name edit field when the function is called.</p> <p>If a null string (“”) is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDOWNER</b> variable. For an InstallScript project, this variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode. For an InstallScript MSI project, the default value of the variable is always read from the Windows Installer property <b>USERNAME</b>.</p> <p>The function returns the value that the end user specified in this parameter. In an InstallScript installation, the function also sets the value of <b>IFX_PRODUCT_REGISTEREDOWNER</b> to the value that the end user specified. In an InstallScript MSI installation, the function automatically updates the Windows Installer property <b>USERNAME</b>.</p>              |
| <b>svCompany</b> | <p>Specifies the default value for the Company edit field when the function is called.</p> <p>If a null string (“”) is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDCOMPANY</b> variable. For an InstallScript project, this variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode. For an InstallScript MSI project, the default value of the variable is always read from the Windows Installer property <b>COMPANYNAME</b>.</p> <p>The function returns the value that the end user specified in this parameter. In an InstallScript installation, the function also sets the value of <b>IFX_PRODUCT_REGISTEREDCOMPANY</b> to the value that the end user specified. In an InstallScript MSI installation, the function automatically updates the Windows Installer property <b>COMPANYNAME</b>.</p> |
| <b>svSerial</b>  | <p>Specifies the default value for the Serial Number edit field when the function is called.</p> <p>If a null string (“”) is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDSERIALNUM</b> variable. This variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode.</p> <p>The function returns the value that the end user specified in this parameter. The function also sets the value of <b>IFX_PRODUCT_REGISTEREDSERIALNUM</b> to the value that the end user specified.</p>                                                                                                                                                                                                                                                                                                                              |

**Table 17** ▪ SdCustomerInformationEx Parameters (cont.)

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bvAllUsers</b> | <p>Returns which option the end user selected. After the function returns, bvAllUsers is set to one of the following values:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—The <b>Anyone who uses this computer [all users]</b> option is selected.<br/> <p>If the end user selects this option in an InstallScript installation, the function sets the system variable <b>ALLUSERS</b> to a non-zero value.</p> <p>If the end user selects this option in an InstallScript MSI installation, the function sets the ALLUSERS property to a value of 2.</p> </li> <li>● <b>FALSE</b>—The <b>Only for me [user name]</b> option is selected.<br/> <p>If the end user selects this option in an InstallScript installation, the function sets the ALLUSERS variable to FALSE.</p> </li> </ul> <p>The default option is not based on the current value of the bvAllUsers parameter, but on the ALLUSERS Windows Installer property in an InstallScript MSI installation, or on the ALLUSERS system variable in an InstallScript installation:</p> <ul style="list-style-type: none"> <li>● If the ALLUSERS property is 2 or the ALLUSERS system variable is non-zero, the all-users option is selected by default.</li> <li>● If the <b>ALLUSERS</b> property is 1 or the ALLUSERS system variable is FALSE, the per-user option is selected by default.</li> </ul> <p>One or both of the radio buttons can be disabled or hidden by updating script variables as follows:</p> <ul style="list-style-type: none"> <li>● <b>DISABLE_PERUSERBTN</b>—Indicates that the per-user option should be disabled (or hidden if HIDE_DISABLED_BTNS is TRUE) in cases where it would normally be enabled. The default value of this variable is FALSE. Note that the per-user option is always hidden on Windows 9x platforms, regardless of the value of this variable.</li> <li>● <b>DISABLE_ALLUSERBTN</b>—Indicates that the all-users option should be disabled (or hidden) in cases where it would normally be enabled. The default value of this variable is FALSE. Note that the all-users option is always hidden if the installation is being run without administrator or power-user privileges, regardless of the value of this variable.</li> <li>● <b>HIDE_DISABLED_BTNS</b>—Indicates that both options should be hidden instead of being disabled. The default value of this variable is TRUE. Note that when this variable is set to TRUE, both options are hidden if either option is determined to be disabled.</li> </ul> |

## Return Values

**Table 18** • SdCustomerInformationEx Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdCustomerInformationEx Example

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 *  InstallShield Example Script
 *
 *  Demonstrates the SdCustomerInformationEx function.
 *  SdCustomerInformationEx prompts the end user to enter a user
 *  name, company name, and serial number, and to specify whether
 *  the installation is for anyone who uses the target system
 *  or for the current user only.
 *
 \*-----*/

#include "ifx.h"

function OnFirstUIBefore( )
    // ...other variable declarations...
    STRING  svName, svCompany, svSerial, szMsg;
    NUMBER  nvUser, nReturn;
begin

    // ...show other dialogs...

    // get the end user's name and company name
    SdCustomerInformationEx("", svName, svCompany, svSerial, nvUser);

    if (nvUser = 0) then
        szMsg = "per-user installation";
    else
        szMsg = "all-users installation";
    endif;

```

```

        MessageBox("You entered:\n\n" +
            "Name: " + svName + "\n" +
            "Company: " + svCompany + "\n" +
            "Serial number: " + svSerial + "\n" +
            "Type: " + szMsg,
            INFORMATION);

// ...other dialogs...

end;

```

## SdDiskSpace2

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdDiskSpace2** function displays a dialog that shows either of the following:

- A list view of volumes, required space, available space, and the difference between available space and required space.
- A warning message indicating that the target system does not have enough available space for the installation to take place. The dialog also displays a list view of volumes, required space, available space, and the difference between available space and required space.

The **SdDiskSpace2** function supersedes the **SdDiskSpaceRequirements** and **SdOutOfDiskSpace** functions.

### Syntax

```
SdDiskSpace2 (szTitle, szMsg, bUseOutOfSpaceDialog);
```

## Parameters

**Table 19** ▪ SdDiskSpace2 Parameters

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>              | Specifies the title of the dialog. To display the default title (“Disk Space Requirements” or “Out of Disk Space”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>szMsg</b>                | Specifies the message to display in the dialog. This text is considered a static control. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>bUseOutOfSpaceDialog</b> | <p>Indicates whether to show the dialog that warns that the installation is out of space or the dialog that shows the disk space requirements. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Show the dialog that displays a warning message indicating that the target system does not have enough available space for the installation to take place. The dialog also displays a list view of volumes, required space, available space, and the difference between available space and required space.</li> <li>● <b>FALSE</b>—Show the dialog that displays a list view of volumes, required space, available space, and the difference between available space and required space.</li> </ul> |

## Return Values

**Table 20** ▪ SdDiskSpace2 Return Values

| Return Value    | Description                                        |
|-----------------|----------------------------------------------------|
| <b>NEXT (1)</b> | Indicates that the end user clicked the OK button. |

## Additional Information

**Project** ▪ In InstallScript MSI installations, the *OnOutOfDiskSpace* event handler responds to the *Out Of Disk Space* event. The default implementation of *OnOutOfDiskSpace* displays the **SdDiskSpace2** dialog, and then aborts the installation.

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdDiskSpace2 Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdDiskSpace2 function.
 * SdDiskSpace2 displays a list view of volumes,
 * required space, available space, and the difference between
 * available and required space.
 *
 \*-----*/

#include "ifx.h"

function OnFirstUIBefore( )
begin

// ... show other dialogs ...

    // display the disk space requirements
    SdDiskSpace2 ("",
        "Review the available and required disk space " +
        "to determine where to install the application.",
        FALSE);

// ... other dialogs ...

end;

```

## SdDiskSpaceRequirements

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdDiskSpace2** function displays a list view of volumes, required space, available space, and the difference between available space and required space.

The **SdDiskSpace2** function supersedes the **SdDiskSpaceRequirements** function.

### Syntax

```
SdDiskSpaceRequirements (szTitle, szMsg);
```

## Parameters

**Table 21** ▪ SdDiskSpaceRequirements Parameters

| Parameter      | Description                                                                                                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of the dialog. To display the default title (“Disk Space Requirements”), pass a null string (“”) in this parameter.                                                   |
| <b>szMsg</b>   | Specifies the message to display in the dialog. This text is considered a static control. To display the default instructions for this dialog, pass a null string (“”) in this parameter. |

## Return Values

**Table 22** ▪ SdDiskSpaceRequirements Return Values

| Return Value    | Description                                        |
|-----------------|----------------------------------------------------|
| <b>NEXT (1)</b> | Indicates that the end user clicked the OK button. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

# SdDisplayTopics

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdDisplayTopics** function creates a dialog that displays information based on topic data. The dialog provides a heading and then topics of titles and descriptions. You can use this dialog to display Help topics, examples, and so on.

## Syntax

```
SdDisplayTopics ( szTitle, szMsg, listTopics, listDetails, nReserved );
```

## Parameters

**Table 23** ▪ SdDisplayTopics Parameters

| Parameter          | Description                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>     | Specifies the title of the dialog. To display the default title (“Custom Installation Help”), pass a null string (“”) in this parameter.        |
| <b>szMsg</b>       | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string (“”) in this parameter. |
| <b>listTopics</b>  | Specifies the string list that contains the topics to display.                                                                                  |
| <b>listDetails</b> | Specifies the string list that contains a description of each topic.                                                                            |
| <b>nReserved</b>   | Pass 0 (zero) in this parameter. No other value is allowed.                                                                                     |

## Return Values

**Table 24** ▪ SdDisplayTopics Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- In an InstallScript MSI installation, when the end user clicks Next the USERNAME and COMPANYNAME properties are set using the information contained in the svName and svCompany fields, respectively.
- You can modify the font style of description text to distinguish it from title (topic) text. The message and topic titles are always displayed in bold type.
- The message static field must have an ID of 801. The topic identifiers must have numbers in the range of 802 - 849. Description fields have an ID range of 851 - 899.
- The spacing of the static description fields is fixed by the size of the dialog. You cannot dynamically change the spacing in the listDetails list. If the number of topics and descriptions is less than the number of static fields, nothing appears in the white space, but the size of the dialog is not changed.

## SdDisplayTopics Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdDisplayTopics function.
 *
 * This example script creates two lists: one for topic titles,
 * one for topic descriptions. It then calls SdDisplayTopics to
 * display the topics and descriptions.
 *
 \*-----*/

#define TITLE_TEXT "SdDisplayTopics Example"
#define MSG_TEXT "Custom setup options let you choose which parts of YourApp to install."

#define TOPIC1 "YourApp Program:"
#define TOPIC2 "YourApp Help:"
#define TOPIC3 "YourApp Examples:"

#define DESC1 "Includes all the files to run and write YourApp."
#define DESC2 "A computer-based tutorial demonstrating how to create programs using YourApp."
#define DESC3 "Several examples applications created using YourApp."

#include "Ifx.h"

function OnBegin()
    LIST listDescriptions, listTopics;
begin

    // Create a list for topics.
    listTopics = ListCreate (STRINGLIST);

    // Create a list for topic descriptions.
    listDescriptions = ListCreate (STRINGLIST);

    if (listTopics = LIST_NULL) || (listDescriptions = LIST_NULL) then
        // Report the error; then terminate.
        MessageBox("Unable to create lists.", INFORMATION);
        abort;
    endif;

    // Build the list of topics.
    ListAddString (listTopics, TOPIC1, AFTER);
    ListAddString (listTopics, TOPIC2, AFTER);
    ListAddString (listTopics, TOPIC3, AFTER);

    // Build the list of topic descriptions.
    ListAddString (listDescriptions, DESC1, AFTER);
    ListAddString (listDescriptions, DESC2, AFTER);
    ListAddString (listDescriptions, DESC3, AFTER);

    // Display the topics and descriptions.
    SdDisplayTopics (TITLE_TEXT, MSG_TEXT, listTopics, listDescriptions, 0);

```

```
// Remove the lists from memory.  
ListDestroy (listTopics);  
ListDestroy (listDescriptions);  
  
end;
```

## SdExceptions

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdExceptions** function displays a message box that informs the end user that a shared, locked (in use), or read-only file has been encountered, and it offers appropriate options.

### Syntax

```
SdExceptions (nExceptionType, szFilename);
```

## Parameters

**Table 25** ▪ SdExceptions Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nExceptionType</b> | Specifies which type of file problem has been encountered. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>SHARED</b>—A shared file's reference count has been reduced to zero.</li> <li>● <b>READONLY</b>—A read-only file has been encountered.</li> <li>● <b>LOCKED</b>—A locked file has been encountered.</li> </ul> |
| <b>szFilename</b>     | Specifies the name of the file that caused the problem.                                                                                                                                                                                                                                                                                                                                 |

## Return Values

**Table 26** ▪ SdExceptions Return Values

| Return Value                          | Description                                       |
|---------------------------------------|---------------------------------------------------|
| <b>ERR_RETRY (4)</b>                  | Indicates that the Retry button was selected.     |
| <b>ERR_IGNORE (5)</b>                 | Indicates that the Ignore button was selected.    |
| <b>ERR_YES (6)</b>                    | Indicates that the Yes button was selected.       |
| <b>ERR_NO (7)</b>                     | Indicates that the No button was selected.        |
| <b>ERR_PERFORM_AFTER_REBOOT (100)</b> | Indicates that the Reboot button was selected.    |
| <b>&lt; 0</b>                         | Indicates that the dialog could not be displayed. |

## Additional Information

The dialog that is displayed by this function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## SdExceptions Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* The SdExceptions function displays a dialog informing the
* end user that a shared, locked (in use), or read-only file has
* been encountered and offering appropriate options.
*
* The SdExcpetions function is used in the default code
* for the following Miscellaneous event handlers:
*
*     OnFileLocked
*     OnFileReadOnly
*     OnRemovingSharedFile
*
* The sample script below uses the OnFileReadOnly event. To get
* the SdExceptions prompt, the setup must attempt to overwrite or
* uninstall a read-only file.
*
\*-----*/

#include "Ifx.h"

//-----
// OnFileReadOnly
//
// The OnFileReadOnly event is called when a read-only file needs to be
// installed or uninstalled.
//
// szFile will contain the full path of the file that is read-only when the
// event is called.
//
// The event should return one of the following values:
//
// ERR_YES - Indicates that the file should be installed or uninstalled,
//
// ERR_NO - Indicates that the file should not be installed or uninstalled.
//-----
function OnFileReadOnly(szFile)
begin
    // TODO: Enable this code if you want to return ERR_YES and simply
    // install or uninstall the read-only file w/o confirmation.
    // return ERR_YES;

    return SdExceptions(READONLY, szFile);
end;

```

## SdFeatureDialog

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFeatureDialog** function creates a dialog that displays a list of features in the setup that the user can install and the amount of disk space that each feature occupies. This function is identical to SdFeatureDialogAdv.

The end user can change the destination folder by clicking the Browse button and can check the available disk space on other drives by clicking the Disk Space button.

## Syntax

```
SdFeatureDialog ( szTitle, szMsg, svDir, szFeatures );
```

## Parameters

**Table 27** ▪ SdFeatureDialog Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title (“Select Features”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>szMsg</b>      | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>svDir</b>      | <p>Specifies the name of the folder to be selected by default and returns the name of the folder selected by the end user. The destination folder specified by svDir is not assigned automatically to INSTALLDIR, TARGETDIR, or any other system variable. To apply the value of svDir to the installation, you must assign it to INSTALLDIR (in an InstallScript MSI installation), TARGETDIR (in an InstallScript installation), or to a script-defined variable, if one is in use.</p> <p>If the default folder specified by svDir does not already exist on the end user's system, it is not created unless the end user clicks the Browse button and follows the steps to create it from the Choose Folder dialog. Therefore, whenever you specify a default folder, you must call <a href="#">ExistsDir</a> when FeatureDialog returns in order to determine whether that folder exists. If it does not exist, call <a href="#">CreateDir</a> to create it on the end user's system.</p> |
| <b>szFeatures</b> | <p>Specifies the name of the feature whose subfeatures are to be displayed. To display all top-level features, pass a null string (“”) in this parameter. To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a>.</p> <p>SdFeatureDialog searches for the requested features in the script-created feature set specified by the system variable <a href="#">MEDIA</a>; see the <a href="#">Additional Information</a> section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Return Values

**Table 28** ▪ SdFeatureDialog Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- A feature's size is displayed as 0 until it is selected. Once it has been selected, its actual size is displayed.

- The required disk space that is displayed by the dialog includes the size of the files that must be installed to enable maintenance and uninstallation. If all application components are deselected, the size of these files is still displayed.
- If your installation does not use a setup type dialog, you must call **FeatureSetupTypeSet** to specify a setup type that has been defined in the Setup Types view before calling **SdFeatureDialog**.
- **SdFeatureDialog** operates on the current media, which is specified by the system variable MEDIA. During setup initialization, the installation assigns to MEDIA a media name that is associated with your file media library (Data1.cab).

**Task****To display script-created features:**

1. Save the current value of MEDIA in a string variable, for example, szSaveMEDIAValue.
  2. Assign to MEDIA the name of the script-created component set.
  3. Call **SdFeatureDialog** to get end-user selections.
  4. Assign to MEDIA the value that you saved in step 1. You must do this before calling **FeatureTransferData**.
- If necessary, feature names are truncated to allow the display of the largest possible feature size. The space required to display the size depends on the maximum feature size (2 GB), the feature size options currently in use, and the font used to display feature information in the dialog. Feature size options are set with the **DialogSetInfo** function.

When the space required to display the maximum possible size has been determined, all feature names are truncated automatically, if necessary, to fit the remaining space. The name of a feature that requires less space to display its size (or that is not selected) may still be truncated under this method. To maximize performance and ensure that feature names appear complete, make feature names or display names smaller than the space available in the dialog.

- The Available Disk Space dialog cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.
- The Disk Space button has an ID of 101. This button automatically displays the available disk space dialog. You can remove this button/option if you prefer. The Directory static field requires an ID of 851. The list box ID has a multiple selection style.
- In installations that were created with early versions of InstallShield Professional, when the end user selected in the Choose Folder dialog a folder that did not exist, a confirmation message box was displayed asking whether the folder should be created. This message box proved to be confusing to many end users, so it has been removed from InstallShield.

## SdFeatureDialog Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdFeatureDialog function.
 *
 * This example script displays a dialog that displays a list
 * of features in the setup that the end user can install and the
 * amount of space that each feature occupies.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features
 *           and/or subfeatures with components containing
 *           files.
 *
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, svDir;
begin
    svDir    = TARGETDIR;
    szTitle = "Select Features";
    szMsg    = "Select the features you want to install on your computer.";

    // Display all top-level features available.
    SdFeatureDialog (szTitle, szMsg, svDir, "");

end;

```

## SdFeatureDialog2

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFeatureDialog2** function creates a dialog that displays the following:

- A list of features that the end user can install.
- The space required for the selected features and the space that is available in the destination location. A feature's size is displayed as the number 0 until it is selected. When the feature is selected, its actual size is displayed.
- A description of the selected feature—the value of the feature's Description setting.

If a particular feature has subfeatures, the Change button becomes active when the end user clicks the feature. Clicking the Change button launches the Select Subfeatures dialog, where the end user can make further selections.

## Syntax

```
SdFeatureDialog2 ( szTitle, szMsg, szDir, szFeatures );
```

## Parameters

**Table 29** ▪ SdFeatureDialog2 Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title (“Select Features”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>szMsg</b>      | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>szDir</b>      | <p>Specifies the name of the folder to be selected by default and returns the name of the folder selected by the end user. The destination folder specified by szDir is not assigned automatically to INSTALLDIR, TARGETDIR, or any other system variable. To apply the value of szDir to the installation, you must assign it to INSTALLDIR (in an InstallScript MSI installation), TARGETDIR (in an InstallScript installation), or to a script-defined variable, if one is in use.</p> <p>If the default folder specified by szDir does not already exist on the end user’s system, it is not created unless the end user clicks the Browse button and follows the steps to create it from the Choose Folder dialog. Therefore, whenever you specify a default folder, you must call <a href="#">ExistsDir</a> when <b>FeatureDialog</b> returns in order to determine whether that folder exists. If it does not exist, call <a href="#">CreateDir</a> to create it on the end user’s system.</p> |
| <b>szFeatures</b> | <p>Specifies the name of the feature whose subfeatures are displayed. To display all top-level features, pass a null string (“”) in this parameter. To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a>.</p> <p>SdFeatureDialog2 searches for the requested features in the script-created feature set specified by the system variable <a href="#">MEDIA</a>; see the <a href="#">Additional Information</a> section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Return Values

**Table 30** ▪ SdFeatureDialog2 Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

- Default selection settings are cleared when the end user selects a feature or subfeature displayed in the dialog. If the end user clears a feature selection, all of its subfeatures are cleared. Conversely, if the end user clears all of a feature's subfeature selections, the feature's selection is cleared.

When a feature is not selected by default, its subfeatures are not selected by default. If all subfeatures of a feature are not selected by default, the parent feature should not be selected by default. For information on default feature and subfeature selection settings, see [FeatureAddItem](#).

- A feature's size is displayed as the number 0 until it is selected. Once it has been selected, its actual size is displayed.
- The required disk space displayed by the dialog includes the size of the files that must be installed to enable maintenance setups and uninstallation. Even if all application components are deselected, the size of these files is still displayed.
- If your installation does not use a setup type dialog, you must call [FeatureSetupTypeSet](#) to specify a setup type that has been defined in the Setup Types view before calling **SdFeatureDialog2**.
- **SdFeatureDialog2** operates on the current media, which is specified by the system variable MEDIA. During setup initialization, the installation assigns to MEDIA a media name that is associated with your file media library (Data1.cab).

#### Task

#### To display script-created features:

1. Save the current value of MEDIA in a string variable, for example, szSaveMEDIAValue.
  2. Assign to MEDIA the name of the script-created component set.
  3. Call **SdFeatureDialog2** to get end-user selections.
  4. Assign to MEDIA the value that you saved in step 1. You must do this before calling [FeatureTransferData](#).
- If necessary, feature names are truncated to allow the display of the largest possible feature size. The space required to display the size depends on the maximum feature size (2 GB), the feature size options currently in use, and the font used to display feature information in the dialog. Feature size options are set with the [DialogSetInfo](#) function.

When the space required to display the maximum possible size has been determined, all feature names are truncated automatically, if necessary, to fit the remaining space. The name of a feature that requires less space to display its size (or that is not selected) may still be truncated under this method. To maximize performance and ensure that feature names appear complete, make feature names or display names smaller than the space available in the dialog.

- The Select Subfeatures dialog cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## SdFeatureDialog2 Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdFeatureDialog2 function.
 *
 * This example script displays a dialog that displays a list
 * of features in the setup that the end user can install and the
 * amount of space that each feature occupies.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features
 *           and/or subfeatures with components containing
 *           files.
 *
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, svDir;
begin
    svDir    = TARGETDIR;
    szTitle = "Select Features";
    szMsg    = "Select the features you want to install on your computer.";

    // Display all top-level features available.
    SdFeatureDialog2 (szTitle, szMsg, svDir, "");

end;

```

## SdFeatureDialogAdv

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFeatureDialogAdv** function creates a dialog that displays a list of features in the setup that the end user can install and the amount of disk space that each feature occupies. This function is identical to **SdFeatureDialog**.

The end user can change the destination folder by clicking the Browse button and can check the available disk space on other drives by clicking the Disk Space button.

### Syntax

```
SdFeatureDialogAdv ( szTitle, szMsg, svDir, szFeatures );
```

## Parameters

**Table 31** • SdFeatureDialogAdv Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title (“Select Features”), pass a null string ("" ) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szMsg</b>      | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("" ) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>svDir</b>      | <p>Specifies the name of the folder to be selected by default and returns the name of the folder selected by the end user. The destination folder specified by svDir is not assigned automatically to INSTALLDIR, TARGETDIR, or any other system variable. To apply the value of svDir to the setup, you must assign it to INSTALLDIR (in an InstallScript MSI installation), TARGETDIR (in an InstallScript installation), or to a script-defined variable, if one is in use.</p> <p>If the default folder specified by svDir does not already exist on the end user's system, it is not created unless the end user clicks the Browse button and follows the steps to create it from the Choose Folder dialog. Therefore, whenever you specify a default folder, you must call <a href="#">ExistsDir</a> when FeatureDialog returns in order to determine whether that folder exists. If it does not exist, call <a href="#">CreateDir</a> to create it on the end user's system.</p> |
| <b>szFeatures</b> | <p>Specifies the name of the feature whose subfeatures are to be displayed. To display all top-level features, pass a null string ("" ) in this parameter. To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a>.</p> <p>SdCFeatureDialogAdv searches for the requested features in the script-created feature set specified by the system variable <a href="#">MEDIA</a>; see the <a href="#">Additional Information</a> section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Return Values

**Table 32** • SdFeatureDialogAdv Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- A feature's size is displayed as 0 until it is selected. Once it has been selected, its actual size is displayed.

- The required disk space displayed by the dialog includes the size of the files that must be installed to enable maintenance setups and uninstallation. Even if all application components are deselected, the size of these files is still displayed.
- If your setup does not use a setup type dialog, you *must* call `FeatureSetupTypeSet` to specify a setup type that has been defined in the IDE's Setup Types view before calling `SdFeatureDialogAdv`.
- `SdFeatureDialogAdv` operates on the current media, which is specified by the system variable `MEDIA`. During setup initialization, the installation assigns to `MEDIA` a media name that is associated with your file media library (`Data1.cab`).

**Task****To display script-created features:**

1. Save the current value of `MEDIA` in a string variable, for example, `szSaveMEDIAValue`.
  2. Assign to `MEDIA` the name of the script-created component set.
  3. Call `SdFeatureDialogAdv` to get end-user selections.
  4. Assign to `MEDIA` the value that you saved in step 1. You must do this before calling `FeatureTransferData`.
- If necessary, feature names are truncated to allow the display of the largest possible feature size. The space required to display the size depends on the maximum feature size (2 GB), the feature size options currently in use, and the font used to display feature information in the dialog. Feature size options are set with the `DialogSetInfo` function.

When the space required to display the maximum possible size has been determined, all feature names are truncated automatically, if necessary, to fit the remaining space. The name of a feature that requires less space to display its size (or that is not selected) may still be truncated under this method. To maximize performance and ensure that feature names appear complete, make feature names or display names smaller than the space available in the dialog.

- The Available Disk Space dialog cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.
- The Disk Space... button has an ID of 101. This button automatically displays the available disk space dialog. You can remove this button/option if you prefer. The Directory static field requires an ID of 851. The list box ID has a multiple selection style.
- In earlier versions of InstallShield Professional, when the end user selected in the Choose Folder dialog a folder that did not exist, a confirmation message box was displayed asking whether the folder should be created. This message box proved to be confusing to many end users, so it has been removed from InstallShield.

## SdFeatureDialogAdv Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdFeatureDialogAdv function.
 *
 * This example script displays a dialog that displays a list
 * of features in the setup that the end user can install and the
 * amount of space that each feature occupies.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features
 *           and/or subfeatures with components containing
 *           files.
 *
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, svDir;
begin

    svDir  = TARGETDIR;
    szTitle = "Select Features";
    szMsg  = "Select the features you want to install on your computer.";

    // Display all top-level features available.
    SdFeatureDialogAdv (szTitle, szMsg, svDir, "");

end;

```

## SdFeatureMult

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFeatureMult** function creates a dialog that displays the following:

- A list of features and subfeatures that the end user can select for installation. The dialog has two feature lists. If the feature selected in the first list has subfeatures, the subfeatures are displayed in the second list.
- The disk space required for the selected features and the space available in the destination location. A feature's size is displayed as 0 until it is selected. When the end user selects a feature, its actual size is displayed.
- The description of a feature or subfeature. The end user can view the description by clicking on the feature or subfeature.

## Syntax

```
SdFeatureMult ( szTitle, szMsg, svDir, szFeatures );
```

## Parameters

**Table 33** • SdFeatureMult Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title (“Select Features”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>szMsg</b>      | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>svDir</b>      | <p>Specifies the name of the folder to be selected by default and returns the name of the folder selected by the end user. The destination folder specified by svDir is not assigned automatically to INSTALLDIR, TARGETDIR, or any other system variable. To apply the value of svDir to the setup, you must assign it to INSTALLDIR (in an InstallScript MSI installation), TARGETDIR (in an InstallScript installation), or to a script-defined variable, if one is in use.</p> <p>If the default folder specified by svDir does not already exist on the end user's system, it is not created unless the end user clicks the Browse button and follows the steps to create it from the Choose Folder dialog. Therefore, whenever you specify a default folder, you must call <a href="#">ExistsDir</a> when FeatureDialog returns in order to determine whether that folder exists. If it does not exist, call <a href="#">CreateDir</a> to create it on the end user's system.</p> |
| <b>szFeatures</b> | <p>Specifies the name of the feature whose subfeatures are displayed. To display all top-level features, pass a null string (“”) in this parameter. To learn how to refer to top-level features and subfeatures, see <a href="#">Specifying Features and Subfeatures in Function Calls</a>.</p> <p>SdFeatureMult searches for the requested features in the script-created feature set specified by the system variable <a href="#">MEDIA</a>; see the <a href="#">Additional Information</a> section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Return Values

**Table 34** • SdFeatureMult Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

- Default selection settings are cleared when the end user selects a feature or subfeature displayed in the dialog. If the end user clears a feature selection, all of its subfeatures are cleared. Conversely, if the end user clears all of a feature's subfeature selections, the feature's selection is cleared.

When a feature is not selected by default, its subfeatures are not selected by default. If all subfeatures of a feature are not selected by default, the parent feature should not be selected by default. See [FeatureAddItem](#) for information on default feature and subfeature selection settings.

- A feature's size is displayed as 0 until it is selected. Once it has been selected, its actual size is displayed.
- The required disk space displayed by the dialog includes the size of the files that must be installed to enable maintenance setups and uninstallation. Even if all application components are deselected, the size of these files is still displayed.
- If your setup does not use a setup type dialog, you *must* call `FeatureSetupTypeSet` to specify a setup type that has been defined in the IDE's Setup Types view before calling `SdFeatureMult`.
- `SdFeatureMult` operates on the current media, which is specified by the system variable `MEDIA`. During setup initialization, the installation assigns to `MEDIA` a media name that is associated with your file media library (`Data1.cab`).

#### Task

#### To display script-created features:

1. Save the current value of `MEDIA` in a string variable, for example, `szSaveMEDIAValue`.
  2. Assign to `MEDIA` the name of the script-created component set.
  3. Call `SdFeatureMult` to get end-user selections.
  4. Assign to `MEDIA` the value that you saved in step 1. You must do this before calling `FeatureTransferData`.
- If necessary, feature names are truncated to allow the display of the largest possible feature size. The space required to display the size depends on the maximum feature size (2 GB), the feature size options currently in use, and the font used to display feature information in the dialog. Feature size options are set with the `DialogSetInfo` function.

When the space required to display the maximum possible size has been determined, all feature names are truncated automatically, if necessary, to fit the remaining space. The name of a feature that requires less space to display its size (or that is not selected) may still be truncated under this method. To maximize performance and ensure that feature names appear complete, make feature names or display names smaller than the space available in the dialog.

- The Select Subfeatures dialog cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## SdFeatureMult Example

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdFeatureMult function.
 *
 * This example script displays a dialog that lets the user
 * select features and subfeatures, view feature descriptions,
 * and see the amount of space required for the selected features
 * and the space available on the destination folder.
 *
 * Comments: To run this example script, create a project (or
 *           insert into a project) with several features
 *           and/or subfeatures with components containing
 *           files.
 *
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, svDir;
begin

    svDir  = TARGETDIR;
    szTitle = "Select Features";
    szMsg   = "Select the features you want to install on your computer.";

    // Display all top-level features available.
    SdFeatureMult (szTitle, szMsg, svDir, "");

end;

```

## SdFeatureTree

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFeatureTree** function displays a dialog that contains the following:

- A tree control in which end users can select the features they want on their system and clear the features they do not want on their system.
- A description of the selected feature—the text in the feature's Description property.
- The drive space required to perform the file operations selected in the tree control, and the space available on the drive of the path specified by szDir. The calculation of required drive space takes into account the cluster size on the szDir drive.

## Syntax

```
SdFeatureTree ( szTitle, szMsg, szDir, szFeatures, nLevel );
```

## Parameters

**Table 35** • SdFeatureTree Parameters

| Parameter         | Description                                                                                                                                                                                                                                                               |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title ("Select Features"), pass a null string ("" ) in this parameter.                                                                                                                                          |
| <b>szMsg</b>      | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("" ) in this parameter.                                                                                                                          |
| <b>szDir</b>      | Specifies the path that is used in calculating required and available drive space. The script variable TARGETDIR should always be specified for this parameter.                                                                                                           |
| <b>szFeatures</b> | Specifies the name of the feature whose subfeatures are displayed. To display all top-level features, pass a null string ("" ) in this parameter. To learn how to refer to top-level features and subfeatures, see Specifying Features and Subfeatures in Function Calls. |
| <b>nLevel</b>     | Specifies how many levels of features and subfeatures are open in the tree control when the dialog is first displayed. (For example, an nLevel of 2 causes third- and lower-level subfeatures to be closed in the tree control when the dialog is first displayed.)       |

## Return Values

**Table 36** • SdFeatureTree Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- The required disk space displayed by the dialog includes the size of the files that must be installed to enable maintenance installations and uninstallation. Even if all application features are deselected, the size of these files is still displayed.

- **SdFeatureTree** operates on the current media, which is specified by the system variable MEDIA. During setup initialization, the installation assigns to MEDIA a media name that is associated with your file media library (Data1.cab).

**Task****To display script-created features:**

1. Save the current value of MEDIA in a string variable, for example, szSaveMEDIAValue.
2. Assign to MEDIA the name of the script-created component set.
3. Call **SdFeatureTree** to get end-user selections.
4. Assign to MEDIA the value that you saved in step 1. You must do this before calling **FeatureTransferData**.

## SdFeatureTree Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SdFeatureTree function.
*
* This example script displays a dialog that lets the user
* select features and subfeatures, view feature descriptions,
* and see the amount of space required for the selected features
* and the space available on the destination folder.
*
* Comments: To run this example script, create a project (or
*           insert into a project) with several features
*           and/or subfeatures with components containing
*           files.
*
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, svDir;
begin

    svDir  = TARGETDIR;
    szTitle = "Select Features";
    szMsg  = "Select the features you want to install on your computer.";

    // Display all top-level features available, with third- and
    // lower-level subfeatures to be closed in the tree control
    // when the dialog is first displayed.
```

```
SdFeatureTree (szTitle, szMsg, svDir, "", 2);

end;
```

## SdFilesInUse

**Project** - The InstallScript MSI project type support the **SdFilesInUse** function.

The **SdFilesInUse** dialog can also be called manually in InstallScript projects, in InstallScript MSI projects, and Basic MSI projects that have InstallScript custom actions; however, the installation must provide the list of applications that are locking files through the `nvlistApps` parameter, and it must handle the return value appropriately.

The **SdFilesInUse** function displays a dialog that includes a list box containing a list of the applications that are open and are locking files.

Typically, the `OnFilesInUse` event handler displays this dialog in an InstallScript MSI installation as a response to an `INSTALLMESSAGE_FILESINUSE` message sent by the Windows Installer. When this occurs, the Windows Installer provides to the installation the list of applications that are locking files. The list of applications are passed through the `szMessage` parameter to the `OnFilesInUse` event. The event passes this information to the **SdFilesInUse** function through the `szMessage` parameter. The event then passes the return value from the function as the return value of the event, which causes the Windows Installer to act appropriately.

### Syntax

```
SdFilesInUse ( byval string szTitle, byval string szMsg, byval string szFilesInUse, byref LIST
               nvlistApps );
```

## Parameters

**Table 37** ▪ SdFilesInUse Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>      | Specifies the title of the dialog. To display the default title (Files in Use), pass a null string ("" ) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>szMsg</b>        | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("" ) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szFilesInUse</b> | <p>When <b>SdFilesInUse</b> is called by the OnFilesInUse event handler in an InstallScript MSI installation, this parameter specifies the list of applications that the Windows Installer found to be locking files. The function parses this string in order to display the list of applications in the dialog's list box.</p> <p>If you manually call <b>SdFilesInUse</b>, pass an empty string ("" ) in this parameter. Note that if nvlistApps is a valid string list, this parameter is ignored.</p>                                                                                                                                                                                                              |
| <b>nvlistApps</b>   | <p>When <b>SdFilesInUse</b> is called by the OnFilesInUse event handler in an InstallScript MSI installation, this parameter is specified as an uninitialized list variable—that is, a variable with a value of 0.</p> <p>If you manually call <b>SdFilesInUse</b>, specify a string list of applications that are locking files and that should be displayed in the dialog. Each string in the list indicates one application. (Use the <b>ListCreate</b> function and associated list functions to create and initialize the string list.)</p> <div data-bbox="631 1123 669 1169" data-label="Image"> </div> <p><b>Note</b> ▪ You must provide a variable for this parameter; you cannot specify a literal value.</p> |

## Return Values

**Table 38** ▪ SdFilesInUse Return Values

| Return Value        | Description                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IDRETRY (4)</b>  | <p>Indicates that the end user clicked the Retry button.</p> <p>If you manually call <b>SdFilesInUse</b>, you should handle this return value by rechecking locked files and redisplaying the dialog as needed. When <b>SdFilesInUse</b> is called by the OnFilesInUse event handler, this value is returned by the event handler, and this is handled by the Windows Installer.</p> |
| <b>IDIGNORE (5)</b> | Indicates that the end user clicked the Ignore button.                                                                                                                                                                                                                                                                                                                               |

**Table 38** ▪ SdFilesInUse Return Values (cont.)

| Return Value    | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IDCANCEL</b> | Indicates that the end user clicked the Exit button.                                                                                                                                                                                                                                                                                                                                             |
|                 |  <p><b>Note</b> ▪ Note that unlike other script dialogs, this dialog does not call the <i>OnCanceling</i> event handler when the user clicks the Exit button. Therefore, if you are calling this function manually, you must handle this return value manually in order to display the Cancel Setup dialog.</p> |

## SdFilesInUse Example

**Project** ▪ The InstallScript MSI project type support the **SdFilesInUse** function.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SdFilesInUse function. SdFilesInUse displays
* a list box dialog that lists applications that are locking
* files.
*
* Keep displaying SdFilesInUse if Notepad.exe is running
* and user clicks Retry.
*
\*-----*/

#include "ifx.h"

function OnFirstUIBefore( )
    // ...other variables...
    LIST listID;
    NUMBER nReturn;
begin

    // ...display other dialogs...

    // display file-locked dialog only if Notepad.exe running
    if (Is(FILE_LOCKED, WINDIR ^ "Notepad.exe")) then
        // create a string list
        listID = ListCreate(STRINGLIST);

        // if an error occurred, report it; then terminate.
        if (listID = LIST_NULL) then
            MessageBox("Unable to create list.", SEVERE);
            abort;
        endif;
    endif;

```

```

ListAddString(listID, "Notepad.exe", AFTER);

AskAgain:

// display the Files in Use dialog.
nReturn = SdFilesInUse("", "The following applications are currently locking files.", "", listID);

// if user clicks RETRY, show locked-file dialog again;
// otherwise, let the file-transfer process handle it, which might require a reboot
if (nReturn = IDRETRY) then
    if (Is(FILE_LOCKED, WINDIR ^ "Notepad.exe")) then
        goto AskAgain;
    endif;
endif;

// remove the list from memory
ListDestroy(listID);
endif;

end;

```

## SdFinish

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFinish** function displays a dialog to inform the end user that the installation is complete and to provide information or options. The SdFinish dialog displays up to two messages and two check box selection options. For example, you could offer the end user the option of either viewing a README file or launching the application.

To insert the product name into the messages and check box descriptions, use the place holder %P in the strings passed in szMsg1, szMsg2, szOpt1, and szOpt2.

**Note** ▪ SdFinish has no option to terminate the setup and reboot the end user's computer. When SdFinish returns, the setup continues to execute. To provide the end user with the option to reboot, call SdFinishReboot instead.

### Syntax

```
SdFinish ( szTitle, szMsg1, szMsg2, szOpt1, szOpt2, bvOpt1, bvOpt2 );
```

## Parameters

**Table 39** ▪ SdFinish Parameters

| Parameter      | Description                                                                                                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of the dialog. To display the default title ("Setup Complete"), pass a null string ("") in this parameter.                                                                      |
| <b>szMsg1</b>  | Specifies the message to display at the top of the dialog. To display the default instructions, which inform the user that the installation is complete, pass a null string ("") in this parameter. |
| <b>szMsg2</b>  | Specifies the message to display at the bottom of the dialog. To display the default instructions ("Click Finish to complete Setup"), pass a null string ("") in this parameter.                    |
| <b>szOpt1</b>  | Specifies the text to display beside the first check box. Pass a null string ("") in this parameter to hide the check box.                                                                          |
| <b>szOpt2</b>  | Specifies the text to display beside the second check box. Pass a null string ("") in this parameter to hide the check box.                                                                         |
| <b>bvOpt1</b>  | Returns the selection state (TRUE or FALSE) of the first check box.                                                                                                                                 |
| <b>bvOpt2</b>  | Returns the selection state (TRUE or FALSE) of the second check box.                                                                                                                                |

## Return Values

**Table 40** ▪ SdFinish Return Values

| Return Value    | Description                                   |
|-----------------|-----------------------------------------------|
| <b>NEXT (1)</b> | Indicates that the Finish button was clicked. |

**Note** ▪ Because SdFinish announces the end of the installation, the Back button is disabled.

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdFinish Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the function SdFinish.
 *
 * Note: Before running this script, set the preprocessor
 *       constants so that they reference the fully-qualified
 *       names of the Windows Notepad executable and a valid
 *       text file in the Support Files/Billboards view.
 *
\*-----*/

//Assign the name of a text file to READMEFILE
#define NOTEPAD WINDIR ^ "Notepad.exe"
#define READMEFILE SUPPORTDIR ^ "ReadMe.txt"

#include "Ifx.h"

function OnBegin()
    STRING    szProductName, szTitle;
    STRING    szMsg1, szMsg2, szOpt1, szOpt2;
    BOOL      bvOpt1, bvOpt2;
    NUMBER    nReturn;
begin

    // Set the product name to substitute for the %P place holder.
    szProductName = "My Application";
    SdProductName (szProductName);

    // Setup parameters that will be passed to SdFinish.
    szTitle = "SdFinish Example";
    szMsg1 = "%P Setup is almost complete.\n" +
        "Choose the options you want below.";
    szMsg2 = "Click Finish to complete %P Setup.";
    szOpt1 = "I would like to view the README file.";
    szOpt2 = "I would like to launch %P.";

    // Display the SdFinish dialog.
    SdFinish (szTitle, szMsg1, szMsg2, szOpt1, szOpt2, bvOpt1, bvOpt2);

    if (bvOpt1) then
        // Display the read me file.
        LaunchAppAndWait (NOTEPAD, READMEFILE, WAIT);
    endif;

    if (bvOpt2) then
        // Because this example does not actually install an
        // application, a message box is displayed in place of
        // the call to LaunchApp that would normally be made here,
        // for example:
        // LaunchApp (TARGETDIR ^ "MyApp.exe","");
    endif;
endfunction

```

```

        SprintfBox (INFORMATION, szTitle, "Launch %s here.", szProductName);
    endif;

end;

```

## SdFinishEx

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFinishEx** function calls either SdFinish or SdFinishReboot to display a dialog that informs the end user that the installation is complete and provides information or options. If the system variable BATCH\_INSTALL is equal to FALSE (indicating that no locked files were encountered during the setup), SdFinishEx calls SdFinish to display the dialog. If BATCH\_INSTALL is equal to a non-zero value, SdFinishEx calls SdFinishReboot to display the dialog.

To insert the product name into the messages and check box descriptions, use the place holder %P in the strings passed in szMsg1, szMsg2, szOpt1, and szOpt2.

### Syntax

```
SdFinishEx (szTitle, szMsg1, szMsg2, szOpt1, szOpt2, bvOpt1, bvOpt2);
```

### Parameters

The parameters are the same as those of SdFinish. If BATCH\_INSTALL is equal to TRUE, these parameters are ignored and SdFinishReboot("", "", SYS\_BOOTMACHINE, "", 0) is called.

### Return Values

**Table 41** - SdFinishEx Return Values

| Return Value | Description                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that SdFinish was called.                                                                        |
| NEXT (1)     | Indicates that SdFinishReboot was called and the user chose not to reboot the computer.                    |
| < 0          | Indicates that SdFinishReboot was called and the user chose to reboot the computer, but the reboot failed. |

### Additional Information

To display non-default text in the SdFinishReboot dialog, do not call SdFinishEx. Instead, use code like the following:

```

if (!BATCH_INSTALL) then
    SdFinish( szTitle, szMsg1, szMsg2,

```

```

        szOption1, szOption2, bOpt1, bOpt2 );
else
    SdFinishReboot( szRebootTitle, szRebootMsg1,
        SYS_BOOTMACHINE, szRebootMsg2, 0 );
endif;

```

## SdFinishEx Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the function SdFinishEx.
 *
 * The SdFinishEx function calls either SdFinish or SdFinishReboot
 * to display a dialog informing the end user that the
 * installation is complete and giving the user information or
 * options. If the system variable BATCH_INSTALL is equal to
 * FALSE (0), indicating that no locked files were encountered
 * during the setup, SdFinishEx calls SdFinish to display the
 * dialog. If BATCH_INSTALL is equal to a non-zero value,
 * SdFinishEx calls SdFinishReboot to display the dialog.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg1, szMsg2, szOption1, szOption2;
    NUMBER bOpt1, bOpt2;
begin

    bOpt1  = FALSE;
    bOpt2  = FALSE;
    szMsg1 = SdLoadString(IFX_SDFINISH_MSG1);
    SdFinishEx(szTitle, szMsg1, szMsg2, szOption1, szOption2, bOpt1, bOpt2);
end;

```

## SdFinishReboot

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFinishReboot** function at the end of your installation announces that the installation is complete and gives the end user the option to restart the system. Restarting the system allows changes to Autoexec.bat, Config.sys, and some .ini files to take effect.

The **SdFinishReboot** dialog displays up to two messages in static text fields. Set the value of these fields with the parameters szMsg1 and szMsg2. To insert the product name into the messages, use the place holder %P in the strings passed in szMsg1 and szMsg2.

## Syntax

```
SdFinishReboot ( szTitle, szMsg1, nDefOption, szMsg2, nReserved );
```

## Parameters

**Table 42** ▪ SdFinishReboot Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title (“Setup Complete”), pass a null string (“”) in this parameter.                                                                                                                                                                  |
| <b>szMsg1</b>     | Specifies the text to display at the top of the dialog, informing the user about the end of the installation. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                   |
| <b>nDefOption</b> | Specifies a default radio button option selection. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>SYS_BOOTMACHINE</b>—Reboot the computer when the setup is finished.</li> <li>● <b>0</b>—Do not reboot the computer.</li> </ul> |
| <b>szMsg2</b>     | Specifies the text to display at the bottom of the dialog, giving the user information about what to do. To display the default instructions, pass a null string (“”).                                                                                                                          |
| <b>nReserved</b>  | Pass zero in this parameter. No other value is allowed.                                                                                                                                                                                                                                         |

## Return Values

**Table 43** ▪ SdFinishReboot Return Values

| Return Value       | Description                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>WILL_REBOOT</b> | Indicates that the user chose to reboot the system.                                                             |
| <b>NEXT (1)</b>    | Indicates that the user chose not to reboot the system or restart Windows.                                      |
| <b>&lt; 0</b>      | Indicates that the user chose to either reboot the system or restart Windows, but the reboot or restart failed. |

**Note** ▪ Because **SdFinishReboot** announces the end of the installation, the Back button is disabled.

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- The installation makes every attempt *not* to reboot the computer when other instances of the installation are running. Because of this, you must ensure that all other instances of the installation are shut down before allowing **SdFinishReboot** to restart Windows or the system. Additionally, your message to the end user should request that if they plan to restart the system later, they should ensure that all other applications are shut down first.

- The installation automatically ensures that locked .dll and .exe files are updated the next time that the system starts.

## SdFinishReboot Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdFinishReboot dialog.
 *
 * Warning: If you select the reboot option, your computer will
 *          reboot. Be sure you do not have any unsaved files
 *          open when you select this option.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg1, szMsg2;
    NUMBER nDefOption, nReserved;
begin

    // Set up variables to pass as parameters to SdFinishReboot.
    szTitle   = "SdFinishReboot Example";
    szMsg1    = "Setup has completed installing %P.";

    // nDefOption - Specifies a default radio button option selection.
    // SYS_BOOTMACHINE - Reboot the computer when the setup is finished.
    // 0 - Do not reboot the computer.
    nDefOption = 0;
    szMsg2     = "Click Finish to exit %P setup.";
    nReserved = 0;

    // Display the SdFinishReboot dialog.
    if (SdFinishReboot (szTitle, szMsg1, nOption, szMsg2, nReserved) < 0) then
        // Indicates that the user chose to either reboot the system
        // or restart Windows, but the reboot or restart failed.
        MessageBox ("SdFinishReboot failed.", SEVERE);
    endif;

end;
```

# SdFinishUpdate

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFinishUpdateEx** function supersedes the **SdFinishUpdate** function. **SdFinishUpdate** calls the following:

```
SdFinishUpdateEx( szTitle, szMsg1, szMsg2, "", "", bDefOption );
```

The **SdFinishUpdate** function at the end of your installation displays a dialog that indicates that the installation is complete. The dialog includes the option to check for application updates.

**Note** ▪ **SdFinishUpdate** does not check for updates; to check for updates, add FlexNet Connect API calls in your *InstallScript* code. For more information, see the *FlexNet Connect SDK documentation*.

## Syntax

```
SdFinishUpdate ( szTitle, szMsg1, szMsg2, bDefOption );
```

# SdFinishUpdateEx

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFinishUpdateEx** function at the end of your installation displays a dialog that indicates that the installation is complete. The dialog includes the option to check for application updates.

**Note** ▪ **SdFinishUpdateEx** does not check for updates; to check for updates, add FlexNet Connect API calls in your *InstallScript* code. For more information, see the *FlexNet Connect SDK documentation*.

## Syntax

```
SdFinishUpdateEx ( szTitle, szMsg1, szMsg2, szOpt1, szOpt2, bDefOption );
```

## Parameters

**Table 44** ▪ SdFinishUpdateEx Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title ("Setup Complete"), pass a null string ("") in this parameter.                                                                                                                                                                                                              |
| <b>szMsg1</b>     | Specifies the text to display at the top of the dialog, informing the user about the end of the installation. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                               |
| <b>szMsg2</b>     | Specifies the text to display at the bottom of the dialog, providing information to the end user about what to do next. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                     |
| <b>szOpt1</b>     | Specifies the text to display beside the first radio button. To display the default instructions ("Yes, check for program updates. (Recommended)\nPlease ensure that you're connected to the Internet before you proceed."), pass a null string ("") in this parameter.                                                                     |
| <b>szOpt2</b>     | Specifies the text to display beside the second radio button. To display the default instructions ("No, skip this step."), pass a null string ("") in this parameter.                                                                                                                                                                       |
| <b>bDefOption</b> | Specifies the option button that is selected by default. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Specifies the first option button as the default selection.</li> <li>• <b>FALSE</b>—Specifies the second option button as the default selection.</li> </ul> |

## Return Values

**Table 45** ▪ SdFinishUpdateEx Return Values

| Return Value | Description                                                                    |
|--------------|--------------------------------------------------------------------------------|
| <b>TRUE</b>  | Indicates that the <b>Check for program updates</b> option button is selected. |
| <b>FALSE</b> | Indicates that the <b>Skip this step</b> option is selected.                   |

**Note** ▪ Because SdFinishUpdateEx announces the end of the installation, the Back button is disabled.

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

# SdFinishUpdateReboot

---

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdFinishUpdateReboot** function at the end of your installation displays a dialog that indicates that the installation is complete. The dialog gives the end user the option to restart the system and to check for application updates. Restarting the system enables changes to Autoexec.bat, Config.sys, and some .ini files to take effect.

---

**Note** ▪ **SdFinishUpdateReboot** does not check for updates; to check for updates, add FlexNet Connect API calls in your InstallScript code. For more information, see the FlexNet Connect SDK documentation.

## Syntax

```
SdFinishUpdateReboot ( szTitle, szMsg1, nDefOption, szMsg2, nChkUpdate, nReserved );
```

## Parameters

**Table 46** ▪ SdFinishUpdateReboot Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>     | Specifies the title of the dialog. To display the default title (“Setup Complete”), pass a null string (“”) in this parameter.                                                                                                                                                           |
| <b>szMsg1</b>      | Specifies the text to display at the top of the dialog, informing the end user about the end of the installation. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                        |
| <b>nDefOption</b>  | Specifies a default radio button selection. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>SYS_BOOTMACHINE</b>—Reboot the computer when the setup is finished.</li> <li>● <b>0</b>—Do not reboot the computer.</li> </ul> |
| <b>szMsg2</b>      | Specifies the text to display at the bottom of the dialog, giving the end user information about what to do. To display the default instructions, pass a null string (“”).                                                                                                               |
| <b>nvChkUpdate</b> | Returns the state of the FlexNet Connect check box: <ul style="list-style-type: none"> <li>● <b>0</b>—Check box is not selected. Do not check for application updates.</li> <li>● <b>Other than 0</b>—Check box is selected. Check for application updates.</li> </ul>                   |
| <b>nReserved</b>   | Pass zero in this parameter. No other value is allowed.                                                                                                                                                                                                                                  |

## Return Values

**Table 47** ▪ SdFinishUpdateReboot Return Values

| Return Value       | Description                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>WILL_REBOOT</b> | Indicates that the end user chose to reboot the system.                                                             |
| <b>NEXT (1)</b>    | Indicates that the end user chose not to reboot the system or restart Windows.                                      |
| <b>&lt; 0</b>      | Indicates that the end user chose to either reboot the system or restart Windows, but the reboot or restart failed. |

**Note** ▪ Because *SdFinishUpdateReboot* announces the end of the installation, the *Back* button is disabled.

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdFinishUpdateReboot Example

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdFinishUpdateReboot dialog.
 *
 * This dialog is used at the end of an installation to announce
 * that the installation is complete and gives the user the option
 * to restart the system and to check for application updates.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes
#include "ifx.h"

export prototype ExFn_SdFinishUpdateReboot(HWND);

function ExFn_SdFinishUpdateReboot(hMSI)
    STRING szTitle, szMsg1, szMsg2;
    NUMBER nDefOption, nChkUpdate, nReserved;
begin

    szTitle = "SdFinishUpdateReboot Example";
    szMsg1  = "";
    szMsg2  = "";

    // nDefOption - Specifies the option button selected by default.
    // 1 - Yes, check for program updates
    // 0 - No, skip this step
    nDefOption = 1;

    // nChkUpdate - Specifies the default state of the FlexNet Connect check box.
    // nChkUpdate - Returns the state of the FlexNet Connect check box.
    // 0 - Check box is not selected. Do not check for application updates.
    // Other than 0 - Check box is selected. Check for application updates.
    nChkUpdate = 1;
    nReserved = 0;
    SdFinishUpdateReboot ( szTitle, szMsg1, nDefOption, szMsg2, nChkUpdate, nReserved );

end;
```

# SdGeneralInit

The **SdGeneralInit** function provides standard dialog initialization, including setting the enable or disable state of the Next, Back, and Cancel buttons. This function also replaces all %P, %VS, and %VI instances with IFX\_PRODUCT\_DISPLAY\_NAME, IFX\_PRODUCT\_DISPLAY\_VERSION, and IFX\_INSTALLED\_DISPLAY\_VERSION on static controls with control IDs 700 through 724, and 202.

## Syntax

```
SdGeneralInit (szDialog, hwndDlg, nUnused, szUnused);
```

## Parameters

**Table 48** • SdGeneralInit Parameters

| Parameter       | Description                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------|
| <b>szDialog</b> | Name of the dialog created with <a href="#">EzDefineDialog</a> or <a href="#">DefineDialog</a> . |
| <b>hwndDlg</b>  | Handle to the current dialog. This is obtained by calling <a href="#">CmdGetHwndDlg</a> .        |
| <b>nUnused</b>  | Unused parameter; pass 0.                                                                        |
| <b>szUnused</b> | Unused parameter; pass an empty string ("").                                                     |

## Return Values

None.

## SdGeneralInit Example

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SdGeneralInit, which is used to initialize
* a dialog that is created with the EzDefineDialog function.
*
* This script opens a simple custom dialog that displays
* a bitmap. The dialog can be closed with any of three
* buttons: Back, Next, or Cancel.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdBitmap. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
*
* In order to use this custom dialog, the script first defines
* it by calling EzDefineDialog. It then displays the dialog
* and gets dialog events by calling WaitOnDialog. When an
```

```

* event ends dialog processing, EndDialog is called to close
* the dialog. Then the dialog is released from memory by
* a call to ReleaseDialog.
*
\*-----*/

// Dialog and control IDs.
#define RES_DIALOG_ID      12027  // ID of dialog itself
#define RES_PBUT_NEXT      1      // ID of Next button
#define RES_PBUT_CANCEL    9      // ID of Cancel button
#define RES_PBUT_BACK      12     // ID of Back button

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_EzDefineDialog(HWND);

function ExFn_EzDefineDialog(hMSI)
    STRING  szDialogName, szDLLName, szDialog;

end;

```

## SdInit

The **SdInit** function prepares an installation for Sd dialog function calls by loading required resource strings, restoring the installation's window if it is minimized, and specifying Windows 95-style check boxes in Sd dialogs.

---

**Note** ▪ This function is called automatically by each Sd function. It is unnecessary to call SdInit explicitly unless your script calls DialogSetInfo before calling any of the Sd dialog functions. In that case, your script must call SdInit before it calls DialogSetInfo—otherwise the call to DialogSetInfo has no effect.

### Syntax

SdInit ( );

### Parameters

This function takes no parameters.

## Return Values

**Table 49** ▪ SdInit Return Values

| Return Value | Description                                                                         |
|--------------|-------------------------------------------------------------------------------------|
| 0            | Indicates that the setup was initialized for Sd dialog function calls.              |
| 1            | Indicates that the setup has already been initialized for Sd dialog function calls. |

## SdInit Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdInit function.
 *
 * Note that SdInit is called automatically by each Sd function.
 * It is unnecessary to call SdInit explicitly unless your script
 * calls DialogSetInfo before calling any of the Sd dialog functions.
 * In that case, your script must call SdInit before it calls
 * DialogSetInfo—otherwise the call to DialogSetInfo has no effect.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szInfoString;
begin

    // Initialize setup for calls to Sd dialog functions.
    SdInit ();

    // Set check box style for feature selection.
    DialogSetInfo ( DLG_INFO_CHECKSELECTION, szInfoString, CHECKBOX );

    // Get feature selections.
    SdFeatureDialog2 ( "", "", TARGETDIR, "" );

end;

```

## SdLicense

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdLicenseEx** function supersedes the **SdLicense** function.

The **SdLicense** function displays a dialog that contains a license agreement in a multi-line edit field. The license agreement is stored in a text file identified in the parameter `szLicenseFile`.

The end user can scroll up and down to read the agreement. The end user must choose either the Yes, No, or—if enabled—Back button. Because this is usually the first dialog that you would display, you might want to disable the Back button. If the user selects Yes, the installation continues. If the user selects No, the installation displays the ExitSetup dialog.

## Syntax

```
SdLicense ( szTitle, szMsg, szQuestion, szLicenseFile );
```

## Parameters

**Table 50** ▪ SdLicense Parameters

| Parameter                                           | Description                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>                                      | Specify the title of the dialog. To display the default title ("Software License Agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                          |
| <b>szMsg</b>                                        | Specify the message to display in the static text field above the multi-line edit field. To display the default instructions, pass a null string ("") in this parameter.                                                                                                                                                                                                          |
| <b>szQuestion</b>                                   | Specify the text to display in the static text field below the multi-line edit field. You would likely place a question here, to which the user should respond by selecting either Yes and No. To display the default instructions, pass a null string ("") in this parameter.                                                                                                    |
| <b>szLicenseFile</b>                                | Specify the name of the ANSI text file that contains the license agreement. This file must be added to the appropriate language folder in the Support Files/Billboards view. You can also specify szLicenseFile by entering the fully qualified name, in quotation marks, or a UNC path.<br><br> |
| <b>Note</b> ▪ This file must be a text file (.txt). |                                                                                                                                                                                                                                                                                                                                                                                   |

## Return Values

**Table 51** ▪ SdLicense Return Values

| Return Value     | Description                                       |
|------------------|---------------------------------------------------|
| <b>YES (1)</b>   | The end user selected the Yes button.             |
| <b>BACK (12)</b> | Indicates that the user selected the Back button. |

**Note** ▪ This function cannot return NO because if the end user clicks the No button, the ExitSetup dialog is displayed.

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdLicense Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdLicense function.
 *
 * This script calls SdLicense to display a license agreement
 * and prompt the user to accept or reject that agreement.
 *
 * Note: The license agreement is read from a text file that
 *       is stored at the location specified by the constant
 *       LICENSE_PATH. Before running this script, set that
 *       constant so that it references an existing text file
 *       in the Support Files/Billboards view.
 *
 \*-----*/

#define LICENSE_PATH SUPPORTDIR ^ "License.txt"
#define TITLE "SdLicense Example"

#include "Ifx.h"

function OnBegin()
    STRING szMsg, szQuestion;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set up the variables to pass as parameters to SdLicense.
    szMsg      = "Please read the following license agreement. Use " +
                "the scroll bar to view\nthe rest of this agreement.";
    szQuestion = "Select Yes to accept the agreement.\n" +
                "Select No to cancel the setup.";

    // Display the SdLicense dialog.
    if (SdLicense (TITLE, szMsg, szQuestion, LICENSE_PATH) = YES) then
        MessageBox ("Continue with the installation.", INFORMATION);
    endif;

end;

```

## SdLicense2

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The [SdLicense2Ex](#) function supersedes the **SdLicense2** function.

The **SdLicense2** function displays a dialog that contains a license agreement in a multi-line edit field. The license agreement is stored in a text file identified in the parameter `szLicenseFile`.

The end user can scroll up and down to read the agreement. The end user must select the upper option button for the Next button to become enabled, which allows the installation to continue. Because this is usually the first dialog that you would display, you might want to disable the Back button.

## Syntax

```
SdLicense2 ( szTitle, szOpt1, szOpt2, szLicenseFile, bLicenseAccepted );
```

## Parameters

**Table 52** ▪ SdLicense2 Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>          | Specify the title of the dialog. To display the default title ("License Agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                              |
| <b>szOpt1</b>           | Specify the text to display in the static text field next to the upper option button. To display the default text ("I accept the terms of the license agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                |
| <b>szOpt2</b>           | Specify the text to display in the static text field next to the lower option button. To display the default text ("I do not accept the terms of the license agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                         |
| <b>szLicenseFile</b>    | <p>Specify the name of the ANSI text file that contains the license agreement. This file must be added to the appropriate language folder in the Support Files/Billboards view. You can also specify szLicenseFile by entering the fully qualified name, in quotation marks, or a UNC path.</p>  <p><b>Note</b> ▪ This file must be a text file (.txt).</p> |
| <b>bLicenseAccepted</b> | <p>Specify the option button that is selected by default. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Specifies the upper option button as the default selection.</li> <li>• <b>FALSE</b>—Specifies the lower option button as the default selection.</li> </ul>                                                                                              |

## Return Values

**Table 53** ▪ SdLicense2 Return Values

| Return Value              | Description                                                        |
|---------------------------|--------------------------------------------------------------------|
| <b>NEXT</b>               | The end user selected the upper option button and the Next button. |
| <b>BACK</b>               | The end user selected the Back button.                             |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.                                 |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdLicense2 Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdLicense2 function.
 *
 * This script calls SdLicense2 to display a license agreement
 * and prompt the user to accept or reject that agreement.
 *
 * Note: The license agreement is read from a text file that
 *       is stored at the location specified by the constant
 *       LICENSE_PATH. Before running this script, set that
 *       constant so that it references an existing text file
 *       on the target system.
 *
 \*-----*/

#define LICENSE_PATH "License.txt"
#define TITLE "SdLicense2 Example"

#include "ifx.h"

function OnBegin()
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Display the SdLicense2 dialog.
    if (SdLicense2 (TITLE, "", "", LICENSE_PATH, FALSE) = NEXT) then
        MessageBox ("Continue with the installation.", INFORMATION);
    endif;

end;
```

## SdLicense2Ex

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdLicense2Ex** function displays a dialog that contains a license agreement in a multi-line edit field. The license agreement is stored in a text file (.txt) or a rich text format file (.rtf) identified in the parameter `szLicenseFile`.

The end user can scroll up and down to read the agreement. The end user must select the upper option button for the Next button to become enabled, which allows the installation to continue. Because this is usually the first dialog that you would display, you might want to disable the Back button.

## Syntax

```
SdLicense2Ex (byval string szTitle, byval string szOpt1, byval string szOpt2, byval string  
             szLicenseFile, byval bool bLicenseAccepted, byval bool bRtf);
```

## Parameters

**Table 54** ▪ SdLicense2Ex Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>          | Specify the title of the dialog. To display the default title ("License Agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                   |
| <b>szOpt1</b>           | Specify the text to display in the static text field next to the upper option button. To display the default text ("I accept the terms of the license agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                     |
| <b>szOpt2</b>           | Specify the text to display in the static text field next to the lower option button. To display the default text ("I do not accept the terms of the license agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                              |
| <b>szLicenseFile</b>    | <p>Specify the name of the ANSI text file or .rtf file that contains the license agreement. This file must be added to the appropriate language folder in the Support Files/ Billboards view. You can also specify szLicenseFile by entering the fully qualified name, in quotation marks, or a UNC path.</p>  <p><b>Note</b> ▪ If you are using an .rtf file, the file size limit is 16 MB.</p> |
| <b>bLicenseAccepted</b> | <p>Specify the option button that is selected by default. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Specifies the upper option button as the default selection.</li> <li>• <b>FALSE</b>—Specifies the lower option button as the default selection.</li> </ul>                                                                                                                                   |
| <b>bRtf</b>             | <p>Indicate whether to use the dialog with the rich text edit control. Available options are:</p> <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Use the rich text edit control. If you select this option, the file that you specify for szLicenseFile must be an .rtf file.</li> <li>• <b>FALSE</b>—Use the standard edit control. If you select this option, the file that you specify for szLicenseFile must be a .txt file.</li> </ul>                                 |

## Return Values

**Table 55** ▪ SdLicense2Ex Return Values

| Return Value              | Description                                                        |
|---------------------------|--------------------------------------------------------------------|
| <b>NEXT</b>               | The end user selected the upper option button and the Next button. |
| <b>BACK</b>               | The end user selected the Back button.                             |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.                                 |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

# SdLicense2Rtf

---

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The [SdLicense2Ex](#) function supersedes the **SdLicense2Rtf** function.

The **SdLicense2Rtf** function displays a dialog that contains a license agreement in a multi-line edit field. The license agreement is stored in a text file or rich text format file (.rtf) file identified in the parameter `szLicenseFile`.

The user can scroll up and down to read the agreement, then must select the upper option button for the Next button to become enabled, which allows the setup to continue. Because this is usually the first dialog you would display, you might want to disable the Back button.

## Syntax

```
SdLicense2Rtf ( szTitle, szOpt1, szOpt2, szLicenseFile, bLicenseAccepted );
```

## Parameters

**Table 56** ▪ SdLicense2Rtf Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>          | Specify the title of the dialog. To display the default title ("License Agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                   |
| <b>szOpt1</b>           | Specify the text to display in the static text field next to the upper option button. To display the default text ("I accept the terms of the license agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                     |
| <b>szOpt2</b>           | Specify the text to display in the static text field next to the lower option button. To display the default text ("I do not accept the terms of the license agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                              |
| <b>szLicenseFile</b>    | <p>Specify the name of the .rtf file or ANSI text file that contains the license agreement. This file must be added to the appropriate language folder in the Support Files/ Billboards view. You can also specify szLicenseFile by entering the fully qualified name, in quotation marks, or a UNC path.</p>  <p><b>Note</b> ▪ If you are using an .rtf file, the file size limit is 16 MB.</p> |
| <b>bLicenseAccepted</b> | <p>Specifies the option button that is selected by default. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Specifies the upper option button as the default selection.</li> <li>• <b>FALSE</b>—Specifies the lower option button as the default selection.</li> </ul>                                                                                                                                 |

## Return Values

**Table 57** ▪ SdLicense2Rtf Return Values

| Return Value              | Description                                                        |
|---------------------------|--------------------------------------------------------------------|
| <b>NEXT</b>               | The end user selected the upper option button and the Next button. |
| <b>BACK</b>               | The end user selected the Back button.                             |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.                                 |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdLicense2Rtf Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdLicense2Rtf function.
 *
 * This script calls SdLicense2Rtf to display a license agreement
 * and prompt the user to accept or reject that agreement.
 *
 * Note: The license agreement is read from an RTF file that
 *       is stored at the location specified by the constant
 *       LICENSE_PATH. Before running this script, set that
 *       constant so that it references an existing RTF file
 *       on the target system.
 *
\*-----*/

#define LICENSE_PATH "License.rtf"
#define TITLE "SdLicense2Rtf Example"

#include "ifx.h"

function OnBegin()
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Display the SdLicense2Rtf dialog.
    if (SdLicense2Rtf (TITLE, "", "", LICENSE_PATH, FALSE) = NEXT) then
        MessageBox ("Continue with the installation.", INFORMATION);
    endif;

end;
```

## SdLicenseEx

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdLicenseEx** function displays a dialog that contains a license agreement in a multi-line edit field. The license agreement is stored in a text file (.txt) or a rich text format file (.rtf).

The end user can scroll up and down to read the agreement. The end user must choose either the Yes, No, or—if enabled—Back button. Because this is usually the first dialog that you would display, you might want to disable the Back button. If the user selects Yes, the installation continues. If the user selects No, the installation displays the ExitSetup dialog.

## Syntax

```
SdLicenseEx (byval string szTitle, byval string szMsg, byval string szQuestion, byval string  
            szLicenseFile, byval bool bRtf);
```

## Parameters

**Table 58** ▪ SdLicenseEx Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>       | Specify the title of the dialog. To display the default title ("Software License Agreement"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                   |
| <b>szMsg</b>         | Specify the message to display in the static text field above the multi-line edit field. To display the default instructions, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                   |
| <b>szQuestion</b>    | Specify the text to display in the static text field below the multi-line edit field. You would likely place a question here, to which the user should respond by selecting either Yes and No. To display the default instructions, pass a null string ("") in this parameter.                                                                                                                                                             |
| <b>szLicenseFile</b> | Specify the name of the ANSI text file or .rtf file that contains the license agreement. This file must be added to the appropriate language folder in the Support Files/Billboards view. You can also specify szLicenseFile by entering the fully qualified name, in quotation marks, or a UNC path.<br><br>                                             |
|                      | <b>Note</b> ▪ If you are using an .rtf file, the file size limit is 16 MB.                                                                                                                                                                                                                                                                                                                                                                 |
| <b>bRtf</b>          | Indicate whether to use the dialog with the rich text edit control. Available options are: <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Use the rich text edit control. If you select this option, the file that you specify for szLicenseFile must be an .rtf file.</li> <li>• <b>FALSE</b>—Use the standard edit control. If you select this option, the file that you specify for szLicenseFile must be a .txt file.</li> </ul> |

## Return Values

**Table 59** ▪ SdLicenseEx Return Values

| Return Value     | Description                            |
|------------------|----------------------------------------|
| <b>YES (1)</b>   | The end user selected the Yes button.  |
| <b>BACK (12)</b> | The end user selected the Back button. |

**Note** ▪ This function cannot return NO because if the end user clicks the No button, the ExitSetup dialog is displayed.

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

```
SdLicenseRtf ( szTitle, szMsg, szQuestion, szLicenseFile );
```

## Parameters

**Table 60** ▪ SdLicenseRtf Parameters

| Parameter                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>                                                             | Specify the title of the dialog. To display the default title (“Software License Agreement”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                        |
| <b>szMsg</b>                                                               | Specify the message to display in the static text field above the multi-line edit field. To display the default instructions, pass a null string (“”) in this parameter.                                                                                                                                                                                                                        |
| <b>szQuestion</b>                                                          | Specify the text to display in the static text field below the multi-line edit field. You would likely place a question here, to which the user should respond by selecting either Yes and No. To display the default instructions, pass a null string (“”) in this parameter.                                                                                                                  |
| <b>szLicenseFile</b>                                                       | Specify the name of the .rtf file or ANSI text file that contains the license agreement. This file must be added to the appropriate language folder in the Support Files/ Billboards view. You can also specify szLicenseFile by entering the fully qualified name, in quotation marks, or a UNC path.<br><br> |
| <b>Note</b> ▪ If you are using an .rtf file, the file size limit is 16 MB. |                                                                                                                                                                                                                                                                                                                                                                                                 |

## Return Values

**Table 61** ▪ SdLicenseRtf Return Values

| Return Value     | Description                            |
|------------------|----------------------------------------|
| <b>YES (1)</b>   | The end user selected the Yes button.  |
| <b>BACK (12)</b> | The end user selected the Back button. |

**Note** ▪ This function cannot return NO because if the end user clicks the No button, the ExitSetup dialog is displayed.

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdLicenseRtf Example

**Project** - This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdLicenseRtf function.
 *
 * This script calls SdLicenseRtf to display a license agreement
 * and prompt the user to accept or reject that agreement.
 *
 * Note: The license agreement is read from an RTF file that
 *       is stored at the location specified by the constant
 *       LICENSE_PATH. Before running this script, set that
 *       constant so that it references an existing RTF file
 *       in the Support Files/Billboards view.
 *
\*-----*/

#define LICENSE_PATH SUPPORTDIR ^ "License.rtf"
#define TITLE "SdLicenseRtf Example"

#include "Ifx.h"

function OnBegin()
    STRING szMsg, szQuestion;
    begin

        // Disable the Back button in setup dialogs.
        Disable (BACKBUTTON);

        // Set up the variables to pass as parameters to SdLicense.
        szMsg      = "Please read the following license agreement. Use " +
                    "the scroll bar to view\nthe rest of this agreement.";
        szQuestion = "Select Yes to accept the agreement.\n" +
                    "Select No to cancel the setup.";

        // Display the SdLicenseRtf dialog.
        if (SdLicenseRtf (TITLE, szMsg, szQuestion, LICENSE_PATH) = YES) then
            MessageBox ("Continue with the installation.", INFORMATION);
        endif;
    end;
end;
```

# SdLoadString

The **SdLoadString** function returns the string value associated with the specified resource ID. The InstallScript engine first looks for the resource in `_isuser.dll`, if that file exists. If the resource is not found, the InstallScript engine looks in `_isres.dll`.

## Syntax

```
SdLoadString (nID);
```

## Parameters

**Table 62** • SdLoadString Parameters

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nID</b> | Specifies the identifier of a string resource in <code>_isuser.dll</code> or <code>_isres.dll</code> . Some valid values of nID can be found in the <i>InstallShield Program Files Folder\Script\Ifx\Include</i> subfolder's <code>Ifx.h</code> file. The default <code>OnMaintUIBefore</code> event handler function code uses the following identifiers with their corresponding string values: <ul style="list-style-type: none"> <li><b>IFX_MAINTUI_MSG</b>—Do you want to completely remove the selected application and all of its components?</li> <li><b>IFX_ONMAINTUI_CAPTION</b>—Confirm Uninstall</li> </ul> |

## Return Values

**Table 63** • SdLoadString Return Values

| Return Value                   | Description                                                      |
|--------------------------------|------------------------------------------------------------------|
| <b>non-null string value</b>   | The string value successfully retrieved by <b>SdLoadString</b> . |
| <b>null string value ("" )</b> | Indicates that <b>SdLoadString</b> failed.                       |

## SdLoadString Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SdLoadString function.
*
* This script calls SdLoadString to get the string resource
```

```

* that is stored in _isres.dll with the ID IFX_MAINTUI_MSG.
* That string resource is then displayed in a message box.
*
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING svResource;
begin

    // Get the string resource.
    svResource = SdLoadString (IFX_MAINTUI_MSG);

    if (svResource = "") then
        // Report the error.
        MessageBox ("SdLoadString failed.", WARNING);
    else
        // Display the string resource.
        SprintfBox ( INFORMATION , "SdLoadString" ,
                    "Value of string resource %ld:\n%s" , IFX_MAINTUI_MSG,
                    svResource );
    endif;

end;

```

## SdLogonUserBrowse

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SdLogonUserBrowse** function displays a dialog that allows the end user to select a domain or server and a user name. This dialog is displayed when an end user clicks the Browse button on the **SdLogonUserInformation** dialog.

### Syntax

```
SdLogonUserBrowse();
```

## SdLogonUserCreateUser

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SdLogonUserCreateUser** function displays a dialog that allows the end user to enter new user information after the end user clicks the New User Information button on the **SdLogonUserInformation** dialog.

## Syntax

```
SdLogonUserCreateUser();
```

# SdLogonUserInformation

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdLogonUserInformation** function displays a dialog that prompts the end user for existing user account information or new user information if an account is to be created during the installation.

If the end user clicks the Browse button next to the User box, the **SdLogonUserBrowse** dialog is displayed.

## Syntax

```
SdLogonUserInformation (byval string szTitle, byval string szMsg, byref string szAssociatedAccountName,  
byref string szAssociatePassword);
```

## Parameters

**Table 64** ▪ SdLogonUserInfoParameters

| Parameter                      | Description                                                                                                    |
|--------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>                 | Specifies the title of the dialog. To display the default title, pass a null string ("" ) in this parameter.   |
| <b>szMsg</b>                   | Specifies the message in the dialog. To display the default title, pass a null string ("" ) in this parameter. |
| <b>szAssociatedAccountName</b> | Specifies the BYREF value that is the account name. Example: INSTALLSHIELD\John Smith                          |
| <b>szAssociatePassword</b>     | Specifies the BYREF value that is the password.                                                                |

## Return Values

**Table 65** ▪ SdLogonUserInfoReturn Values

| Return Value              | Description                                       |
|---------------------------|---------------------------------------------------|
| <b>NEXT</b>               | Indicates that the user selected the Next button  |
| <b>BACK</b>               | Indicates that the user selected the Back button. |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the dialog could not be displayed. |

# SdLogonUserListGroup

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdLogonUserListGroup** function displays a dialog that allows the end user to select a group from a specified server or domain and populate the Group field in the SdLogonUserCreateUser dialog.

## Syntax

```
SdLogonUserListGroup();
```

# SdLogonUserListServers

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdLogonUserListServers** function displays a dialog that allows the end user to browse for the domain or server with which the user account is associated.

### Syntax

```
SdLogonUserListServers();
```

## SdLogonUserListUsers

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdLogonUserListUsers** function displays a dialog that allows the end user to browse and select an existing user for a specified domain or server.

### Syntax

```
SdLogonUserListUsers();
```

## SdMakeName

The **SdMakeName** function creates a section name for a custom dialog. This section name is used in writing to and reading from an .iss file, which is used when running an InstallScript-based installation project's Setup.exe in silent mode.

### Syntax

```
SdMakeName ( svSection, szDlg, szUnused, nvDlgName );
```

## Parameters

**Table 66** ▪ SdMakeName Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svSection</b> | Specifies the section name (for example, "MyDlg-0"). InstallShield places a value into this variable using the variables szDlg and nvDlgName. This value is used by SilentReadData and SilentWriteData.                                                                                                                                                                                                                                                                                                                                      |
| <b>szDlg</b>     | Specifies the name of the custom dialog (for example, "MyDlg") for which to create a section name.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szUnused</b>  | This parameter is not used; pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>nvDlgName</b> | <p>Specifies the counter that records the number of times SdMakeName is called for the dialog named in szDlg. InstallShield automatically increments this counter.</p> <p>For sections to be properly named, you must use a unique variable name in this parameter for each different custom dialog. A simple way to do this is to use the dialog name in szDlg to name the variable. For example, when szDlg is "MyDlgOne," name the variable in this parameter nvMyDlgOne, and when szDlg is "MyDlgTwo," name the variable nvMyDlgTwo.</p> |

## Return Values

None.

## SdMakeName Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the functions SdMakeName, SilentReadData, and
* SilentWriteData.
*
* This example script shows how to handle a custom dialog
* in a silent installation. The resource .dll for the example
* custom dialog shown below should be stored in a compressed
* form under the Support Files/Billboards view of InstallShield.
*
* The example dialog was built from the custom dialog
* template provided with InstallShield.
*
* Dialog control IDs and other information are included in

```

```

* the Resource.h file (not shown). This file, which is included
* in the first line of the example, must be inserted in the
* InstallScript view of InstallShield.
*
* The example creates a text file called Cominit.txt. If the
* installation runs in silent mode, SilentReadData is called
* and the custom dialog control selections are read from
* the .iss file. The selections are then saved in the file
* Cominit.txt as a means of demonstrating that they were
* successfully read from the .iss file. If the installation
* runs in normal mode, the custom dialog is displayed
* and the selections are recorded in the .iss file and
* displayed in message boxes. The initial .ISS file text is
* shown after the example script.
*

## SdOptionsButtons

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SdOptionsButtons** function displays a dialog that contains from one to four push button controls that have bitmap images. A short text description is displayed next to each control.

**Important** ▪ Do not change the control identifiers of the push button controls on the **SdOptionsButtons** dialog, or set one of the push button controls as the default control. If you change the control identifiers or set one of the these controls as the default control of the dialog, the **SdOptionsButtons** dialog will not work as expected.

---

**Note** ▪ Although **SdOptionsButtons** can be used as a setup type dialog, the **SdSetupTypeEx** dialog is the recommended dialog for allowing the end user to select a setup type because it does not require any customization. If you call **SdOptionsButtons** to get the end user's setup type selection, you must then call **FeatureSetupTypeSet** to establish the selected setup type for your setup.

## Syntax

```
SdOptionsButtons (szTitle, szMsg, listButton, listDescription);
```

## Parameters

**Table 67** ▪ SdOptionsButtons Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>szTitle</b>    | Specifies the dialog title. To display the default title (“Select Features”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>szMsg</b>      | Specifies the message to display on the dialog. To display the default instructions for this dialog (“Please select the features that you want to install.”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>listButton</b> | <p>Specifies a string list that contains from one to four elements. Each element is a formatted string that specifies an image to be displayed on a button. One button is displayed for each string element in the list. The string list elements should have the following format:</p> <p><code>@@ResourceID;ScaleFactor</code></p> <p><i>ResourceID</i> indicates the resource identifier number that should be used to look up either a .png image (stored as resource type PNG) or a bitmap image (stored as resource type RT_BITMAP). <i>ScaleFactor</i> indicates the DPI scale percentage for which the image is intended.</p> <p>For example, the scale factor can be 100% (96 DPI), 125% (120 DPI), 150% (144 DPI), or 200% (192 DPI). If the scale factor that is specified for an image is 200, the image will be shrunk down for display on target systems that are running less than 200% DPI scaling. On a 200% target system, it will be displayed at 1:1. If the scale factor that is specified for the image is 100, the image will be scaled up for display on target systems that are running 200% DPI scaling.</p> |

**Table 67** ▪ SdOptionsButtons Parameters (cont.)

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listButton (cont.)</b> | <p>The previous format for identifying bitmap images (.bmp) still works, but it does not have support for scaling, or for .png images:</p> <pre>@BitmapResourceID;TransparentFlag;3-DFlag;&lt;unused&gt;;TransparentColorKey</pre> <p><i>BitmapResourceID</i> indicates the resource identifier number for the bitmap image. <i>TransparentFlag</i> is 1 (true) or 0 (false), indicating whether the color that is specified in the <i>TransparentColorKey</i> field will be transparent when the bitmap is displayed. <i>TransparentColorKey</i> specifies an RGB value that is a transparent color for the bitmap.</p> <p>InstallShield provides four default bitmaps in <i>_isres.dll</i> that can be used by this function. These bitmaps have IDs of 12001 through 12004 and correspond to the Typical, Portable, Compact, and Custom setup types in the example script. If you are using this dialog for another purpose or if you want to use setup types other than the types provided in <i>_isres.dll</i>, you must to add your own custom buttons to the <i>_isuser.dll</i> dialog template and then include the customized <i>_isuser.dll</i> with your installation.</p> <div data-bbox="630 909 672 953" data-label="Image"> </div> <p><b>Tip</b> ▪ To determine the bitmap IDs of bitmap controls created in the Dialog Editor, you need to build your project and open the .rc file to locate the bitmap IDs. The .rc file is located in your project folder (by default, <i>C:\InstallShield 2022 Projects\Your Project Name</i>). Adding additional bitmap controls may change the bitmap IDs. Because of this, you need to rebuild your project and open the .rc file again to find the updated bitmap IDs.</p> |
| <b>listDescription</b>    | <p>Specifies a string list that contains from one to four string elements, each corresponding to a string in the parameter <i>listButton</i>. Each string is a text description to be displayed with its corresponding button.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Return Values

**Table 68** ▪ SdOptionsButtons Return Values

| Return Value     | Description                                                                                      |
|------------------|--------------------------------------------------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked.                                                      |
| <b>BACK (12)</b> | Indicates that the Back button was clicked.                                                      |
| <b>101</b>       | Indicates that the button corresponding to the first string element in listButton was selected.  |
| <b>102</b>       | Indicates that the button corresponding to the second string element in listButton was selected. |
| <b>103</b>       | Indicates that the button corresponding to the third string element in listButton was selected.  |
| <b>104</b>       | Indicates that the button corresponding to the fourth string element in listButton was selected. |

**Note** ▪ To prevent the user from exiting the dialog without clicking a particular button, call the **Disable** function to disable the Next button before you call **SdOptionsButtons**.

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdOptionsButtons Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdOptionsButtons function.
 *
 * This script allows the user to select a setup type. First,
 * two lists are created, one for the setup type button icons,
 * another for the setup type descriptions. Then the buttons
 * and descriptions are added to the lists. Next, the dialog
 * is presented. When the user clicks a setup type button, the
```

```

* dialog closes and the user's selection is displayed in a
* message box.
*
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING  szTitle, szMsg;
    LIST    listButton, listDesc;
    NUMBER  nResult;
begin

    // Disable the Back and Next buttons in setup dialogs.
    Disable (BACKBUTTON);
    Disable (NEXTBUTTON);

    // Create the lists for buttons and descriptions.
    listButton = ListCreate (STRINGLIST);
    listDesc = ListCreate (STRINGLIST);

    if (listButton = LIST_NULL) || (listDesc = LIST_NULL) then
        // Report the error; then terminate.
        MessageBox ("Unable to create lists.", INFORMATION);
        abort;
    endif;

    // Add the bitmap buttons to listButton.
    ListAddString (listButton, "@12001;1;255,0,255", AFTER);
    ListAddString (listButton, "@12002;1;255,0,255", AFTER);
    ListAddString (listButton, "@12003;1;255,0,255", AFTER);
    ListAddString (listButton, "@12004;1;255,0,255", AFTER);

    // Add the descriptions to listDesc.
    ListAddString (listDesc, "Typical\n" +
        "Recommended for most computers.", AFTER);
    ListAddString (listDesc, "Portable\n" +
        "The application will be set up with " +
        "options that are useful for portable " +
        "computers.", AFTER);

        "To save disk space, none of the " +
        "optional features will be " +
        "installed.", AFTER);
    ListAddString (listDesc, "Custom\n" +
        "For advanced users and system " +
        "administrators only. You can " +
        "customize all available Setup " +
        "options.", AFTER);

    // Display the dialog.
    nResult = SdOptionsButtons (szTitle, szMsg, listButton, listDesc);

    // Display a message showing which button was selected.
    switch (nResult)
        case 101:

```

```

        MessageBox ("Typical installation selected.", INFORMATION);
    case 102:
        MessageBox ("Portable installation selected.", INFORMATION);
    case 103:
        MessageBox ("Compact installation selected.", INFORMATION);
    case 104:
        MessageBox("Custom installation selected.", INFORMATION);
    default:
        MessageBox ("SdOptionsButtons:\n\n An error occurred.", SEVERE);
endswitch;

Enable(NEXTBUTTON);

// Destroy the lists.
ListDestroy (listButton);
ListDestroy (listDesc);

end;

```

## SdOutOfDiskSpace

**Project** ▪ This information applies to InstallScript MSI projects.

The **SdOutOfDiskSpace** function displays a dialog warning the end user that the target system does not have enough available space for the application installation to take place. It also displays a list view of volumes, required space, available space, and the difference between available space and required space.

In an InstallScript MSI installation, this function is triggered when an `INSTALLMESSAGE_OUTOFDISKSPACE` message is detected. This message comes from the MSI engine.

The **SdDiskSpace2** function supersedes the **SdOutOfDiskSpace** function.

### Syntax

```
SdOutOfDiskSpace ( szTitle, szMsg );
```

## Parameters

**Table 69** ▪ SdOutOfDiskSpace Parameters

| Parameter      | Description                                                                                                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of the dialog. To display the default title (“Out of Disk Space”), pass a null string (“”) in this parameter.                                                         |
| <b>szMsg</b>   | Specifies the message to display in the dialog. This text is considered a static control. To display the default instructions for this dialog, pass a null string (“”) in this parameter. |

## Return Values

**Table 70** ▪ SdOutOfDiskSpace Return Values

| Return Value    | Description                                        |
|-----------------|----------------------------------------------------|
| <b>NEXT (1)</b> | Indicates that the end user clicked the OK button. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

# SdPatchWelcome

**Project** ▪ This information applies to InstallScript MSI projects.

The **SdPatchWelcome** function creates a dialog that displays a welcome message to the end user during a patch installation.

## Syntax

```
SdPatchWelcome ( szTitle, szMsg );
```

## Parameters

**Table 71** ▪ SdPatchWelcome Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the text to display in the title of the dialog. To display the default title ("Welcome"), pass a null string ("") in this parameter.                                                                                                                                                                                                                        |
| <b>szMsg</b>   | Specifies the message to display in the Welcome dialog. To include in this message the product name set by a previous call to <b>SdProductName</b> , insert the place holder %P anywhere in the message string. When the message is displayed, %P is replaced by the product name. To display the default welcome message, pass a null string ("") in this parameter. |

## Return Values

**Table 72** ▪ SdPatchWelcome Return Values

| Return Value    | Description                                 |
|-----------------|---------------------------------------------|
| <b>NEXT (1)</b> | Indicates that the Next button was clicked. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- If you call **SdPatchWelcome** but SD\_NDLG\_PATCHWELCOME—its dialog resource (12059)—cannot be found in the \_isres.dll file of the installation, **SdWelcome** is called automatically instead of **SdPatchWelcome** to display a dialog that is similar to the **SdPatchWelcome** dialog. In this case, the values for szTitle and szMsg are passed to the **SdWelcome** function, or custom strings are used if szTitle and szMsg are blank. This occurs only if you are patching a product whose installation was created with InstallShield Developer 7, or the dialog template has been removed manually.

Note that when this occurs, the dialog uses the same template as **SdWelcome**; thus, any changes to the **SdWelcome** dialog template affect the **SdPatchWelcome** dialog as well.

Note that in this scenario, silent mode is not supported, and it does not work correctly.

## SdPatchWelcome Example

**Project** ▪ This information applies to InstallScript MSI projects.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SdPatchWelcome function.
*
```

```

* This function displays a welcome message to the end user during
* a patch installation. This function is called in the default
* script for the OnPatchUIBefore event, which can be found in the
* Miscellaneous event category for InstallScript MSI projects.
*
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg;
begin
    // Display SdPatchWelcome with default title and message
    szTitle = "";
    szMsg   = "";
    SdPatchWelcome(szTitle, szMsg);

end;

```

## SdProductName

The **SdProductName** function sets the value of the system variable IFX\_PRODUCT\_DISPLAY\_NAME, which makes your product name available to all instances of the %P place holder. The %P place holder is found in static text fields in some Sd dialogs. In addition, some Sd dialog functions, such as SdFinish, allow you to include %P in strings passed as parameters to functions.

### Syntax

```
SdProductName ( szProductName );
```

### Parameters

**Table 73** ▪ SdProductName Parameters

| Parameter                                                                                                                                                                                                                                                                                                                                                                                            | Description                                                                                                                                                                     |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szProductName</b>                                                                                                                                                                                                                                                                                                                                                                                 | Specifies the name of the product that is being installed. This name replaces the product name placeholder (%P) wherever it appears in appropriate static fields in Sd dialogs. |
|  <p><b>Caution</b> ▪ If you want to include an ampersand (&amp;) in your product name, you must use two ampersands (&amp;&amp;) to display the name properly in end user dialogs. For example, to display “New &amp; Improved Product”, you should enter the product name as New &amp;&amp; Improved Product.</p> |                                                                                                                                                                                 |

### Return Values

This function does not return a value.

## Additional Information

Rather than call `SdProductName`, for example,

```
SdProductName( "My Product Name" );
```

you can simply assign the desired value to `IFX_PRODUCT_DISPLAY_NAME`, for example,

```
IFX_PRODUCT_DISPLAY_NAME = "My Product Name";
```

## SdProductName Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the functions SdProductName.
 *
 * The function SdProductName is called to set the product name to
 * substitute for the %P place holder, which is embedded in the
 * message strings passed to Sd dialogs.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING    szProductName, szTitle;
begin

    // Set the product name to substitute for the %P place holder.
    szProductName = "My Application";
    SdProductName (szProductName);

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Display the SdWelcome dialog. The null string in parameter
    // two specifies the default message, which uses the %P place holder.
    szTitle = "SdProductName Example";
    SdWelcome (szTitle, "");

end;
```

## SdRegisterUser

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdRegisterUser** function displays a dialog that enables the end user to specify the user name and company name for the product being installed.

You can specify default values for these fields by specifying the appropriate parameters. If you specify a null string (""), the function uses the appropriate script variable.

The Next button becomes enabled only when data exists in both edit fields. The end user cannot leave any field blank.

## Syntax

```
SdRegisterUser ( szTitle, szMsg, svName, svCompany );
```

## Parameters

**Table 74** • SdRegisterUser Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title ("User Information"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szMsg</b>     | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>svName</b>    | <p>Specifies the default value for the Name edit field when the function is called.</p> <p>If a null string ("") is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDOWNER</b> variable. For an InstallScript project, this variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode. For an InstallScript MSI project, the default value of the variable is always read from the Windows Installer property <b>USERNAME</b>.</p> <p>The function returns the value that the end user specified in this parameter. In an InstallScript installation, the function also sets the value of <b>IFX_PRODUCT_REGISTEREDOWNER</b> to the value that the end user specified. In an InstallScript MSI installation, the function automatically updates the Windows Installer property <b>USERNAME</b>.</p>              |
| <b>svCompany</b> | <p>Specifies the default value for the Company edit field when the function is called.</p> <p>If a null string ("") is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDCOMPANY</b> variable. For an InstallScript project, this variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode. For an InstallScript MSI project, the default value of the variable is always read from the Windows Installer property <b>COMPANYNAME</b>.</p> <p>The function returns the value that the end user specified in this parameter. In an InstallScript installation, the function also sets the value of <b>IFX_PRODUCT_REGISTEREDCOMPANY</b> to the value that the end user specified. In an InstallScript MSI installation, the function automatically updates the Windows Installer property <b>COMPANYNAME</b>.</p> |

## Return Values

**Table 75** • SdRegisterUser Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdRegisterUser Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdRegisterUser and SdConfirmRegistration
 * functions.
 *
 * SdRegisterUser is called to prompt for the user's name
 * and company name. These entries are then confirmed when
 * SdConfirmRegistration is called.
 *
 \*-----*/

#define REG_TITLE      "SdRegisterUser Example"
#define REG_MSG        "Please register your product now."
#define CONFIRM_TITLE  "SdConfirmRegistration Example"

#include "Ifx.h"

function OnBegin()
    STRING  svName, svCompany;
    NUMBER  nResult;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    repeat
        // Get the user's name and company name.
        SdRegisterUser (REG_TITLE, REG_MSG, svName, svCompany);

        // Confirm that the information is correct. Pass a null string in
        // parameter four since SdRegisterUser does not get a serial number.
        nResult = SdConfirmRegistration (CONFIRM_TITLE, svName, svCompany, "", 0);
    until nResult = YES;

end;
```

# SdRegisterUserEx

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdRegisterUserEx** function displays a dialog that enables the end user to specify the user name, company name, and serial number for the product being installed.

You can specify default values for these fields by specifying the appropriate parameters. If you specify a null string (""), the function uses the appropriate script variable.

The Next button becomes enabled only when data exists in all three edit fields. The end user cannot leave any field blank.

**Note** ▪ The **SdRegisterUserEx** function does not verify the serial number. To learn how to add code that verifies the serial number, see the sample serial number validation project. This sample project is in one of the Samples subfolders within the InstallShield Program Files folder. The default installation location is C:\Program Files\InstallShield\2022\Samples\InstallScript\Serial Number Validation Sample Project.

## Syntax

```
SdRegisterUserEx ( szTitle, szMsg, svName, svCompany, svSerial );
```

## Parameters

**Table 76** • SdRegisterUserEx Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“User Information”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szMsg</b>     | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>svName</b>    | <p>Specifies the default value for the Name edit field when the function is called.</p> <p>If a null string (“”) is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDOWNER</b> variable. For an InstallScript project, this variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode. For an InstallScript MSI project, the default value of the variable is always read from the Windows Installer property <b>USERNAME</b>.</p> <p>The function returns the value that the end user specified in this parameter. In an InstallScript installation, the function also sets the value of <b>IFX_PRODUCT_REGISTEREDOWNER</b> to the value that the end user specified. In an InstallScript MSI installation, the function automatically updates the Windows Installer property <b>USERNAME</b>.</p>              |
| <b>svCompany</b> | <p>Specifies the default value for the Company edit field when the function is called.</p> <p>If a null string (“”) is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDCOMPANY</b> variable. For an InstallScript project, this variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode. For an InstallScript MSI project, the default value of the variable is always read from the Windows Installer property <b>COMPANYNAME</b>.</p> <p>The function returns the value that the end user specified in this parameter. In an InstallScript installation, the function also sets the value of <b>IFX_PRODUCT_REGISTEREDCOMPANY</b> to the value that the end user specified. In an InstallScript MSI installation, the function automatically updates the Windows Installer property <b>COMPANYNAME</b>.</p> |
| <b>svSerial</b>  | <p>Specifies the default value for the Serial Number edit field when the function is called.</p> <p>If a null string (“”) is specified, the default value is the current value of the <b>IFX_PRODUCT_REGISTEREDSERIALNUM</b> variable. This variable is read from the registry in a first-time installation or the corresponding text substitution in maintenance mode.</p> <p>The function returns the value that the end user specified in this parameter. The function also sets the value of <b>IFX_PRODUCT_REGISTEREDSERIALNUM</b> to the value that the end user specified.</p>                                                                                                                                                                                                                                                                                                                              |

## Return Values

**Table 77** ▪ SdRegisterUserEx Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdRegisterUserEx Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the function SdRegisterUserEx.
 *
 * SdRegisterUserEx is called to collect installation information
 * from the user. The information is stored in a list and
 * displayed in SdShowInfoList.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING  szTitle, szMsg, svName, svCompany, svSerial;
    LIST    listData;
begin

    // Create the list.
    listData = ListCreate (STRINGLIST);

    // Set up parameters for call to SdRegisterUserEx.
    szTitle = "SdRegisterUserEx Example";
    szMsg   = "Please enter your name, company, and serial number.";

    // Retrieve registration information.
    SdRegisterUserEx (szTitle, szMsg, svName, svCompany, svSerial);

    // Add the information to the list.

```

```

ListAddString (listData, "User Information: ", AFTER);
ListAddString (listData, "          " + svName, AFTER);
ListAddString (listData, "          " + svCompany, AFTER);
ListAddString (listData, "          " + svSerial, AFTER);
ListAddString (listData, "", AFTER);

// Display user selections from list in SdShowInfoList.
szMsg  = "The user name, company name, and serial number " +
        "entered in SdRegisterUserEx.";
SdShowInfoList(szTitle, szMsg, listData);

end;

```

## SdRMFilesInUse

**Project** ▪ The *InstallScript* MSI project type support the **SdFilesInUse** function.

The **SdRMFilesInUse** function displays a dialog that includes a list box containing a list of the applications that are open and are locking files. The dialog also includes two radio buttons that allow end users to specify whether the installation should attempt to use the Restart Manager to shut down the applications that are locking files or overwrite the locked files (which most likely results in the need for a reboot to complete the installation).

Typically, the OnRMFilesInUse event handler displays this dialog in an *InstallScript* MSI installation as a response to an `INSTALLMESSAGE_FILESINUSE` message sent by the Windows Installer. When this occurs, the Windows Installer provides to the installation the list of applications that are locking files. The list of applications are passed through the `szMessage` parameter to the OnRMFilesInUse event. The event passes this information to the **SdRMFilesInUse** function through the `szMessage` parameter. The event then passes the return value from the function as the return value of the event, which causes the Windows Installer to act appropriately.

**Project** ▪ The **SdRMFilesInUse** dialog can also be called manually in *InstallScript* projects and in *InstallScript* MSI projects; however, the installation must provide the list of applications that are locking files through the `nvlistApps` parameter, and it must handle the return value appropriately. It must also interact with the Restart Manager to attempt to shut down applications that are locking files if the end user selects the corresponding option on the **SdRMFilesInUse** dialog.

### Syntax

```

SdRMFilesInUse ( byval string szTitle, byval string szMsg, byval string szFilesInUse, byref LIST
                nvlistApps, byref BOOL bvCloseRestart );

```

## Parameters

**Table 78** ▪ SdRMFilesInUse Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>        | Specifies the title of the dialog. To display the default title (Files in Use), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>szMsg</b>          | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szFilesInUse</b>   | <p>When <b>SdRMFilesInUse</b> is called by the OnRMFilesInUse event handler in an InstallScript MSI installation, this parameter specifies the list of applications that the Windows Installer found to be locking files. The function parses this string in order to display the list of applications in the dialog's list box.</p> <p>If you manually call <b>SdFilesInUse</b>, pass an empty string ("") in this parameter. Note that if nvlistApps is a valid string list, this parameter is ignored.</p>                                                                                                                                                                                                                                                                                                                                                                          |
| <b>nvlistApps</b>     | <p>When <b>SdRMFilesInUse</b> is called by the OnRMFilesInUse event handler in an InstallScript MSI installation, this parameter is specified as an uninitialized list variable—that is, a variable with a value of 0.</p> <p>If you manually call <b>SdRMFilesInUse</b>, specify a string list of applications that are locking files and that should be displayed in the dialog. Each string in the list indicates one application. (Use the <b>ListCreate</b> function and associated list functions to create and initialize the string list.)</p>  <p><b>Note</b> ▪ You must provide a variable for this parameter; you cannot specify a literal value.</p>                                                                                                                                    |
| <b>bvCloseRestart</b> | <p>Indicates the default for the aforementioned radio buttons. TRUE indicates that the close-and-restart-applications radio button is the default. FALSE indicates that the ignore-and-reboot-later radio button should be the default.</p>  <p><b>Project</b> ▪ In InstallScript MSI projects, the OnRMFilesInUse event sets the value of bvCloseRestart based on the current value of the Windows Installer property called <b>MSIRESTARTMANAGERCONTROL Property</b>.</p> <p>When the <b>SdRMFilesInUse</b> function returns, this value indicates which radio button the end user selected—TRUE for the close-and-restart-applications option or FALSE for the ignore-and-reboot-later option. Note that the function also returns the same information in the return value of the function.</p> |

## Return Values

**Table 79** ▪ SdRMFilesInUse Return Values

| Return Value                                                                                                                                                                                                                                                                                                   | Description                                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IDOK</b>                                                                                                                                                                                                                                                                                                    | Indicates that the end user selected the close-and-restart-applications option and then clicked the OK button.                                                                                         |
| <b>IDIGNORE (5)</b>                                                                                                                                                                                                                                                                                            | Indicates that the end user selected the ignore-and-reboot-later option and then clicked the OK button. Note that this value can be returned even though the dialog does not include an Ignore button. |
| <b>IDCANCEL</b>                                                                                                                                                                                                                                                                                                | Indicates that the end user clicked the Exit button.<br><br>                                                          |
| <p><b>Note</b> ▪ Note that unlike other script dialogs, this dialog does not call the <i>OnCanceling</i> event handler when the user clicks the Exit button. Therefore, if you are calling this function manually, you must handle this return value manually in order to display the Cancel Setup dialog.</p> |                                                                                                                                                                                                        |

## SdSelectFolder

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdSelectFolder** function displays folders for selection. **SdSelectFolder** enables you to offer a default selection. The end user can also enter a new folder name. **SdSelectFolder** returns only the selected or entered folder name. It cannot create the folder.

### Syntax

```
SdSelectFolder ( szTitle, szMsg, svDefGroup );
```

## Parameters

**Table 80** ▪ SdSelectFolder Parameters

| Parameter         | Description                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of the dialog. To display the default title (“Select Program Folder”), pass a null string (“”) in this parameter.                                                     |
| <b>szMsg</b>      | Specifies the message to display in the dialog. This text is considered a static control. To display the default instructions for this dialog, pass a null string (“”) in this parameter. |
| <b>svDefGroup</b> | Returns the name of the selected folder.                                                                                                                                                  |

## Return Values

**Table 81** ▪ SdSelectFolder Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- If **ProgDefGroupType** is called before calling **SdSelectFolder**, the program folders displayed by **SdSelectFolder** (Common or Personal) depend on the parameter that was passed to **ProgDefGroupType**.

## SdSelectFolder Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdSelectFolder function.
 *
 * SdSelectFolder is called to prompt the user to select a
 * folder.
 *
 * Note: Before running this script, verify that the constant
```

```

*      DEF_FOLDER references an existing folder on the
*      target computer.
*
/*-----*/

#define DEF_FOLDER "Startup"

#include "Ifx.h"

function OnBegin()
    STRING    szTitle, szMsg, svDefGroup;
begin

    // Set up parameters for call to SdSelectFolder.
    szTitle   = "SdSelectFolder Example";
    szMsg      = "";
    svDefGroup = DEF_FOLDER;

    // Get user's folder selection.
    SdSelectFolder (szTitle, szMsg, svDefGroup);

end;

```

## SdSetupCompleteError

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdSetupCompleteError** function displays a dialog to inform the end user that the installation was interrupted before it could be completed. It also informs the end user that the product has not been installed and that the target system was not modified.

### Syntax

```
SdSetupCompleteError ( szTitle, szMsg1, szMsg2 );
```

## Parameters

**Table 82** ▪ SdSetupCompleteError Parameters

| Parameter      | Description                                                                                                                                                                                                                                             |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of the dialog. To display the default title (“InstallShield Wizard Completed”), pass a null string (“”) in this parameter.                                                                                                          |
| <b>szMsg1</b>  | Specifies the message to display at the top of the dialog. To display the default instructions, which inform the end user that the installation has been interrupted and the product has not been installed, pass a null string (“”) in this parameter. |
| <b>szMsg2</b>  | Specifies the message to display at the bottom of the dialog. To display the default instructions (“Click Finish to exit the wizard”), pass a null string (“”) in this parameter.                                                                       |

## Return Values

**Table 83** ▪ SdSetupCompleteError Return Values

| Return Value    | Description                                   |
|-----------------|-----------------------------------------------|
| <b>NEXT (1)</b> | Indicates that the Finish button was clicked. |

## Additional Information

If you write your own procedural script, that is, a program/endprogram block, you can use the **SdSetupCompleteError** function to display a dialog if the end user cancels the installation. If you are using the default script event model, you do not need to call this function.

Because **SdSetupCompleteError** indicates that the installation was interrupted and cannot be completed, the Back button is disabled.

The **SdSetupCompleteError** dialog is a variation of the **SdFinish** dialog. In a silent response file (.iss), the **SdSetupCompleteError** dialog is referred to as **SdFinish**.

## SdSetupCompleteError Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SdSetupCompleteError function.
```

```

*
* SdSetupCompleteError function displays a dialog to inform
* the end user that the installation was interrupted before it
* could be completed. It also informs the end user that the
* application has not been installed and that the target system
* was not modified. This function is only available for MSI
* based projects.
*
/*-----*/

#include "Ifx.h"

function OnBegin()
    STRING    szTitle, szMsg1, szMsg2;
begin
    // Set up parameters for call to SdSetupCompleteError.
    szTitle = "SdSetupCompleteError Example";
    szMsg1  = "";
    szMsg2  = "";
    SdSetupCompleteError ( szTitle, szMsg1, szMsg2 );

end;

```

## SdSetupType

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SdSetupType** function displays a dialog that enables the end user to select one of the three standard setup types: Typical, Compact, or Custom. These setup options are displayed with standard description text. If you want to add other setup types or change the displayed setup type names or descriptions, call SdSetupTypeEx instead.

The dialog also displays a default destination path. A browse button launches a dialog that allows the end user to change the destination path, either by entering a new folder name or by selecting an existing folder from a list. If the end user enters the name of a folder that does not exist, this function automatically creates the specified folder. The fully qualified path of the specified folder is returned in svDir.

**Caution** ▪ If the end user returns to the SdSetupType dialog after using a feature dialog to select and deselect features associated with the selected setup type, those choices are lost. This occurs because the SdSetupType function automatically resets the default feature selections for the selected setup type each time it is called.

### Syntax

```
SdSetupType ( szTitle, szMsg, svDir, nReserved );
```

## Parameters

**Table 84** ▪ SdSetupType Parameters

| Parameter        | Description                                                                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“Setup Type”), pass a null string (“”) in this parameter.                                                              |
| <b>szMsg</b>     | Specifies a message to display in the dialog. This text is considered a static control. To display the default instructions for this dialog, pass a null string (“”) in this parameter. |
| <b>svDir</b>     | Specifies a default folder name. Returns the name of the folder selected by the end user.                                                                                               |
| <b>nReserved</b> | Reserved for future use. Pass 0 (zero) in this parameter.                                                                                                                               |

## Return Values

**Table 85** ▪ SdSetupType Return Values

| Return Value         | Description                                     |
|----------------------|-------------------------------------------------|
| <b>TYPICAL (301)</b> | Indicates that the user selected Typical Setup. |
| <b>COMPACT (302)</b> | Indicates that the user selected Compact Setup. |
| <b>CUSTOM (303)</b>  | Indicates that the user selected Custom Setup.  |
| <b>BACK (12)</b>     | Indicates that the Back button was clicked.     |

## Additional Information

- In an InstallScript project, if you do not display a setup type dialog, your script must do one of the following:
  - Select a setup type.
  - Call a feature selection dialog function such as SdFeatureTree.
  - Directly select features.
- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdSetupType Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*

- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the functions SdSetupType.
 *
 * This function displays a dialog that enables the end user
 * to select one of the three standard setup types: Typical,
 * Compact, or Custom.
 *
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING    szTitle, szMsg, svDir;
    NUMBER    nReserved, nResult;
begin

    // Display the SdSetupType dialog.
    szTitle = "SdSetupType Example";
    szMsg   = "";
    // Default destination folder displayed in dialog.
    svDir   = "C:\\Example";
    nReserved = 0;
    nResult = SdSetupType (szTitle, szMsg, svDir, nReserved);

    // Set TARGETDIR to the user selected destination folder.
    TARGETDIR = svDir;

    // Retrieve user selected setup type.
    switch(nResult)

        case CUSTOM: MessageBox("Custom setup type selected", 0);

        case TYPICAL: MessageBox("Typical setup type selected", 0);

        case COMPACT: MessageBox("Compact setup type selected", 0);

    endswitch;

end;

```

## SdSetupType2

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdSetupType2** function displays a dialog that enables the end user to select one of the two standard setup types: Typical or Custom. These setup options are displayed with standard description text. If you want to add other setup types or change the displayed setup type names or descriptions, call SdSetupTypeEx instead.

The dialog also displays a default destination path. A browse button launches a dialog that allows the end user to change the destination path, either by entering a new folder name or by selecting an existing folder from a list. If the end user enters the name of a folder that does not exist, this function automatically creates the specified folder. The fully qualified path of the specified folder is returned in svDir.

---

**Caution** ▪ *If the end user returns to the SdSetupType2 dialog after using a feature dialog to select and deselect features associated with the selected setup type, those choices are lost. This occurs because the SdSetupType2 function automatically resets the default feature selections for the selected setup type each time it is called.*

## Syntax

```
SdSetupType2 ( szTitle, szMsg, svDir, nReserved );
```

## Parameters

**Table 86** ▪ SdSetupType2 Parameters

| Parameter        | Description                                                                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“Setup Type”), pass a null string (“”) in this parameter.                                                              |
| <b>szMsg</b>     | Specifies a message to display in the dialog. This text is considered a static control. To display the default instructions for this dialog, pass a null string (“”) in this parameter. |
| <b>svDir</b>     | Specifies a default folder name. Returns the name of the folder selected by the end user.                                                                                               |
| <b>nReserved</b> | Reserved for future use. Pass 0 (zero) in this parameter.                                                                                                                               |

## Return Values

**Table 87** ▪ SdSetupType2 Return Values

| Return Value          | Description                                               |
|-----------------------|-----------------------------------------------------------|
| <b>COMPLETE (304)</b> | Indicates that the user selected the Complete setup type. |
| <b>TYPICAL (301)</b>  | Indicates that the user selected the Typical setup type.  |
| <b>CUSTOM (303)</b>   | Indicates that the user selected the Custom setup type.   |
| <b>BACK (12)</b>      | Indicates that the user clicked the Back button.          |

## Additional Information

- In an InstallScript project, if you do not display a setup type dialog, your script must do one of the following:
  - Select a setup type.
  - Call a feature selection dialog function such as SdFeatureTree.
  - Directly select features.
- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdSetupType2 Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*

- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the function SdSetupType2.
 *
 * SdSetupType2 is called to collect installation information
 * from the user.
 *
\*-----*/

#include "ifx.h"

function OnBegin()
    STRING    szTitle, szMsg, svDir;
    STRING    svSetupType;
    NUMBER    nResult;
begin
    // Disable Back button
    Disable(BACKBUTTON);

    // Set up parameters for call to SdSetupType2.
    szTitle = "SdSetupType2 Example";
    szMsg    = "Choose the type of installation by clicking one of the buttons.";

    // Retrieve setup type and directory information.
    svDir = TARGETDIR;
    nResult = SdSetupType2 (szTitle , szMsg, svDir, 0);
    TARGETDIR = svDir;

    // Create a string that describes the selected setup type.
    switch (nResult)

        case COMPLETE:
            svSetupType = "COMPLETE: Application will be installed " +
                "with all options.";

        case CUSTOM:
            svSetupType = "CUSTOM: You select the options that you " +
                "want installed.";

        default:
            MessageBox ("Invalid setup type selection!", SEVERE);
            abort;

    endswitch;

    MessageBox("Setup Type: " + svSetupType, 0);

end;

```

## SdSetupTypeEx

**Project** • This information applies to InstallScript MSI projects.

The **SdSetupTypeEx** function displays a dialog that enables the end user to select the setup type when you specify setup types beyond Complete and Custom. The dialog displays the names of the setup types as you specified them in the Setup Types view.

## Syntax

```
SdSetupTypeEx ( szTitle, szMsg, szReserved, svSetupType, nReserved );
```

## Parameters

**Table 88** • SdSetupTypeEx Parameters

| Parameter          | Description                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>     | Specifies the title of the dialog. To display the default title (“Setup Type”), pass a null string (“”) in this parameter.                                                                      |
| <b>szMsg</b>       | Specifies the message to be displayed in the dialog. To display the default instructions for this dialog, pass a null string (“”) in this parameter.                                            |
| <b>szReserved</b>  | Pass a null string (“”) in this parameter. No other value is allowed.                                                                                                                           |
| <b>svSetupType</b> | Specifies a default setup type and returns the setup type selected by the end user. The string returned in this parameter will match the name of the setup type as you specified it in the IDE. |
| <b>nReserved</b>   | Pass zero in this parameter. No other value is allowed.                                                                                                                                         |

## Return Values

**Table 89** • SdSetupTypeEx Return Values

| Return Value     | Description                                  |
|------------------|----------------------------------------------|
| <b>0</b>         | Indicates that SdSetupTypeEx was successful. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked.  |

## Additional Information

- In an InstallScript project, if you do not display a setup type dialog, your script must do one of the following:
  - Select a setup type
  - Call a feature selection dialog function such as SdFeatureTree.
  - Directly select features.
- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdSetupTypeEx Example

**Project** • This information applies to InstallScript MSI projects.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdSetupTypeEx function.
 *
 * The SdSetupTypeEx function displays a dialog that enables
 * the end user to select the setup type when you specify setup
 * types beyond Complete and Custom. The dialog
 * displays the names of the setup types you create in the IDE's
 * Setup Types view.
 *
 * This sample sets the default setup type in the SdSetupTypeEx
 * dialog to "Complete".
 *
\*-----*/

#include "ifx.h"

function OnBegin()
    STRING szTitle, szMsg, szReserved, svSetupType;
    NUMBER nReserved;
begin
    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set up the variables to pass as parameters to SdSetupTypeEx.
    szTitle= "SdSetupTypeEx Sample";
    szMsg= "";
    szReserved = "";

    // Specifies a default setup type (as specified in the Setup Type
    // view) and returns the setup type selected by the end user
    svSetupType = "Complete";
    nReserved = 0;

    // Display the SdSetupTypeEx dialog.
    SdSetupTypeEx(szTitle, szMsg, szReserved, svSetupType, nReserved);

    // Display a MessageBox with the setup type selected by the end user
    MessageBox("Setup Type selected: " + svSetupType, 0);

end;
```

## SdShowAnyDialog

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdShowAnyDialog** function displays a custom or modified dialog. This function is recommended for advanced users only.

## Syntax

```
SdShowAnyDialog ( szTitle, szID, nID, nReserved );
```

## Parameters

**Table 90** ▪ SdShowAnyDialog Parameters

| Parameter        | Description                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>   | Specifies the title of the dialog. To display the default title (“Welcome”), pass a null string (“”) in this parameter.                           |
| <b>szID</b>      | Specifies the string identifier that identifies the dialog. If this parameter contains a null string (“”), SdShowAnyDialog uses the value in nID. |
| <b>nID</b>       | Specifies the numeric value that identifies the dialog. If you entered a value in szID, this parameter is ignored.                                |
| <b>nReserved</b> | Pass zero in this parameter. No other value is allowed.                                                                                           |

## Return Values

**Table 91** ▪ SdShowAnyDialog Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.
- In order to use the SdShowAnyDialog function, you must know the ID of either the modified dialog in \_isres.dll or the custom dialog in \_isuser.dll that you want to display.
- If the dialog has only static controls, you do not need to modify the SdShowAnyDialog script file. However, if your dialog has any other controls, you must modify the Sdsadlg.rul file—located in the Script\Isrt\Src folder of your InstallShield program files folder—in order to process the feedback from the user.

## SdShowAnyDialog Example

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdShowAnyDialog function.
 *
 * SdShowAnyDialog is called twice, first with the ID of the
 * Welcome dialog, then with the ID of the Finish dialog
 * box.
 *
 \*-----*/

#define TITLE "SdShowAnyDialog Example"

#include "Ifx.h"

function OnBegin()
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set up the product name so that it can be displayed
    // in place of the %P placeholder in Sd dialogs.
    SdProductName ("ExampApp");

    // Display the SdWelcome dialog.
    SdShowAnyDialog (TITLE, "", SD_NDLG_WELCOME, 0);

    // Display the SdFinish dialog.
    SdShowAnyDialog (TITLE, "", SD_NDLG_FINISH, 0);

end;
```

## SdShowDlgEdit1

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdShowDlgEdit1** function creates a general dialog that displays a message and one single-line edit field. You can specify a title for the dialog.

## Syntax

```
SdShowDlgEdit1 ( szTitle, szMsg, szField1, svEdit1 );
```

## Parameters

**Table 92** • SdShowDlgEdit1 Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>  | Specifies the title of the dialog. To display the default title (“Edit Data”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                                                            |
| <b>szMsg</b>    | Specifies the message to display in the dialog. To include in this message the product name set by a previous call to <a href="#">SdProductName</a> , insert the place holder %P anywhere in the message string. When the message is displayed, %P is replaced by the product name.                                                                                                                                                                                  |
| <b>szField1</b> | Specifies a field name to be displayed to the left of the edit field. The default field name is “Field 1:”. To display the default name, pass a null string (“”) in this parameter. The maximum number of characters that can be displayed is approximately 10. The actual maximum depends on the combined width of each character in the field name. If the field name exceeds the available space, it will be truncated on the right when the dialog is displayed. |
| <b>svEdit1</b>  | Specifies an initial value for the edit field; returns the value of the edit field when the dialog is closed.                                                                                                                                                                                                                                                                                                                                                        |

## Return Values

**Table 93** • SdShowDlgEdit1 Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdShowDlgEdit1 Example

**Project** • This information applies to the following project types:

- *InstallScript*

- *InstallScript MSI*

```

/*-----*
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdShowDlgEdit1 function.
 *
 * This example script calls SdShowDlgEdit1 to obtain the name
 * of a folder, which is then displayed in a message box.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, szField1, svEdit1;
begin
    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set up parameters for call to SdShowDlgEdit1.
    szTitle = "SdShowDlgEdit1 Example";
    szMsg = "Please choose a folder for YourApp:";
    szField1 = "Target:";
    svEdit1 = "C:\\Example\\Target\\YourApp";

    // Get a target folder name from the user.
    if (SdShowDlgEdit1 (szTitle, szMsg, szField1, svEdit1) < 0) then
        // Report an error.
        MessageBox ("SdShowDlgEdit1 failed.", SEVERE);

    else
        // Display svEdit1 string variable.
        sprintfBox (INFORMATION, szTitle, "You selected %s", svEdit1);

    endif;

end;

```

## SdShowDlgEdit2

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdShowDlgEdit2** function creates a general dialog that displays a message and two single-line edit fields. You can specify a title for the dialog.

### Syntax

```
SdShowDlgEdit2 ( szTitle, szMsg, szField1, szField2, svEdit1, svEdit2 );
```

## Parameters

**Table 94** • SdShowDlgEdit2 Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>  | Specifies the title of the dialog. If you pass a null string ("" ) in this parameter, the default title ("Edit Data") is displayed.                                                                                                                                                                                                                                                                                                                                          |
| <b>szMsg</b>    | Specifies the message to display in the dialog. To include in this message the product name set by a previous call to <a href="#">SdProductName</a> , insert the place holder %P anywhere in the message string. When the message is displayed, %P is replaced by the product name.                                                                                                                                                                                          |
| <b>szField1</b> | Specifies a field name to be displayed to the left of the first edit field. The default field name is "Field 1:" ; to display the default name, pass a null string ("" ) in this parameter. The maximum number of characters that can be displayed is approximately 10. The actual maximum depends on the combined width of each character in the field name. If the field name exceeds the available space, it will be truncated on the right when the dialog is displayed. |
| <b>szField2</b> | Specifies a field name for the second edit field. "Field 2:" is the default.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>svEdit1</b>  | Specifies an initial value for the first edit field; returns the value of the first edit field when the dialog is closed.                                                                                                                                                                                                                                                                                                                                                    |
| <b>svEdit2</b>  | Specifies an initial value for the second edit field; returns the value of the second edit field when the dialog is closed.                                                                                                                                                                                                                                                                                                                                                  |

## Return Values

**Table 95** • SdShowDlgEdit2 Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdShowDlgEdit2 Example

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdShowDlgEdit2 function.
 *
 * This script displays a dialog that prompts the user to
 * specify a source folder and a target folder. It then displays
 * the user's selections in a message box.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, szField1, szField2, svEdit1, svEdit2;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set up parameters for call to SdShowDlgEdit2.
    szTitle = "SdShowDlgEdit2 Example";
    szMsg = "All files within the Source directory will be copied into " +
           "the Target directory.";
    szField1 = "Source:";
    szField2 = "Target:";
    svEdit1 = "C:\\Example\\Source";
    svEdit2 = "C:\\Example\\Target";

    // Get source and target folder names.
    if (SdShowDlgEdit2 (szTitle, szMsg, szField1, szField2,
                       svEdit1, svEdit2) < 0) then
        // Report an error.
        MessageBox ("SdShowDlgEdit2 failed.", SEVERE);

    else
        // Display the user's selections.
        sprintfBox (INFORMATION, szTitle, "svEdit1: %s\nsvEdit2: %s",
                   svEdit1, svEdit2);
    endif;

end;

```

## SdShowDlgEdit3

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdShowDlgEdit3** function creates a general dialog that displays a message and three single-line edit fields. You can specify a title for the dialog in szTitle.

### Syntax

```
SdShowDlgEdit3 ( szTitle, szMsg, szField1, szField2, szField3, svEdit1, svEdit2, svEdit3 );
```

## Parameters

**Table 96** ▪ SdShowDlgEdit3 Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>  | Specifies the title of the dialog. If you pass a null string (""), the default title ("Edit Data") is displayed.                                                                                                                                                                                                                                                                                                                                                                     |
| <b>szMsg</b>    | Specifies the message to display in the dialog. To include in this message the product name set by a previous call to <a href="#">SdProductName</a> , insert the place holder %P anywhere in the message string. When the message is displayed, %P is replaced by the product name.                                                                                                                                                                                                  |
| <b>szField1</b> | Specifies a field name to be displayed to the left of the first edit field. The default field name is "Field 1:". To display the default name, pass a null string (""), in this parameter. The maximum number of characters that can be displayed is approximately 10. The actual maximum depends on the combined width of the characters in the field name. If the field name is too large for the available space, it will be truncated on the right when the dialog is displayed. |
| <b>szField2</b> | Specifies a field name for the second edit field. "Field 2:" is the default.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>szField3</b> | Specifies a field name for the third edit field. "Field 3:" is the default.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>svEdit1</b>  | Specifies an initial value for the first edit field; returns the value of the first edit field when the dialog is closed.                                                                                                                                                                                                                                                                                                                                                            |
| <b>svEdit2</b>  | Specifies an initial value for the second edit field; returns the value of the second edit field when the dialog is closed.                                                                                                                                                                                                                                                                                                                                                          |
| <b>svEdit3</b>  | Specifies an initial value for the third edit field; returns the value of the third edit field when the dialog is closed.                                                                                                                                                                                                                                                                                                                                                            |

## Return Values

**Table 97** ▪ SdShowDlgEdit3 Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdShowDlgEdit3 Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdShowDlgEdit3 function.
 *
 * This script calls SdShowDlgEdit3 to get three folder names
 * from the user. These are then displayed in a message box.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, szField1, szField2, szField3, svEdit1, svEdit2;
    STRING svEdit3;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set up parameters for call to SdShowDlgEdit3.
    szTitle   = "SdShowDlgEdit3 Example";
    szMsg      = "Please choose up to two valid directories in Backup: or " +
                "Alternate: to back up the source directory.\n\n";
    szField1   = "Directory";
    szField2   = "Backup";
    szField3   = "Alternate";
    svEdit1    = "C:\\YourApp";
    svEdit2    = "C:\\Backup1";
    svEdit3    = "C:\\Backup2";

    // Get three folder names from the user.
    if (SdShowDlgEdit3 (szTitle, szMsg, szField1, szField2, szField3,
                        svEdit1, svEdit2, svEdit3) < 0) then
        // Report an error.
        MessageBox ("SdShowDlgEdit3 failed.", SEVERE);
    else
        // Display the folder names specified by the user.
        szMsg = "svEdit1: %s\n\svEdit2: %s\n\svEdit3: %s";
        sprintfBox (INFORMATION, szTitle, szMsg, svEdit1, svEdit2, svEdit3);

    endif;

end;
```

# SdShowFileMods

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdShowFileMods** function creates a dialog that displays changes you want to make to a file. These choices are available:

- Make changes to the target file.
- Make changes to the alternate file, which is a copy of the target file, but incorporates changes.
- Do not make any changes. SdShowFileMods does not make changes to a file. You must write those changes into your script using the appropriate file functions.

## Syntax

```
SdShowFileMods ( szTitle, szMsg, szTargetFile, szAltFile, listChanges, nvSelection );
```

## Parameters

**Table 98** • SdShowFileMods Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>      | Specifies the title of the dialog. To display the default title ("Modifying File"), pass a null string ("") in this parameter.                                                                                                                                                                        |
| <b>szMsg</b>        | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                       |
| <b>szTargetFile</b> | Specifies the name of the file to modify. This will be displayed with the first radio button.                                                                                                                                                                                                         |
| <b>szAltFile</b>    | Specifies an alternate name to give the file if the end user decides to make the changes. This will be displayed with the second radio button. To use the name of file specified in szTargetFile with the extension .bak, pass a null string ("") in this parameter.                                  |
| <b>listChanges</b>  | Specifies the name of a string list that contains the list of changes to make to the file. This list is placed in a multi-line edit field that allows the end user to select the changes to be implemented.                                                                                           |
| <b>nvSelection</b>  | Returns the ID of the button selected by the end user: <ul style="list-style-type: none"> <li>● <b>101</b>—"Let Setup modify the &lt;szTargetFile&gt; file."</li> <li>● <b>102</b>—"Save the required changes to &lt;szAltFile&gt; file."</li> <li>● <b>103</b>—"Do not make any changes."</li> </ul> |

## Return Values

**Table 99** • SdShowFileMods Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## SdShowFileMods Example

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdShowFileMods function.
 *
 * This script displays a list of changes to make to a specified
 * file. The user may elect to make those changes, to save the
 * changes to a new file, or not to make or save the changes.
 *
 * Note: SdShowFileMods does not itself modify or create files.
 *       It simply obtains the user's choice.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szTitle, szMsg, szTargetFile, szAltFile;
    NUMBER nvSelection;
    LIST    listID;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set up variables for call to SdShowFileMods.
    szTitle = "SdShowFileMods Example";

    szMsg = "Choose what option to take";
    szTargetFile = "Example.txt";
    szAltFile = "Example.new";

    // Create a list to hold file modification details.
    listID = ListCreate (STRINGLIST);

    // Add file modification details to the list.
    ListAddString (listID, "PATH = C:\\Example", AFTER);
    ListAddString (listID, "FILES = 40", AFTER);

    // Present options and get the user's choice.
    SdShowFileMods (szTitle, szMsg, szTargetFile, szAltFile,
                    listID, nvSelection);

    // Handle the user's selection.
    switch(nvSelection)
```

```

    case 101:
        sprintfBox (INFORMATION, szTitle, "Setup modified the %s file.",
                    szTargetFile);

    case 102:
        sprintfBox (INFORMATION, szTitle, "The required changes were saved " +
                    "to the %s file.", szAltFile);

    case 103:
        sprintfBox (INFORMATION, szTitle, "No changes were made.");

endswitch;

end;

```

## SdShowInfoList

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdShowInfoList** function creates a dialog that displays a list of scrollable messages. SdShowInfoList can display lists of up to approximately 57,200 characters.

### Syntax

```
SdShowInfoList ( szTitle, szMsg, listID );
```

## Parameters

**Table 100** ▪ SdShowInfoList Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of the dialog. To display the default title (“Information”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                |
| <b>szMsg</b>   | Specifies the message to display on one line above the information box. If the message is too long to fit on one line, it is truncated on the right. If the message includes a newline escape sequence (\n), the text following that escape sequence is not displayed. To display the default message (“Text”), pass a null string (“”) in this parameter. |
| <b>listID</b>  | Specifies the list of messages to display in the dialog. All messages that appear in the dialog are read only.                                                                                                                                                                                                                                             |

## Return Values

**Table 101** ▪ SdShowInfoList Return Values

| Return Value     | Description                                 |
|------------------|---------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the Next button was clicked. |
| <b>BACK (12)</b> | Indicates that the Back button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdShowInfoList Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdShowInfoList function.
 *
 * This script calls GetSystemInfo to retrieve information about
 * the user's system. The ListAdd function is used to add the
 * information to a string list, which is displayed by
```

```

* calling SdShowInfoList function.
*
\*-----*/

#include "Ifx.h"

function OnBegin()
    STRING  szTitle, szMsg, svReturn, szInfo;
    NUMBER  nvReturn;
    LIST    listInfo;
begin

    // Create a list to hold system information.
    listInfo = ListCreate (STRINGLIST);

    // Check if the system has a CD-ROM drive.
    GetSystemInfo (CDROM, nvReturn, svReturn);

    if (nvReturn = TRUE) then
        szInfo = "Your machine has a CD-ROM Drive.";
    else
        szInfo = "Your machine does not have a CD-ROM drive.";
    endif;

    // Add the CD-ROM info to the list.
    ListAddString (listInfo, szInfo, AFTER);

    // Check the time on the system.
    GetSystemInfo (TIME, nvReturn, svReturn);
    Sprintf (szInfo, "The time now is %s.", svReturn);

    // Add the time to the list.
    ListAddString (listInfo, szInfo, AFTER);

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set up title and message parameters for call to SdShowInfoList.
    szTitle = "SdShowInfoList Example";
    szMsg    = "Following is some information related to your system:";

    // Display the information.
    SdShowInfoList (szTitle, szMsg, listInfo);

end;

```

## SdShowMsg

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdShowMsg** function provides a simple way to display an informative message that remains on screen while script processing continues.

The **SdShowMsg** function opens or closes a small modeless window that displays the message specified by `szMsg`. When `bShow` is `TRUE`, the window is opened, the message is displayed in the window, and processing continues with the next statement in the script. Note that the **SdShowMsg** window is positioned at the center of the setup window. When `bShow` is `FALSE`, `szMsg` is ignored and the **SdShowMsg** window is closed.

**Note** ▪ When the **SdShowMsg** window is open, subsequent calls to **SdShowMsg** with `TRUE` in the second parameter are ignored. To change the message, you must first close the window by calling **SdShowMsg** with `FALSE` in the second parameter and then call **SdShowMsg** again with the new message in `szMsg` and `TRUE` in the second parameter.

## Syntax

```
SdShowMsg ( szMsg, bShow );
```

## Parameters

**Table 102** ▪ SdShowMsg Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b> | <p>Specifies the message to display in the window. To display the default message (“Setup is searching for installed features”), pass a null string (“”) in this parameter. This parameter is ignored when <code>bShow</code> is <code>FALSE</code>.</p> <p><b>SdShowMsg</b> is designed to display a message on a single line. Do not embed newline characters (\n) in <code>szMsg</code>.</p>  <p><b>Note</b> ▪ The <b>SdShowMsg</b> window is sized horizontally to display the value of <code>szMsg</code> on a single line. If the length of the message exceeds the maximum width of the window, the message is truncated to fit the window.</p> |
| <b>bShow</b> | <p>Specifies whether to open or close the window. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Opens the window if it is not already open.</li> <li>● <b>FALSE</b>—Closes the window if it is open.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Return Values

This function always returns 0.

## Additional Information

- The dialog that is displayed by the **SdShowMsg** function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

- The Dialog Editor does not support dialogs, such as **SdShowMsg**, that do not have a title bar. Therefore, this dialog is not displayed in the Dialogs view as one of the dialogs that you can edit. To customize this dialog, use the **SdShowMsg** call.

## SdShowMsg Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SdShowMsg dialog.
 *
 * SdShowMsg is called to display a message for three seconds.
 * It's then called again to remove the message from the screen.
 * A final call to SdShowMsg displays another message.
 *
 \*-----*/

#include "Ifx.h"

function OnBegin()
    STRING szMsg;
begin

    // Display a message on the screen.
    szMsg = "This message will appear for three seconds.";
    SdShowMsg (szMsg, TRUE);

    // Delay for 3 seconds.
    Delay (3);

    // Remove message from screen.
    SdShowMsg (szMsg, FALSE);

    // Display another message on the screen.
    szMsg = "This is another message which will " +
        "appear for a mere three seconds.";
    SdShowMsg (szMsg, TRUE);
    Delay(3);

    // Remove message from screen.
    SdShowMsg (szMsg, FALSE);

end;

// Source file:Is5fn157.rul
```

# SdStartCopy

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdStartCopy** function creates a multi-line edit field displaying the settings and selections made during the installation. The end user can click the Back button on the dialog to return to previous dialogs in order to change settings as required. Call SdStartCopy after retrieving the selections from the user, but before beginning the file transfer process.

Use a string list to collect the information obtained during the installation. You then pass the string list to SdStartCopy in the parameter listData. SdStartCopy displays the list and allows the user to verify that the information is correct before continuing with the file transfer process.

## Syntax

```
SdStartCopy (szTitle, szMsg, listData);
```

## Parameters

**Table 103** ▪ SdStartCopy Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>  | Specifies the title of the dialog. To display the default title ("Start Copying Files"), pass a null string ("") in this parameter.                                                                                                                                                                             |
| <b>szMsg</b>    | Specifies the message to display in the static text field above the multi-line edit field. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                      |
| <b>listData</b> | Specifies a string list of information retrieved from the end user. SdStartCopy automatically places each element into the multi-line edit field. If listData has not been initialized by a call to <a href="#">ListCreate</a> , the multi-line edit field is hidden and only the static text field is visible. |

## Return Values

**Table 104** ▪ SdStartCopy Return Values

| Return Value     | Description                                       |
|------------------|---------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the user selected the Next button. |
| <b>BACK (12)</b> | Indicates that the user selected the Back button. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdStartCopy Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the function SdStartCopy, with the use of
 * SdRegisterUserEx and SdSetupType.
 *
 * SdRegisterUserEx and SdSetupType are called to collect
 * installation information from the user. The information is

// Call SdStartCopy to display user selections.
nResult = SdStartCopy (szTitle, szMsg, listData);

// Handle the user's exit from the SdStartCopy dialog.
switch(nResult)
    case NEXT:
        MessageBox ("SdStartCopy successful.", INFORMATION);
    case BACK:
        goto SetupTypeLabel;
    default:
        MessageBox ("SdStartCopy failed.", SEVERE);
endswitch;

end;

```

## SdStartCopy2

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdStartCopy2** function informs the user that the file transfer process is about to begin. The user can click the Back button to return to previous dialogs in order to change settings as required. Call SdStartCopy2 after retrieving the selections from the user, but before beginning the file transfer process.

### Syntax

```
SdStartCopy2 ( szTitle, szMsg );
```

## Parameters

**Table 105** ▪ SdStartCopy2 Parameters

| Parameter      | Description                                                                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of the dialog. To display the default title ("Ready to Install the Program"), pass a null string ("") in this parameter.               |
| <b>szMsg</b>   | Specifies the message to display in the static text field. To display the default instructions for this dialog, pass a null string ("") in this parameter. |

## Return Values

**Table 106** ▪ SdStartCopy2 Return Values

| Return Value              | Description                                          |
|---------------------------|------------------------------------------------------|
| <b>NEXT</b>               | Indicates that the user selected the Install button. |
| <b>BACK</b>               | Indicates that the user selected the Back button.    |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the dialog could not be displayed.    |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdStartCopy2 Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the functions SdProductName, SdWelcome,
 * SdStartCopy2, and SdFinish.
 *
 * First, SdProductName is called to set the product name to
 * substitute for the %P place holder, which is embedded in the
 * message strings passed to SdWelcome and SdFinish.
 *
 * Next, SdWelcome is called to display a welcome message and
 * then SdStartCopy2 is called. Finally, a call to SdFinish
 * completes the setup process by giving the user final options.
```

```

*
* Note: Before running this script, set the preprocessor
*       constants so that they reference the fully-qualified
*       names of the Windows Notepad executable and a valid
*       text file on the target system.
*
\*-----*/

//Assign the name of a text file to READMEFILE

#define NOTEPAD "C:\\Windows\\Notepad.exe"
#define READMEFILE ""

    STRING    szProductName, szTitle, szMsg, szFeatures;
    STRING    szMsg1, szMsg2, szOpt1, szOpt2;
    BOOL      bvOpt1, bvOpt2;
    NUMBER    nReturn;

#include "ifx.h"

function OnBegin()
begin

    // Set the product name to substitute for the %P place holder.
    szProductName = "My Application";
    SdProductName (szProductName);

SdWelcomeLabel:
    szTitle = "SdWelcome Example";

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Display the SdWelcome dialog. The null string in parameter
    // two specifies the default message, which uses the %P place holder.
    SdWelcome (szTitle, "");

    // Enable the Back button in setup dialogs.
    Enable (BACKBUTTON);

SdStartCopy2Label:
    szTitle = "SdStartCopy2 Example";
    // Display the SdStartCopy2 dialog.
    if (SdStartCopy2 (szTitle, szMsg) = BACK) then
        goto SdWelcomeLabel;
    endif;

    // The %P place holder is embedded in several of the string
    // parameters that will be passed to SdFinish.
    szTitle = "SdFinish Example";
    szMsg1 = "%P Setup is almost complete.\n" +
        "Choose the options you want below.";
    szMsg2 = "Click Finish to complete %P Setup.";
    szOpt1 = "I would like to view the README file.";

```

```
szOpt2 = "I would like to launch %P.";

// Display the SdFinish dialog.
SdFinish (szTitle, szMsg1, szMsg2, szOpt1, szOpt2, bvOpt1, bvOpt2);

if (bvOpt1) then
    // Display the read me file.
    LaunchAppAndWait (NOTEPAD, READMEFILE, LAAW_OPTION_WAIT);
endif;

if (bvOpt2) then
    // Because this example does not actually install an
    // application, a message box is displayed in place of
    // the call to LaunchApp that would normally be made here,
    // for example:
    // LaunchApp (TARGETDIR^PROGRAMEXECUTABLE,"");

    sprintfBox (INFORMATION, szTitle, "Launch %s here.", szProductName);
endif;

end;
```

# SdSubstituteProductInfo

The **SdSubstituteProductInfo** function replaces any occurrences of the %P, %VS, and %VI placeholders in svString with the values of the system variables IFX\_PRODUCT\_DISPLAY\_NAME, IFX\_PRODUCT\_DISPLAY\_VERSION, and IFX\_INSTALLED\_DISPLAY\_VERSION. You can use this function before calling a function, such as MessageBox, that does not automatically perform this replacement before displaying strings.

## Syntax

```
SdSubstituteProductInfo ( svString );
```

## Parameters

Table 107 ▪ SdSubstituteProductInfo Parameters

| Parameter | Description                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------|
| svString  | Specifies the string containing placeholders; returns the string with the placeholders replaced. |

## Return Values

This function does not return a value.

# SdWelcome

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdWelcome** function creates a dialog that displays a welcome message to the end user.

## Syntax

```
SdWelcome ( szTitle, szMsg );
```

## Parameters

**Table 108** ▪ SdWelcome Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the text to display in the title of the dialog. To display the default title (“Welcome”), pass a null string (“”) in this parameter.                                                                                                                                                                                                                                                                                                           |
| <b>szMsg</b>   | Specifies the message to display in the Welcome dialog. To include in this message the product name set by a previous call to <b>SdProductName</b> , insert the place holder %P anywhere in the message string. When the message is displayed, %P is replaced by the product name. To display the default welcome message (“Welcome to the %P Setup program. This program will install %P on your computer”), pass a null string (“”) in this parameter. |

## Return Values

**Table 109** ▪ SdWelcome Return Values

| Return Value    | Description                                 |
|-----------------|---------------------------------------------|
| <b>NEXT (1)</b> | Indicates that the Next button was clicked. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdWelcome Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
```

```

* Demonstrates the function SdWelcome.
*
* The SdWelcome function displays a dialog that welcomes
* the end user.
*
\*-----*/

#include "ifx.h"

function OnBegin()
    STRING  szTitle, szProductName;
begin

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set the product name to substitute for the %P place holder.
    szProductName = "My Application";
    SdProductName (szProductName);

    szTitle = "SdWelcome Example";

    // Display the SdWelcome dialog. The null string in parameter
    // two specifies the default message, which uses the %P place holder.
    SdWelcome (szTitle, "");

end;

```

## SdWelcomeMaint

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SdWelcomeMaint** function displays a dialog that is intended for use at the beginning of a maintenance setup (that is, the re-running of a setup that has already been run). The dialog contains Modify, Repair, and Remove option buttons.

### Syntax

```
SdWelcomeMaint (szTitle, szMsg, nType);
```

## Parameters

**Table 110** ▪ SdWelcomeMaint Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                          |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of the dialog. To display the default title ("Welcome"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                              |
| <b>szMsg</b>   | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                                                                                                      |
| <b>nType</b>   | Specifies which option button is the default selection. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>MODIFY</b>—The Modify button is the default selection.</li> <li>● <b>REPAIR</b>—The Repair button is the default selection.</li> <li>● <b>REMOVEALL</b>—The Remove button is the default selection.</li> </ul> |

## Return Values

**Table 111** ▪ SdWelcomeMaint Return Values

| Return Value           | Description                                                                              |
|------------------------|------------------------------------------------------------------------------------------|
| <b>MODIFY (301)</b>    | Indicates that the Modify button was selected when the end user clicked the Next button. |
| <b>REPAIR (302)</b>    | Indicates that the Repair button was selected when the end user clicked the Next button. |
| <b>REMOVEALL (303)</b> | Indicates that the Remove button was selected when the end user clicked the Next button. |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SdWelcomeMaint Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*

    // Disable the Back button in setup dialogs.
    Disable (BACKBUTTON);

    // Set the product name to substitute for the %P place holder.
    szProductName = "My Application";
    SdProductName (szProductName);

    szTitle = "SdWelcomeMaint Example";
    //Specifies which option button is the default selection.
    nType = REMOVEALL;

    // Display the SdWelcomeMaint dialog. The null string in
    // parameter two specifies the default message, which uses
    // the %P place holder.
    nReturn = SdWelcomeMaint (szTitle, "", nType);

    switch(nReturn)

    case MODIFY: MessageBox("SdWelcomeMaint selection: Modify", 0);

    case REPAIR: MessageBox("SdWelcomeMaint selection: Repair", 0);

    case REMOVEALL: MessageBox("SdWelcomeMaint selection: Remove", 0);

    endswitch;

end;

```

## SeekBytes

The **SeekBytes** function repositions the file pointer within an open binary file. You can move the file pointer a specific number of bytes relative to its current position or relative to the beginning or end of the file.

**Note** - Before calling *SeekBytes*, you must open the file (which can be a file on the Internet) in binary mode by calling *OpenFileMode* and *OpenFile*. When you are finished writing bytes to the file, call *CloseFile* to close the file.

## Syntax

```
SeekBytes ( nFileHandle, nBytes, nPosition );
```

## Parameters

**Table 112** ▪ SeekBytes Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nFileHandle</b> | Specifies the file handle of a file that has been opened in binary mode.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>nBytes</b>      | Specifies the number of bytes to move the file pointer relative to the position specified by nPosition. If nBytes is a positive number, the file pointer is moved toward the end of the file. If nBytes is a negative number, the file pointer is moved toward the beginning of the file.                                                                                                                                                           |
| <b>nPosition</b>   | Specifies the location in the file from which to move the pointer nBytes. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>FILE_BIN_CUR</b>—Moves the pointer nBytes from its current position.</li> <li>• <b>FILE_BIN_END</b>—Moves the pointer nBytes from the end of the file.</li> <li>• <b>FILE_BIN_START</b>—Moves the pointer nBytes from the beginning of the file.</li> </ul> |

## Return Values

**Table 113** ▪ SeekBytes Return Values

| Return Value  | Description                                                        |
|---------------|--------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully repositioned the pointer. |
| <b>&lt; 0</b> | Indicates that the function was unable to reposition the pointer.  |

## SeekBytes Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
```

```

* InstallShield Example Script
*
* Demonstrates the ReadBytes and SeekBytes functions.
*
* SeekBytes is called to position a file pointer to a
* specific location in a file that has been opened in binary
* mode. ReadBytes then reads a specific number of bytes,
* starting at this location. The bytes are read into a string,
* which is then displayed in a message box.
*
* Note: The defined constants EXAMPLE_DIR and EXAMPLE_BIN must
*       be set to an existing directory and file on the target
*       system.
*
\*-----*/

#define EXAMPLE_DIR "C:\\\"
#define EXAMPLE_BIN "Example.bin"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SeekBytes(HWND);

function ExFn_SeekBytes(hMSI)
  STRING svString;
  NUMBER nvFileHandle;
begin

  // Set the file mode to read/write.
  OpenFileMode (FILE_MODE_BINARY);

  // Open a binary file.
  if (OpenFile (nvFileHandle, EXAMPLE_DIR, EXAMPLE_BIN) < 0) then

    // Report an error; then abort.
    sprintfBox (SEVERE, "CopyBytes Example", "Could not open %s.",
               EXAMPLE_BIN);
    abort;

  endif;

  // Set the file pointer to the 16th byte in the file.
  SeekBytes (nvFileHandle, 15, FILE_BIN_START);

  // Read the next twenty-eight bytes into svString.
  if (ReadBytes (nvFileHandle, svString, 0, 28) < 0) then

    // Report an error.
    MessageBox ("ReadBytes failed.", SEVERE);
  else

    // Display the string.
    sprintfBox (INFORMATION, "ReadBytes Example", "Bytes read: %s",
               svString);

```

```

endif;

// Close the file.
CloseFile (nvFileHandle);

end;

```

## SelectDir

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SelectDir** function has been superseded by the **SelectDirEx** function. You should use the **SelectDirEx** function when creating new installations. You can call the **SelectDirEx** function with nFlags set to BIF\_RETURNONLYFSDIRS | BIF\_EDITBOX to achieve the same result as calling the **SelectDir** function with bCreate set to FALSE.

The **SelectDir** function displays a dialog that lets the end user specify the folder into which the application will be installed. The end user can enter a fully qualified folder name or select an existing folder from a list. If the end user enters an invalid folder name or an unqualified folder name, a message box is displayed to prompt the end user to enter a valid name. The fully qualified name of the selected folder is returned in svDir.

If the specified folder does not exist and the parameter bCreate is TRUE, **SelectDir** automatically creates the specified folder. If the parameter bCreate is set to FALSE and a non-existent folder is selected, the end user is not informed, and **SelectDir** does not create it. In this case, it is up to you to handle the selection contained in svDir.

**Note** • **SelectDir** is called automatically when the end user clicks the Browse button in the dialogs that are presented by **AskDestPath**, **SdAskDestPath**, and other *InstallScript* functions that obtain a folder name.

Windows displays this dialog; therefore, the installation cannot change the text of the buttons on the dialog. Windows displays the button text—"Yes" and "No" on English-based systems—in the language of the operating system; no manual localization of this text is required. If you need to display a more flexible dialog, call a Windows API function directly or use a custom dialog.

### Syntax

```
SelectDir ( szTitle, szMsg, svDir, bCreate );
```

## Parameters

**Table 114** ▪ SelectDir Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b> | Specifies the title of this dialog. To display the default title ("Choose Folder"), pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                 |
| <b>szMsg</b>   | Specifies the message you want to display in this dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                      |
| <b>svDir</b>   | Specifies the name of a folder that will appear as the default selection. Returns the fully qualified name of the folder selected by the end user.                                                                                                                                                                                                                                                             |
| <b>bCreate</b> | Specifies whether or not you want InstallShield to create the specified folder if it does not already exist. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Indicates that the folder should be created if it does not exist.</li> <li>• <b>FALSE</b>—Indicates that the folder should not be created if it does not exist.</li> </ul> |

## Return Values

If bCreate is FALSE, this function returns one of the following values:

**Table 115** ▪ SelectDir Return Values when bCreate is FALSE

| Return Value        | Description                                                   |
|---------------------|---------------------------------------------------------------|
| <b>IDOK (1)</b>     | Indicates that the OK button was selected.                    |
| <b>IDCANCEL (2)</b> | Indicates that the CANCEL button was selected.                |
| <b>&lt; 0</b>       | Indicates that the function was unable to display the dialog. |

If bCreate is TRUE, this function returns one of the following values:

**Table 116** ▪ SelectDir Return Values when bCreate is TRUE

| Return Value        | Description                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>IDCANCEL (2)</b> | Indicates that the CANCEL button was selected.                                                                    |
| <b>0</b>            | Indicates that the OK button was selected and the function was able to create the folder specified, if necessary. |
| <b>&lt; 0</b>       | Indicates that the function failed to display the dialog and/or create the specified folder.                      |

## Additional Information

- The dialog that is displayed by this function cannot be displayed with a skin; it appears the same, regardless of whether you have specified a skin.
- In early versions of InstallShield Professional, when bCreate was set to TRUE and the end user selected a folder that did not exist, a confirmation message box was displayed asking whether the folder should be created. This message box proved to be confusing to many end users, so it has been removed from InstallShield.

## SelectDir Example

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SelectDir function.
 *
 * This script calls SelectDir to display a dialog that
 * allows the user to specify a folder. If the specified folder
 * does not exist, it is not created. Instead, an error message
 * is displayed and the SelectDir dialog is displayed again.
 *
 \*-----*/

#define TITLE_TEXT "SelectDir Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SelectDir(HWND);

function ExFn_SelectDir(hMSI)
    STRING  szTitle, szMsg, svDir;
    BOOL    bCreate, bFolderExists;
    NUMBER  nResult;
begin

    // Loop until user cancels or selects an existing folder.
    repeat

        // Set a default folder for the SelectDir dialog.
        svDir = INSTALLDIR;

        // Set the message to display in the SelectDir dialog.
        szMsg  = "Please choose an existing folder.";

        // Get an existing folder name from the user. The fourth
```

```

// parameter indicates that a non-existing folder should
// not be created.
nResult = (SelectDir (TITLE_TEXT, szMsg, svDir, FALSE) < 0) ;

if nResult = 0 then

    // Determine whether the folder exists.
    bFolderExists = ExistsDir (svDir);

    if bFolderExists = NOTEXISTS then
        // The folder does not exist. Ask user to select again.
        szMsg = "%s does not exist.\nPlease choose an existing folder.";
        sprintfBox (WARNING, szTitle, szMsg, svDir);
    endif;

endif;

until (nResult = CANCEL) || (bFolderExists = EXISTS);

if (bFolderExists = EXISTS) then

    // Display the name of the selected folder.
    sprintfBox (INFORMATION, szTitle, "You selected %s.", svDir);

endif;

end;

```

## SelectDirEx

**Project** - This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SelectDirEx** function displays a dialog that enables the end user to select a folder into which the application will be installed. An edit box can also be displayed to enable the end user to specify a new folder.

This function calls the Windows API function SHBrowseForFolder to display the dialog. For more information on SHBrowseForFolder, see the Windows API documentation.

**Note** - Windows displays this dialog; therefore, the installation cannot change the text of the buttons on the dialog. Windows displays the button text—"Yes" and "No" on English-based systems—in the language of the operating system; no manual localization of this text is required. If you need to display a more flexible dialog, call a Windows API function directly or use a custom dialog.

### Syntax

```
SelectDirEx ( szTitle, szMsg, szEditBoxStatusText, szTreeControlStatusText, nFlags, svDir );
```

## Parameters

**Table 117** ▪ SelectDirEx Parameters

| Parameter                      | Description                                                                                                                                                                                       |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>                 | Specifies the title of this dialog. To display the default title Choose Folder, pass a null string ("") in this parameter.                                                                        |
| <b>szMsg</b>                   | Specifies the message you want to display in this dialog. To display the default instructions for this dialog (Please choose the installation folder), pass a null string ("") in this parameter. |
| <b>szEditBoxStatusText</b>     | Specifies the static text that accompanies the edit box when nFlags specifies BIF_EDITBOX. If nFlags does not specify BIF_EDITBOX, this parameter is ignored.                                     |
| <b>szTreeControlStatusText</b> | Specifies the static text to accompany the dialog's tree control when nFlags specifies BIF_STATUSTEXT. If nFlags does not specify BIF_STATUSTEXT, this parameter is ignored.                      |

**Table 117** ■ SelectDirEx Parameters (cont.)

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nFlags</b> | <p>Specifies the appearance and functionality of the dialog that is displayed by the function by specifying the same flags that are used for the Windows structure BROWSEINFO. Note that if you pass BIF_BROWSEFORCOMPUTER or BIF_BROWSEFORPRINTER, no edit box is displayed. Pass any of the following constants:</p> <ul style="list-style-type: none"> <li>● <b>BIF_BROWSEFORCOMPUTER</b>—Enables the end user to select a computer on the network. The Network Neighborhood is preselected in the tree control and the OK button is enabled only if a valid computer name is selected in the tree control. No edit box is displayed, even if BIF_EDITBOX is specified.</li> <li>● <b>BIF_BROWSEFORPRINTER</b>—Enables the end user to select a printer. The My Computer folder is preselected in the tree control. Only computers that include at least one printer are displayed under the Network Neighborhood folder. The OK button is enabled only if a valid printer is selected in the tree control. No edit box is displayed, even if BIF_EDITBOX is specified.</li> <li>● <b>BIF_DONTGOBELOWDOMAIN</b>—Network folders below the domain level are not displayed in the tree control.</li> <li>● <b>BIF_RETURNFSANCESTORS</b>—Shows folders above svDir.</li> <li>● <b>BIF_RETURNONLYFSDIRS</b>—Browses file system folders.</li> </ul> <p>The following constants specify other aspects of the dialog:</p> <ul style="list-style-type: none"> <li>● <b>BIF_STATUSTEXT</b>—Displays status text in the dialog.</li> <li>● <b>BIF_EDITBOX</b>—Adds an edit field to the Browse dialog. The end user can type a folder name in the edit box. The text specified in the SzEditBoxStaticText parameter appears above the edit box, unless BIF_BROWSEFORCOMPUTER or BIF_BROWSEFORPRINTER is specified. When the end user clicks OK, SelectDirEx checks whether a valid folder name is entered. If not, an error message appears and the dialog is not closed.</li> </ul> |
| <b>svDir</b>  | <p>Specifies the name of a folder that will appear as the default selection. Returns the fully qualified name of the folder selected by the end user. If a valid folder name that exists on the target system is specified in this parameter, the specified folder is preselected in the tree control.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Return Values

**Table 118** ▪ SelectDirEx Return Values

| Return Value        | Description                                                   |
|---------------------|---------------------------------------------------------------|
| <b>IDOK (1)</b>     | Indicates that the end user clicked the OK button.            |
| <b>IDCANCEL (2)</b> | Indicates that the end user clicked the Cancel button.        |
| <b>&lt; 0</b>       | Indicates that the function was unable to display the dialog. |

## Additional Information

The dialog that is displayed by this function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## SelectDirEx Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SelectDirEx function.
 *
 * This sample script calls SelectDirEx to display a dialog
 * that allows the user to specify a folder. If the specified
 * folder does not exist, it is not created; instead, an error
 * message is displayed and the SelectDirEx dialog is displayed
 * again.
 *
 \*-----*/

#include "ifx.h"

function OnBegin()
    STRING  szTitle, szMsg, svDir;
    BOOL    bCreate, bFolderExists;
    NUMBER  nResult;
begin
    // Loop until user cancels or selects an existing folder.
    repeat
        // Set a default folder for the SelectDirEx dialog.
        svDir = TARGETDIR;

        // Set the title to display in the SelectDirEx dialog.
```

```

szTitle = "SelectDirEx Example";

// Set the message to display in the SelectDirEx dialog.
szMsg = "Please choose an existing folder.";

// Get an existing folder name from the user.
nResult = (SelectDirEx (szTitle, szMsg, "", "",
    BIF_RETURNONLYFSDIRS | BIF_EDITBOX, svDir ) < 0) ;

if nResult = 0 then
    // Determine whether the folder exists.
    bFolderExists = ExistsDir (svDir);

    if bFolderExists = NOTEXISTS then
        // The folder does not exist. Ask user to select again.
        szMsg = "%s does not exist.\nPlease choose an existing folder.";

endif;
end;

```

## SelectFolder

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SelectFolder** function displays a dialog that enables the end user to enter the name of a program folder in an edit field or select a program folder from a list. The function automatically displays all program folders on the system. A default folder name passed in svDefFolder is displayed in the edit field. The selected folder name is returned in svResultFolder.

**Caution** ▪ If the specified folder does not exist, you must call *CreateProgramFolder* to create it; *SelectFolder* will not create the folder.

### Syntax

```
SelectFolder ( szTitle, szDefFolder, svResultFolder );
```

## Parameters

**Table 119** ▪ SelectFolder Parameters

| Parameter             | Description                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>        | Specifies the title of the dialog. To display the default title, Select Program Folder, pass a null string ("" ) in this parameter. |
| <b>szDefFolder</b>    | Specifies the name of the folder to display as the default folder.                                                                  |
| <b>svResultFolder</b> | Returns the name of the folder selected or specified by the end user.                                                               |

## Return Values

**Table 120** ▪ SelectFolder Return Values

| Return Value     | Description                                          |
|------------------|------------------------------------------------------|
| <b>NEXT (1)</b>  | Indicates that the end user clicked the Next button. |
| <b>BACK (12)</b> | Indicates that the end user clicked the Back button. |
| <b>&lt; 0</b>    | Indicates that the function was unsuccessful.        |

## Additional Information

To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SelectFolder Example

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SelectFolder function.
 *
 * First, SelectFolder is called to get a folder selection from
 * the user. Then the name of the selected folder is displayed.
 *
\*-----*/

#define TITLE_TEXT "SelectFolder Example"

```

```
// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SelectFolder(HWND);

function ExFn_SelectFolder(hMSI)
    STRING svResultFolder;
    NUMBER nReturn;
begin

    // Get folder selection from user. Make "Startup" the
    // default selection
    nReturn = SelectFolder (TITLE_TEXT, "Startup", svResultFolder);

    if (nReturn < 0) then

        // Report an error.
        MessageBox ("SelectFolder failed.", SEVERE);

    else

        // Display the name of the selected folder.
        sprintfBox (INFORMATION, TITLE_TEXT,
            "Selected folder: %s", svResultFolder);

    endif;

end;
```

## SendMessage

The **SendMessage** function sends a message to one or more windows. SendMessage does not return control to the setup script until the message has been processed. The SendMessage function is a direct pass-through to the Windows API SendMessage. Consult the Windows programming documentation for detailed information.

**Note** ▪ To send a message using the parameter *nMsg* or to handle return values, you must define constants in your script that are equivalent to the constants defined in *Windows.h*. You cannot use *#include* to include *Windows.h* in your script.

### Syntax

```
SendMessage ( nHwnd, nMsg, nwParam, nIParam );
```

## Parameters

**Table 121** ▪ SendMessage Parameters

| Parameter      | Description                                                             |
|----------------|-------------------------------------------------------------------------|
| <b>nHwnd</b>   | Specifies the handle that identifies the window to receive the message. |
| <b>nMsg</b>    | Specifies the message to send to the window(s).                         |
| <b>nwParam</b> | Specifies additional message information.                               |
| <b>nlParam</b> | Specifies additional message information.                               |

## Return Values

SendMessage returns the value it receives from calling the Windows API of the same name. The return value depends on the message received by the Windows API SendMessage. Consult Windows programming documentation for detailed information on messages returned by the Windows API SendMessage.

## Additional Information

### Task

**To pass string data in the fourth parameter of SendMessage, do the following:**

- For projects converted from InstallShield Professional, include the required function declaration by doing one of the following:
  - Remove the preprocessor constant `ISINCLUDE_NO_WINAPI_H` from the Preprocessor Defines box, which is available on the Compile/Link tab on the Settings dialog box. (To access this dialog box, click Settings on the Build menu.)
  - Place the following code in your script:

```
prototype USER.SendMessageA(HWND, NUMBER, NUMBER, BYREF STRING);
```

(For projects created with InstallShield, `ISRTWindows.h` is included by default in `Ifx.h`, which in turn is included by default in the script.)

- Call the function as in the following example:

```
USER.SendMessageA( hWnd, LB_GETTEXT, nResult, sResult);
```

## SendMessage Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* Demonstrates the FindWindow and SendMessage functions.
*
* This script launches Windows Notepad and then calls
* FindWindow to locate the Notepad window. Next, it calls
* SendMessage to maximize the window; after a three-second
* delay, it calls SendMessage again to minimize the
* window. When the script ends, Windows NotePad remains
* open but minimized. Note that the parameters passed to
* SendMessage are Windows system messages whose values
* are defined as constants in this script.
*
* Note: Before running this script, set the preprocessor
*       constant NOTEPAD so that it references the fully-
*       qualified name of the Windows Notepad executable.
*
\*-----*/

#define NOTEPAD "C:\\Windows\\Notepad.exe"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SendMessage(HWND);

function ExFn_SendMessage(hMSI)
    NUMBER nMsg, nwParam, nlParam;
    HWND nHwnd;
begin

    // Do not display the setup's background window.
    Disable (BACKGROUND);

    // Open the Windows Notepad.
    if (LaunchApp (NOTEPAD, "") < 0 ) then
        MessageBox ("Unable to launch Notepad.", SEVERE);
        abort;
    endif;

    // Wait three seconds so we can view the window before
    // it's maximized.
    Delay (3);

    // Retrieve the handle of the Notepad window. The first
    // parameter is the window class. A null string in the
    // second parameter specifies the topmost Notepad window.
    nHwnd = FindWindow ("Notepad", "");

    if (nHwnd = NULL) then
        MessageBox ("Unable to find the Notepad window.", SEVERE);
    else
        // Send system command to maximize the window.
        SendMessage (nHwnd, WM_SYSCOMMAND, SC_MAXIMIZE, 0);

        // Wait three seconds so we can view the window
        // before it's minimized.

```

```

        Delay (3);

        // Send system command to minimize the window.
        SendMessage (nHwnd, WM_SYSCOMMAND, SC_MINIMIZE, nIParam);
    endif;

end;

```

## ServiceAddService

The **ServiceAddService** function adds the service specified by `szServiceName` to the list of services registered on the system. You can customize the `SERVICE_IS_PARAMS` structure to control additional service creation elements. **ServiceAddService** does not install any files; you must install the service file yourself during the installation.

If the service specified by `szServiceName` already exists, **ServiceAddService** reconfigures it to the parameters specified in the function call. If the existing service is running when **ServiceAddService** is called, the installation attempts to stop the service before attempting to reconfigure the service. If the service cannot be stopped, **ServiceAddService** reconfigures the service and sets `BATCH_INSTALL` to non-zero so that Windows can complete the service reconfiguration after reboot.

### Syntax

```

ServiceAddService ( szServiceName, szServiceDisplayName, szServiceDescription, szServicePathFile,
                    bStartService, szStartServiceArgs );

```

## Parameters

**Table 122** ▪ ServiceAddService Parameters

| Parameter                   | Description                                                                                                                                       |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szServiceName</b>        | Specifies the name of the service.                                                                                                                |
| <b>szServiceDisplayName</b> | Specifies the display name of the service.                                                                                                        |
| <b>szServiceDescription</b> | Specifies the service description.                                                                                                                |
| <b>szServicePathFile</b>    | Specifies the path to the service executable file and, optionally, command line parameters that are passed to the service whenever it is started. |
| <b>bStartService</b>        | Specifies whether to start the service after adding it.                                                                                           |
| <b>szStartServiceArgs</b>   | Specifies command line arguments that are passed to the service only when it is started by the installation.                                      |

## Return Values

**Table 123** ▪ ServiceAddService Return Values

| Return Value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully added or reconfigured the service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>&lt; ISERR_SUCCESS</b>  | <p>Indicates that the function was unable to add or reconfigure the service.</p> <p>If this function fails, additional error information may be available by calling <b>GetExtendedErrInfo</b> and checking the value of its third argument. (This value typically indicates the result of internally calling the Windows API function <b>GetLastError</b> after a call to a Windows API function failed.)</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

## Additional Information

If logging is enabled when **ServiceAddService** is called, the service is logged for uninstallation whether or not the service existed already and is removed when the application is uninstalled. If you are adding a service that should not be uninstalled, disable logging before calling this function.

Note that the publicly defined structures—**SERVICE\_IS\_PARAMS** and **SERVICE\_IS\_STATUS**—are not used when the service is uninstalled automatically. If you want to specify non-default settings when uninstalling the service, disable logging when adding the service and then remove the service manually during uninstallation by calling **ServiceRemoveService** directly from the script.

## ServiceExistsService

The **ServiceExistsService** function determines whether the service specified by `szServiceName` is registered on the system.

### Syntax

```
ServiceExistsService ( szServiceName );
```

### Parameters

**Table 124** ▪ ServiceExistsService Parameters

| Parameter            | Description                        |
|----------------------|------------------------------------|
| <b>szServiceName</b> | Specifies the name of the service. |

### Return Values

**Table 125** ▪ ServiceExistsService Return Values

| Return Value | Description                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TRUE</b>  | Indicates that the service is registered on the system.                                                                                            |
| <b>FALSE</b> | Indicates that the service is not registered on the system, or that the setup could not determine whether the service is registered on the system. |

## ServiceGetServiceState

The **ServiceGetServiceState** function returns in `nvServiceState` the state of the service that is specified by `szServiceName`.

### Syntax

```
ServiceGetServiceState ( szServiceName, nvServiceState );
```

## Parameters

**Table 126** ▪ ServiceGetServiceState Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szServiceName</b>  | Specifies the name of the service.                                                                                                                                                                                                                                                                                                                                |
| <b>nvServiceState</b> | <p>Returns one of the following Windows-defined constants specifying the state of the service:</p> <ul style="list-style-type: none"> <li>• SERVICE_STOPPED</li> <li>• SERVICE_START_PENDING</li> <li>• SERVICE_STOP_PENDING</li> <li>• SERVICE_RUNNING</li> <li>• SERVICE_CONTINUE_PENDING</li> <li>• SERVICE_PAUSE_PENDING</li> <li>• SERVICE_PAUSED</li> </ul> |

## Return Values

**Table 127** ▪ ServiceGetServiceState Return Values

| Return Value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function retrieved the state of the service. Additional status information is available in the SERVICE_IS_STATUS system variable.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>&lt; ISERR_SUCCESS</b>  | <p>Indicates that the function was unable to retrieve the state of the service.</p> <p>If this function fails, additional error information may be available by calling <b>GetExtendedErrInfo</b> and checking the value of its third argument. (This value typically indicates the result of internally calling the Windows API function <b>GetLastError</b> after a call to a Windows API function failed.)</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

# ServiceInitParams

The **ServiceInitParams** function initializes the SERVICE\_IS\_PARAMS system variable's members to the following default values. This function is called automatically during setup initialization.

## Syntax

```
ServiceInitParams ( );
```

## System Variable Members

**Table 128** ▪ ServiceInitParams System Variable Members

| Parameter                                       | Default Value             |
|-------------------------------------------------|---------------------------|
| <b>SERVICE_IS_PARAMS.IpMachineName</b>          | NULL                      |
| <b>SERVICE_IS_PARAMS.IpDatabaseName</b>         | NULL                      |
| <b>SERVICE_IS_PARAMS.dwDesiredAccess</b>        | SERVICE_ALL_ACCESS        |
| <b>SERVICE_IS_PARAMS.dwServiceType</b>          | SERVICE_WIN32_OWN_PROCESS |
| <b>SERVICE_IS_PARAMS.dwStartType</b>            | SERVICE_AUTO_START        |
| <b>SERVICE_IS_PARAMS.dwErrorControl</b>         | SERVICE_ERROR_IGNORE      |
| <b>SERVICE_IS_PARAMS.IpLoadOrderGroup</b>       | NULL                      |
| <b>SERVICE_IS_PARAMS.IpdwTagId</b>              | NULL                      |
| <b>SERVICE_IS_PARAMS.IpDependencies</b>         | NULL                      |
| <b>SERVICE_IS_PARAMS.IpServiceStartName</b>     | NULL                      |
| <b>SERVICE_IS_PARAMS.IpPassword</b>             | NULL                      |
| <b>SERVICE_IS_PARAMS.nStartServiceWaitCount</b> | INFINITE                  |
| <b>SERVICE_IS_PARAMS.nStopServiceWaitCount</b>  | INFINITE                  |

## Parameters

None.

## Return Values

**Table 129** ▪ ServiceInitParams Return Values

| Return Value  | Description                                 |
|---------------|---------------------------------------------|
| ISERR_SUCCESS | This function always returns ISERR_SUCCESS. |

# ServiceRemoveService

The **ServiceRemoveService** function removes the service that is specified by `szServiceName` from the service control manager database. If the service is running when the function is called, the installation stops the service before removing the service.

## Syntax

```
ServiceRemoveService ( szServiceName );
```

## Parameters

**Table 130** ▪ ServiceRemoveService Parameters

| Parameter            | Description                        |
|----------------------|------------------------------------|
| <b>szServiceName</b> | Specifies the name of the service. |

## Return Values

**Table 131** ▪ ServiceRemoveService Return Values

| Return Value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function removed the service from the service control manager database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>&lt; ISERR_SUCCESS</b>  | <p>Indicates that the function was unable to remove the service.</p> <p>If this function fails, additional error information may be available by calling <b>GetExtendedErrInfo</b> and checking the value of its third argument. (This value typically indicates the result of internally calling the Windows API function <b>GetLastError</b> after a call to a Windows API function failed.)</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

# ServiceStartService

The **ServiceStartService** function starts the service that is specified by szServiceName. If the service is running when the function is called, the installation stops it and then restarts it.

This function waits for the service to reach its running state before returning; it waits indefinitely as long as the service is updating the dwCheckPoint member of the SERVICE\_IS\_STATUS structure at least every dwWaitHint milliseconds. To force the function to return after a specific time interval, regardless of whether the service has started, you can change the nStartServiceWaitCount member of the structured variable SERVICE\_IS\_PARAMS to the appropriate time in seconds.

## Syntax

ServiceStartService ( szServiceName, szStartServiceArgs );

## Parameters

Table 132 ▪ ServiceStartService Parameters

| Parameter          | Description                                                     |
|--------------------|-----------------------------------------------------------------|
| szServiceName      | Specifies the name of the service.                              |
| szStartServiceArgs | Specifies a comma-delimited string of arguments to the service. |

## Return Values

Table 133 ▪ ServiceStartService Return Values

| Return Value     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| >= ISERR_SUCCESS | Indicates that the function started the service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| < ISERR_SUCCESS  | <p>Indicates that the function was unable to start the service.</p> <p>If this function fails, additional error information may be available by calling <b>GetExtendedErrInfo</b> and checking the value of its third argument. (This value typically indicates the result of internally calling the Windows API function <b>GetLastError</b> after a call to a Windows API function failed.)</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

# ServiceStopService

The **ServiceStopService** function stops the service that is specified by szServiceName.

This function waits for the service to stop before returning; it waits indefinitely as long as the service is updating the `dwCheckPoint` member of the `SERVICE_IS_STATUS` structure at least every `dwWaitHint` milliseconds. To force the function to return after a specific time interval, regardless of whether the service has stopped, you can change the `nStopServiceWaitCount` member of the structured variable `SERVICE_IS_PARAMS` to the appropriate time in seconds.

## Syntax

```
ServiceStopService ( szServiceName );
```

## Parameters

**Table 134** ▪ ServiceStopService Parameters

| Parameter            | Description                        |
|----------------------|------------------------------------|
| <b>szServiceName</b> | Specifies the name of the service. |

## Return Values

**Table 135** ▪ ServiceStopService Return Values

| Return Value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function stopped the service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>&lt; ISERR_SUCCESS</b>  | <p>Indicates that the function was unable to stop the service.</p> <p>If this function fails, additional error information may be available by calling <b>GetExtendedErrInfo</b> and checking the value of its third argument. (This value typically indicates the result of internally calling the Windows API function <b>GetLastError</b> after a call to a Windows API function failed.)</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a>.</p> |

## Additional Information

# ServiceStopServiceEx2

The **ServiceStopServiceEx2** function stops the service that is specified by `szServiceName`, `bStopDependencies`.

This function stops the services and its dependencies.

## Syntax

```
ServiceStopServiceEx2 ( szServiceName, bStopDependencies);
```

## Parameters

**Table 136** ▪ ServiceStopServiceEx2 Parameters

| Parameter                | Description                                                                                                                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szServiceName</b>     | Specifies the name of the service.                                                                                                                                                                                                                                                                     |
| <b>bStopDependencies</b> | Specifies to stop all or specific services. <ul style="list-style-type: none"> <li>• True - Stops all the dependent services</li> <li>• False - Stops only a specific service which doesn't have any dependent services, or one which has dependencies but all of them are already stopped.</li> </ul> |

## Return Values

**Table 137** ▪ ServiceStopServiceEx2 Return Values

| Return Value                  | Description                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b>    | Indicates that the function has stopped the service<br>Indicates that the function has already stopped the service |
| <b>&lt; ISERR_GEN_FAILURE</b> | Indicates that the function failed the service                                                                     |

## Additional Information

# SetColor

The **SetColor** function sets the color of the setup background.

**Note** ▪ This function is not supported for use in Basic MSI setup projects.

## Syntax

```
SetColor ( nObject, nColor );
```

## Parameters

**Table 138** ▪ SetColor Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nObject</b> | <p>Specifies the user interface object to change. Pass the following predefined constant in this parameter:</p> <ul style="list-style-type: none"><li>● <b>BACKGROUND</b>—Indicates the background of the setup window. The default color is solid teal: RGB (0,128,128).</li></ul> |

**Table 138** ▪ SetColor Parameters (cont.)

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nColor</b> | <p>Specifies a color for the background.</p> <p>For a gradient background color, pass one of the following constants:</p> <ul style="list-style-type: none"> <li>• BK_BLUE</li> <li>• BK_GREEN</li> <li>• BK_MAGENTA</li> <li>• BK_ORANGE</li> <li>• BK_PINK</li> <li>• BK_RED</li> <li>• BK_YELLOW</li> </ul> <p>For a solid background color, pass one of the following constants or call the <b>RGB</b> function to indicate a particular color (using the values provided in the parentheses):</p> <ul style="list-style-type: none"> <li>• BK_SOLIDBLACK (0, 0, 0)</li> <li>• BK_SOLIDBLUE (0, 0, 255)</li> <li>• BK_SOLIDGREEN (0, 255, 0)</li> <li>• BK_SOLIDMAGENTA (255, 0, 127)</li> <li>• BK_SOLIDORANGE (255, 127, 0)</li> <li>• BK_SOLIDPINK (255, 0, 255)</li> <li>• BK_SOLIDRED (255, 0, 0)</li> <li>• BK_SOLIDWHITE (255, 255, 255)</li> <li>• BK_SOLIDYELLOW (255, 255, 0)</li> </ul> <p>For a custom color, pass the function RGB in this parameter.</p> <div>  </div> <hr/> <p><b>Note</b> ▪ When using an RGB value, you can apply the same method as described in the programming manuals for Microsoft Windows. You specify the mixture of RED, GREEN, and BLUE colors to “mix” the color. Use a number from 0 to 255 to represent the amount of color to use. You must use literal numbers in the parameters of the RGB macro. You can also use a long value that represents the RGB color instead of the RGB statement. To achieve a smoothing effect (gradient) when the background is painted with a custom color, bitwise OR the color with the predefined constant BK_SMOOTH. Note that the smoothing effect is better with 256 colors enabled.</p> |

## Return Values

**Table 139** ▪ SetColor Return Values

| Return Value | Description                                                                           |
|--------------|---------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully set the color of the object.                 |
| < 0          | Indicates that the function was unable to set the color of the user interface object. |

## SetColor Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SetColor function.
 *
 * The first call to SetColor sets the background color to solid
 * blue. The second call sets the background color to gradient
 * red. The last call sets the background color to an RGB value.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SetColor(HWND);

function ExFn_SetColor(hMSI)
begin
    // Change the background color to solid blue.
    if (SetColor (BACKGROUND, BK_SOLIDBLUE) < 0) then
        MessageBox ("SetColor failed.", SEVERE);
    endif;

    // Delay for three seconds.
    Delay (3);

    // Change the background color to gradient red.
    if (SetColor (BACKGROUND, BK_RED) < 0) then
        MessageBox ("SetColor failed.", SEVERE);
    endif;

    // Delay for three seconds.
    Delay (3);

    // Change the background color to custom magenta.
```

```

    if (SetColor (BACKGROUND, RGB(100, 50, 150)) < 0) then
        MessageBox ("SetColor failed.", SEVERE);
    endif;

    Delay (3);

end;

```

## SetDialogTitle

The **SetDialogTitle** function changes the titles that appear in the title bars of some common built-in dialogs. Specify the dialog using the parameter `nDialogId`. If you do not use `SetDialogTitle`, the default title appears.

When you set the title for a particular dialog, InstallShield uses that title for every instance of that type of dialog until you use `SetDialogTitle` to change the title again. You must call `SetDialogTitle` separately for each type of dialog whose title you wish to change.

---

**Note** ▪ *InstallShield creates message boxes using standard Windows message box functions. Windows determines the OK and Cancel button text for these message boxes. InstallShield cannot control the text used in the buttons inside Windows message boxes.*

### Syntax

```
SetDialogTitle ( nDialogId, szTitle );
```

## Parameters

**Table 140** ▪ SetDialogTitle Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nDialogId</b> | <p>Identifies the built-in dialog whose title is to be changed. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>DLG_ASK_OPTIONS</b>—Changes the title of the <a href="#">AskOptions</a> dialog.</li> <li>• <b>DLG_ASK_PATH</b>—Changes the title of the <a href="#">AskPath</a> dialog.</li> <li>• <b>DLG_ASK_TEXT</b>—Changes the title of the <a href="#">AskText</a> dialog.</li> <li>• <b>DLG_ASK_YESNO</b>—Changes the title of the <a href="#">AskYesNo</a> dialog.</li> <li>• <b>DLG_ENTER_DISK</b>—Changes the title of the <a href="#">EnterDisk</a> dialog.</li> <li>• <b>DLG_MSG_INFORMATION</b>—Changes the title of the Information-style <a href="#">MessageBox</a>.</li> <li>• <b>DLG_MSG_SEVERE</b>—Changes the title of the Severe-style <a href="#">MessageBox</a>.</li> <li>• <b>DLG_STATUS</b>—Changes the title of the dialog-style progress indicator. You must re-enable the dialog-style progress indicator by calling <code>Enable(STATUSDLG)</code> after calling <code>SetDialogTitle</code> with the <code>DLG_STATUS</code> option in order for the title change to take effect.</li> <li>• <b>DLG_MSG_WARNING</b>—Changes the title of the Warning-style <a href="#">MessageBox</a>.</li> <li>• <b>DLG_USER_CAPTION</b>—Changes the <a href="#">MessageBox</a> caption when you use the user-defined message box styles.</li> </ul> |
| <b>szTitle</b>   | Specifies the new title.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Return Values

**Table 141** ▪ SetDialogTitle Return Values

| Return Value  | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully changed the title of the dialog. |
| <b>&lt; 0</b> | Indicates that the function was unable to change the title of the dialog. |

## SetDialogTitle Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
```

```

* InstallShield Example Script
*
* Demonstrates the SetDialogTitle function.
*
* SetDialogTitle is called to change the title of the
* AskYesNo dialog.
*
\*-----*/

#define TITLE_TEXT "SetDialogTitle Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SetDialogTitle(HWND);

function ExFn_SetDialogTitle(hMSI)
    NUMBER nCheck1, nCheck2;
begin

    // Set the title for the AskYesNo dialog.
    if (SetDialogTitle (DLG_ASK_YESNO, TITLE_TEXT) < 0) then

        // Report an error.
        MessageBox ("SetDialogTitle failed.", SEVERE);

    else

        // Display the AskYesNo dialog with its new title.
        AskYesNo ("Did SetDialogTitle change this title?", YES);

    endif;

end;

```

## SetDisplayEffect

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SetDisplayEffect** function specifies the display effect to be used when displaying bitmaps or metafiles with the PlaceBitmap function or when displaying billboards. Once the display effect has been set, all bitmaps subsequently displayed by PlaceBitmap, or billboards, are displayed with this effect until a new effect is set by another call to SetDisplayEffect.

Display effects occur only when placing bitmaps or billboards. No display effects are used when removing bitmaps or billboards.

---

**Note** ▪ A bitmap that is displayed by *PlaceBitmap* with the option *BITMAPICON*, *FULLSCREEN*, *FULLSCREENSIZE*, or *TILED* is not displayed with display effects. Instead it is displayed normally. For more information, see [PlaceBitmap](#).

## Syntax

```
SetDisplayEffect ( nEffect );
```

## Parameters

**Table 142** ▪ SetDisplayEffect Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nEffect</b> | <p>Specifies a display effect. Pass one of the following predefined constants in this parameter. Note that these constants are exclusive; you cannot use the bitwise OR operator and specify more than one. Moreover, this parameter has no effect when BITMAPICON, FULLSCREEN, FULLSCREENSIZE, or TILED is specified when displaying a bitmap with PlaceBitmap.</p> <ul style="list-style-type: none"> <li>• <b>EFF_FADE</b>—The bitmap or billboard slowly fades in and out.</li> <li>• <b>EFF_REVEAL</b>—The bitmap or billboard gradually fills in from the center toward all sides.</li> <li>• <b>EFF_HORZREVEAL</b>—The bitmap or billboard gradually scrolls out horizontally from its center.</li> <li>• <b>EFF_HORZSTRIPE</b>—A section of the bitmap or billboard fills in horizontally from the outside in; then the remainder fills in from the center out.</li> <li>• <b>EFF_VERTSTRIPE</b>—A section of the bitmap or billboard fills in vertically from the outside in; then the remainder fills in from the center out.</li> <li>• <b>EFF_BOXSTRIPE</b>—A section of the bitmap or billboard fills in from all sides; then the remainder fills in toward all sides.</li> <li>• <b>EFF_NONE</b>—This option is the default setting. Use it to clear the display effects after calling one of the other options.</li> </ul> |

**Note** ▪ Only **EFF\_REVEAL** and **EFF\_HORZREVEAL** work with metafiles.

## Return Values

**Table 143** ▪ SetDisplayEffect Return Values

| Return Value  | Description                                                       |
|---------------|-------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully set the display effect.  |
| <b>&lt; 0</b> | Indicates that the function was unable to set the display effect. |

## SetDisplayEffect Example

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SetDisplayEffect function.
*
```

```

* This script displays the same bitmap seven times, with a
* different effect each time.
*
* Note: In order for this script to run correctly, you must
*       set the constant BITMAP_FILE so that it references an
*       existing bitmap file on the target system. The
*       constant BITMAP_ID can be any integer in this example
*       since the bitmap is not loaded from a DLL and there
*       are no other bitmaps on the screen.
*
\*-----*/

#define BITMAP_FILE "C:\\Windows\\Forest.BMP"

// ID to use for the bitmap.
#define BITMAP_ID 1

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_SetDisplayEffect(HWND);

function ExFn_SetDisplayEffect(hMSI)
begin

    // Open a background window so the effect's name can
    // be shown in the title bar each time the bitmap
    // is displayed.
    Enable (FULLWINDOWMODE);
    Enable (BACKGROUND);

    // 1. Display bitmap using the box stripe effect.
    SetDisplayEffect (EFF_FADE);

    SetTitle ("Fade effect", 0, BACKGROUNDCAUTION);
    PlaceBitmap (BITMAP_FILE, BITMAP_ID, 0, 0, CENTERED);
    Delay (3);
    PlaceBitmap ("", BITMAP_ID, 0, 0, REMOVE);

    // 2. Display bitmap using the reveal effect.
    SetDisplayEffect (EFF_REVEAL);

    SetTitle ("Reveal effect", 0, BACKGROUNDCAUTION);
    PlaceBitmap (BITMAP_FILE, BITMAP_ID, 0, 0, CENTERED);
    Delay (3);
    PlaceBitmap ("", BITMAP_ID, 0, 0, REMOVE);

    // 3. Display bitmap using the horizontal reveal effect.
    SetDisplayEffect (EFF_HORZREVEAL);

    SetTitle ("Horizontal reveal effect", 0, BACKGROUNDCAUTION);
    PlaceBitmap (BITMAP_FILE, BITMAP_ID, 0, 0, CENTERED);
    Delay (3);
    PlaceBitmap ("", BITMAP_ID, 0, 0, REMOVE);

    // 4. Display bitmap using the horizontal stripe effect.

```

```

SetDisplayEffect (EFF_HORIZSTRIPE);

SetTitle ("Horizontal stripe effect", 0, BACKGROUNDCAPTION);
PlaceBitmap (BITMAP_FILE, BITMAP_ID, 0, 0, CENTERED);
Delay (3);
PlaceBitmap ("", BITMAP_ID, 0, 0, REMOVE);

// 5. Display bitmap using the vertical stripe effect.
SetDisplayEffect (EFF_VERTSTRIPE);

SetTitle ("Vertical stripe effect", 0, BACKGROUNDCAPTION);
PlaceBitmap (BITMAP_FILE, BITMAP_ID, 0, 0, CENTERED);
Delay (3);
PlaceBitmap ("", BITMAP_ID, 0, 0, REMOVE);

// 6. Display bitmap using the box stripe effect.
SetDisplayEffect (EFF_BOXSTRIPE);

SetTitle ("Box stripe effect", 0, BACKGROUNDCAPTION);
PlaceBitmap (BITMAP_FILE, BITMAP_ID, 0, 0, CENTERED);
Delay (3);
PlaceBitmap ("", BITMAP_ID, 0, 0, REMOVE);
Delay (1);

// 7. Clear all effects.
SetDisplayEffect (EFF_NONE);

SetTitle ("No effect", 0, BACKGROUNDCAPTION);
PlaceBitmap (BITMAP_FILE, BITMAP_ID, 0, 0, CENTERED);
Delay (3);
PlaceBitmap ("", BITMAP_ID, 0, 0, REMOVE);

Delay (1);

end;

```

## SetErrorMsg

When a disk error occurs, the **SetErrorMsg** function sets the corresponding error message that is displayed by the **EnterDiskError** function.

### Syntax

```
SetErrorMsg (nErrorID, szText);
```

## Parameters

**Table 144** ▪ SetErrorMsg Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nErrorID</b> | Specifies which error message to customize. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>• <b>ERR_BOX_BADPATH</b>—This message appears when <b>EnterDiskError</b> detects a bad path entered by the user.</li> <li>• <b>ERR_BOX_BADTAGFILE</b>—This message appears when <b>EnterDiskError</b> detects the specified tag file does not exist on the disk.</li> <li>• <b>ERR_BOX_DISKID</b>—This message appears when <b>EnterDiskError</b> detects the drive specified by the user does not exist.</li> </ul> |
| <b>szText</b>   | Specifies the error message to display in the message box.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Return Values

**Table 145** ▪ SetErrorMsg Return Values

| Return Value  | Description                                                         |
|---------------|---------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully changed the error message. |
| <b>&lt; 0</b> | Indicates that the function was unable to change the error message. |

## SetErrorMsg Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SetErrorMsg function.
*
* This script customizes the error messages displayed after a
* call to EnterDisk if the next disk in a set of setup disks
* is not ready in the specified drive.
*
\*-----*/

// Define the text messages for EnterDisk errors.
#define MSG_DRIVE_DOOR "The drive door is open."
#define MSG_BAD_PATH   "The path does not exist."
#define MSG_BAD_TAG    "Bad tag file."
```

```

#define MSG_BAD_DRIVE  "The specified drive does not exist."

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_SetErrorMsg(HWND);

function ExFn_SetErrorMsg(hMSI)
begin

    // Set the messages for the error boxes of the EnterDisk function.
    SetErrorMsg (ERR_BOX_DRIVEOPEN, MSG_DRIVE_DOOR);
    SetErrorMsg (ERR_BOX_BADPATH, MSG_BAD_PATH  );
    SetErrorMsg (ERR_BOX_BADTAGFILE, MSG_BAD_TAG);
    SetErrorMsg (ERR_BOX_DISKID, MSG_BAD_DRIVE);

    // Prompt the user to specify a disk.
    EnterDisk ("Please enter the 'Examples' disk:", "Example.exe");

end;

```

## SetErrorTitle

When a disk error occurs, the **SetErrorTitle** function sets the title bar for the error message that is displayed by the **EnterDiskError** function.

### Syntax

```
SetErrorTitle (nErrorID, szText);
```

## Parameters

**Table 146** ▪ SetErrorTitle Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nErrorID</b> | Specifies the error message box whose title you want to customize. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>ERR_BOX_BADPATH</b>—This message appears when <b>EnterDiskError</b> detects a bad path.</li> <li>● <b>ERR_BOX_BADTAGFILE</b>—This message box appears when <b>EnterDiskError</b> detects that the specified tag file does not exist on the disk.</li> <li>● <b>ERR_BOX_DISKID</b>—This message box appears when <b>EnterDiskError</b> detects that the specified drive does not exist.</li> </ul> |
| <b>szText</b>   | Specifies the title to display in the error message box.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Return Values

**Table 147** ▪ SetErrorTitle Return Values

| Return Value  | Description                                                                 |
|---------------|-----------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully changes the text in the title bar. |
| <b>&lt; 0</b> | Indicates that the function was unable to change the text in the title bar. |

## SetErrorTitle Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the SetErrorTitle function.
*
* This script customizes the title text for the message box
* displayed after a call to EnterDisk if the next disk in set
* of setup disks is not ready in the specified drive.
*
\*-----*/

// Define the message box title text for EnterDisk errors.
#define MSG_DRIVE_DOOR "Drive door is open."
#define MSG_BAD_PATH   "Path not found."
#define MSG_BAD_TAG    "Bad tag file."
```

```

#define MSG_BAD_DRIVE "Drive not found."

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SetErrorTitle(HWND);

function ExFn_SetErrorTitle(hMSI)
    STRING szText;
    NUMBER nErrorID;
begin

    // Set the message box title for each error that can
    // occur after a call to EnterDisk.
    SetErrorTitle (ERR_BOX_DRIVEOPEN, MSG_DRIVE_DOOR);
    SetErrorTitle (ERR_BOX_DISKID, MSG_BAD_DRIVE);
    SetErrorTitle (ERR_BOX_BADTAGFILE, MSG_BAD_TAG);
    SetErrorTitle (ERR_BOX_BADPATH, MSG_BAD_PATH);

    // Make drive A: the default.

    // Prompt the user to specify a disk.
    EnterDisk ("Please enter the 'Examples' disk:", "Example.exe");

end;

```

## SetExtendedErrInfo

**Project** ▪ This information applies to InstallScript projects.

The **SetExtendedErrInfo** function sets error information, which can be retrieved by **GetExtendedErrInfo**.

### Syntax

```
SetExtendedErrInfo ( szScriptFile, nLineNumber, nError );
```

## Parameters

**Table 148** ▪ SetExtendedErrInfo Parameters

| Parameter           | Description                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szScriptFile</b> | Specifies the script file in which the error occurred. To specify the current script file (that is, the script file that contains the call to SetExtendedErrInfo), pass the reserved identifier <code>__FILE__</code> . |
| <b>nLineNumber</b>  | Specifies the line number in which the error occurred. To specify the current line number (that is, the line number of the call to SetExtendedErrInfo), pass the reserved identifier <code>__LINE__</code> .            |
| <b>nError</b>       | Specifies the error code for the error.                                                                                                                                                                                 |

## Return Values

**Table 149** ▪ SetExtendedErrInfo Return Values

| Return Value               | Description                                          |
|----------------------------|------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully set the error information. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to set the error information.    |

# SetFileInfo

The **SetFileInfo** function sets the modify date or time stamp of an existing file or changes the file's attributes. To change both a file's date and time you must call SetFileInfo twice, once to change the date and once to change the time. However, you can set multiple file attributes with a single call to SetFileInfo by combining constants in nAttribute with the OR ( | ) operator.

**Note** ▪ You can also use this function to change a folder's attribute. For example, you can use this function to create a hidden folder.

## Syntax

```
SetFileInfo ( szPathFile, nType, nAttribute, szValue );
```

## Parameters

**Table 150** ▪ SetFileInfo Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPathFile</b> | Specifies the fully qualified name of the file or folder whose date, time, or attributes you want to change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>nType</b>      | <p>Specifies the file characteristic to change. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FILE_ATTRIBUTE</b>—Indicates that one or more of the file's attributes will be changed.</li> <li>● <b>FILE_DATE</b>—Indicates that the file's date stamp will be changed.</li> <li>● <b>FILE_TIME</b>—Indicates the file's time stamp will be changed.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>nAttribute</b> | <p>Specifies the file attribute when nType is FILE_ATTRIBUTE. (When nType is FILE_DATE or FILE_TIME, pass 0 in this parameter.) To specify more than one file attribute, combine one or more of the following predefined constants with the OR ( ) operator:</p> <ul style="list-style-type: none"> <li>● <b>FILE_ATTR_ARCHIVED</b>—Sets the archive attribute.</li> <li>● <b>FILE_ATTR_HIDDEN</b>—Sets the hidden attribute.</li> <li>● <b>FILE_ATTR_READONLY</b>—Sets the read-only attribute.</li> <li>● <b>FILE_ATTR_SYSTEM</b>—Sets the system attribute.</li> <li>● <b>FILE_ATTR_NORMAL</b>—When this constant is specified alone, all file attributes are cleared. When the OR operator is used to combine this constant with other file attribute constants, those attributes not included in the OR expression are cleared.</li> </ul> |
| <b>szValue</b>    | <p>Specifies one of the following, depending on the value you passed in nType:</p> <ul style="list-style-type: none"> <li>● <b>FILE_DATE</b>—Specifies a date in the format YYYY/MM/DD or YYYY\MM\DD. That date must not be earlier than "1980/01/01". When using backslashes as delimiters, remember that a backslash is inserted into a string as an escape sequence, for example, "1980\\01\\01".</li> <li>● <b>FILE_TIME</b>—Specifies a time in the format HH:MM:SS, using a 24-hour clock format; note that the seconds must be a multiple of 2.</li> <li>● <b>FILE_ATTRIBUTE</b>—Pass a null string ("") in this parameter.</li> </ul>                                                                                                                                                                                                   |

## Return Values

**Table 151** ▪ SetFileInfo Return Values

| Return Value | Description                                                                                     |
|--------------|-------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully set the file's date stamp, time stamp, or attributes.  |
| < 0          | Indicates that the function was unable to set the file's date stamp, time stamp, or attributes. |

## SetFileInfo Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SetFileInfo function.
 *
 * SetFileInfo is called to set a file's date, time, and
 * attributes.
 *
 * Note: Before running this script, create a file called
 *       ISExempl.txt in the root of drive C.
 *
\*-----*/

#define EXAMPLE_FILE "C:\\ISExempl.txt"

#define TITLE_TEXT   "SetFileInfo Example"

#define NEW_FILE_DATE "2003/09/12"
#define NEW_FILE_TIME "18:30:00"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_SetFileInfo(HWND);

function ExFn_SetFileInfo(hMSI)
    LIST listID;
begin

    // Create a list to hold messages.
    listID = ListCreate (STRINGLIST);

    // If an error occurred, report it; then terminate.
    if (listID = LIST_NULL) then

```

```

        MessageBox ("Unable to create list required for this example.", SEVERE);
        abort;
    endif;

    // Set the file's date.
    if (SetFileInfo (EXAMPLE_FILE, FILE_DATE, 0, NEW_FILE_DATE) < 0) then
        ListAddString (listID, "Unable to change the file\'s date.", AFTER);

    else
        ListAddString (listID, "File\'s date changed to" + NEW_FILE_DATE + ".",
AFTER);

    endif;

    // Set the file's time.
    if (SetFileInfo (EXAMPLE_FILE, FILE_TIME, 0, NEW_FILE_TIME) < 0) then
        ListAddString (listID, "Unable to change the file\'s time.", AFTER);

    else
        ListAddString (listID, "File\'s date changed to" + NEW_FILE_TIME + ".",
AFTER);

    endif;

    // Clear the file's attributes.
    if (SetFileInfo (EXAMPLE_FILE, FILE_ATTRIBUTE, FILE_ATTR_NORMAL, "") < 0)
then
        ListAddString (listID, "Unable to clear file attributes.", AFTER);

    else
        ListAddString (listID, "File attributes cleared.", AFTER);

    endif;

    // Report the results.
    SdShowInfoList (TITLE_TEXT, "Changes to " + EXAMPLE_FILE, listID);

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## SetFont

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SetFont** function sets the font and style when displaying text strings. You can use standard Windows fonts with this function.

## Syntax

```
SetFont ( nItemID, nFontStyle, szFontName );
```

## Parameters

**Table 152** ▪ SetFont Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nItemID</b>    | Specifies the item whose font and font style is to be set. Pass the following predefined constant in this parameter: <ul style="list-style-type: none"> <li><b>FONT_TITLE</b>—Specifies the main title of the setup procedure, which is displayed in the top left corner of the setup window.</li> </ul>                                                                                                                                                                      |
| <b>nFontStyle</b> | Specifies font styles. Pass one or more of the following predefined constants in this parameter. All but STYLE_NORMAL can be bitwise ORed to specify multiple styles. <ul style="list-style-type: none"> <li><b>STYLE_NORMAL</b>—No bold, italic, or shadow (cannot be ORed)</li> <li><b>STYLE_BOLD</b>—Bold text.</li> <li><b>STYLE_ITALIC</b>—Italic text.</li> <li><b>STYLE_SHADOW</b>—Text with shadow drawn.</li> <li><b>STYLE_UNDERLINE</b>—Underlined text.</li> </ul> |
| <b>szFontName</b> | Specifies the name of an available Windows font. Valid font names include Courier, Helv, Helvetica, Modern, Roman, Script, Terminal, Times, and TmsRmn. If the specified font is not found with the styles specified, Arial is used.                                                                                                                                                                                                                                          |

## Return Values

**Table 153** ▪ SetFont Return Values

| Return Value  | Description                                             |
|---------------|---------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully set the font.  |
| <b>&lt; 0</b> | Indicates that the function was unable to set the font. |

## SetFont Example

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SetFont function.
 *
```

```

* In this script, three different titles are displayed in
* the setup's main window; each title remains on the
* screen for three seconds. The titles are displayed by
* calls to SetTitle, which also sets the type size and
* color. To control the font and font style of the titles,
* the script calls SetFont before each call to SetTitle.
*
*           Font           Size   Style           Color
*
* Title 1   Times New Roman   36    Normal         Red
* Title 2   Courier New       48    Italic          Yellow
* Title 3   Arial             60    Bold, Shadow   Blue
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SetFont(HWND);

function ExFn_SetFont(hMSI)
begin

    Enable ( BACKGROUND );

    // Title 1: Times Roman, 36pt, Normal, Red.
    if (SetFont (FONT_TITLE, STYLE_NORMAL, "Times New Roman") < 0) then
        MessageBox ("SetFont failed.", SEVERE);
    endif;

    SetTitle ("SetFont Example 1", 36, RGB(255, 0, 0));
    Delay (3);

    // Title 2: Courier New, 48pt, Italic, Yellow.
    if (SetFont (FONT_TITLE, STYLE_ITALIC, "Courier New") < 0) then
        MessageBox ("SetFont failed.", SEVERE);
    endif;

    SetTitle ("SetFont Example 2", 48, RGB(255, 255, 0));
    Delay (3);

    // Title 3: Arial, 60pt, Bold, Shadow, Blue.
    if (SetFont (FONT_TITLE, STYLE_BOLD | STYLE_SHADOW, "Arial") < 0) then
        MessageBox ("SetFont failed.", SEVERE);
    endif;

    SetTitle ("SetFont Example 3", 60, RGB(0, 0, 255));
    Delay (3);

end;

```

# SetInstallationInfo

The **SetInstallationInfo** function sets the values of the system variables IFX\_COMPANY\_NAME, IFX\_PRODUCT\_NAME, IFX\_PRODUCT\_VERSION, and IFX\_PRODUCT\_KEY. SetInstallationInfo specifies this information for use by CreateInstallationInfo, which in an event-based script is called in the default OnShowUI event handler code to create an application information key and a per application paths key for the program you are installing.

SetInstallationInfo is a special registry-related function, designed to work with certain predefined registry keys. For more information on special registry-related functions, see [Special Registry-Related Functions](#).

## Syntax

```
SetInstallationInfo ( szCompany, szProduct, szVersion, szProductKey );
```

## Parameters

**Table 154** • SetInstallationInfo Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szCompany</b>    | Specifies the company name. CreateInstallationInfo uses szCompany to create a \<company> key under the HKEY_LOCAL_MACHINE\Software key in the registry.                                                                                                                                                                                                                                                                                                                                      |
| <b>szProduct</b>    | Specifies the name of the product to be installed. CreateInstallationInfo uses szProduct to create a \<product> key under the HKEY_LOCAL_MACHINE\Software\<company> key in the registry. The value in szProduct is also inserted into the first paragraph of message text in the Welcome dialog.                                                                                                                                                                                             |
| <b>szVersion</b>    | Specifies the version number of the product. CreateInstallationInfo uses szVersion to create a \<version> key under the HKEY_LOCAL_MACHINE\Software\<company>\<product> key in the registry. Together, the \<company> key (szCompany), the \<product> key (szProduct), and the \<version> key (szVersion) are referred to as the application information key. The application information key is created immediately upon calling CreateInstallationInfo.                                    |
| <b>szProductKey</b> | Specifies the name of the application's main executable file. If your product uses several executables, specify the executable that best represents the product. CreateInstallationInfo uses szProductKey to create a per application paths key under the key HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\App Paths. The per application paths key is not actually created in the registry until you call RegDBSetItem to create a value name and value pair under the key. |

## Return Values

This function always returns 0.

# SetObjectPermissions

The **SetObjectPermissions** function is used to set permissions for a file, a folder, or a registry key. The file, folder, or registry key can be installed as part of your installation, or it can be already present on the target system.

## Syntax

```
SetObjectPermissions (byval string szObject, byval number nType, byval string szDomain, byval string szUser, byval number nPermissions, byval number nOptions);
```

## Parameters

**Table 155** ▪ SetObjectPermissions Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szObject</b> | <p>Specify the object (file, folder, or registry key) for which you want to set permissions.</p> <p>For files and folders, specify the full path.</p> <p>For registry keys, use one of the following in the path:</p> <ul style="list-style-type: none"> <li>● <b>CLASSES_ROOT</b>—This indicates the HKEY_CLASSES_ROOT hive.</li> <li>● <b>CURRENT_USER</b>—This indicates the HKEY_CURRENT_USER hive.</li> <li>● <b>MACHINE</b>—This indicates the HKEY_LOCAL_MACHINE hive.</li> <li>● <b>USERS</b>—This indicates the HKEY_USERS hive.</li> </ul> <p>The following example set permissions for a key in HKEY_LOCAL_MACHINE:</p> <pre>SetObjectPermissions("MACHINE\\Software\\MyProduct\\Example", IS_PERMISSIONS_TYPE_REGISTRY, "", "Users", KEY_CREATE_SUB_KEY, IS_PERMISSIONS_OPTION_DENY_ACCESS);</pre> |
| <b>nType</b>    | <p>Indicate the type of object that is being passed through the szObject parameter. Valid options are:</p> <ul style="list-style-type: none"> <li>● <b>IS_PERMISSIONS_TYPE_FILE</b>—szObject is a file.</li> <li>● <b>IS_PERMISSIONS_TYPE_FOLDER</b>—szObject is a folder.</li> <li>● <b>IS_PERMISSIONS_TYPE_REGISTRY</b>—szObject is a registry key.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>szDomain</b> | <p>Specify the domain name of the user for which permissions are being set.</p> <p>To use the local machine as the domain, pass an empty string ("") for this parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Table 155** ▪ SetObjectPermissions Parameters (cont.)

| Parameter     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szUser</b> | <p>Specify the name of the user for which permissions are being set. Available options are:</p> <ul style="list-style-type: none"><li>• Administrators</li><li>• Authenticated Users</li><li>• Creator Owner</li><li>• Everyone</li><li>• Guests</li><li>• Interactive</li><li>• IUSR</li><li>• Local Service</li><li>• Local System</li><li>• Network Service</li><li>• Power Users</li><li>• Remote Desktop Users</li><li>• Users</li></ul> <p>The user can be one that is being created during the installation, or one that already exists on the target system at run time.</p> |

**Table 155** ▪ SetObjectPermissions Parameters (cont.)

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nPermissions</b> | <p>To specify the permissions that are to be applied to the object for the specified user, pass one of the following predefined constants in this parameter. You can combine these constants by using the bitwise OR operator (   ).</p> <p>Available options are:</p> <ul style="list-style-type: none"> <li>• DELETE</li> <li>• GENERIC_ALL</li> <li>• GENERIC_EXECUTE</li> <li>• GENERIC_WRITE</li> <li>• GENERIC_READ</li> <li>• READ_CONTROL</li> <li>• STANDARD_RIGHTS_ALL</li> <li>• STANDARD_RIGHTS_EXECUTE</li> <li>• STANDARD_RIGHTS_READ</li> <li>• STANDARD_RIGHTS_REQUIRED</li> <li>• STANDARD_RIGHTS_WRITE</li> <li>• SYNCHRONIZE</li> <li>• WRITE_DAC</li> <li>• WRITE_OWNER</li> </ul> <p>The following options are applicable to files and folders:</p> <ul style="list-style-type: none"> <li>• FILE_LIST_DIRECTORY (for folders)</li> <li>• FILE_READ_DATA (for files)</li> <li>• FILE_WRITE_DATA (for files)</li> <li>• FILE_ADD_FILE (for folders)</li> <li>• FILE_APPEND_DATA (for files)</li> <li>• FILE_ADD_SUBDIRECTORY (for folders)</li> <li>• FILE_READ_EA (for files and folders)</li> <li>• FILE_WRITE_EA (for files and folders)</li> <li>• FILE_EXECUTE (for files)</li> <li>• FILE_TRAVERSE (for folders)</li> <li>• FILE_DELETE_CHILD (for folders)</li> <li>• FILE_READ_ATTRIBUTES (for files and folders)</li> <li>• FILE_WRITE_ATTRIBUTES (for files and folders)</li> <li>• FILE_ALL_ACCESS</li> </ul> |

**Table 155** ▪ SetObjectPermissions Parameters (cont.)

| Parameter                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nPermissions (cont.)</b> | <p>The following options are applicable to registry keys:</p> <ul style="list-style-type: none"> <li>● KEY_QUERY_VALUE</li> <li>● KEY_SET_VALUE</li> <li>● KEY_CREATE_SUB_KEY</li> <li>● KEY_ENUMERATE_SUB_KEYS</li> <li>● KEY_NOTIFY</li> <li>● KEY_CREATE_LINK</li> </ul> <p>For information on each value, see “Registry Key Security and Access Rights,” “File Security and Access Rights,” and “Registry Key Security and Access Rights” in the MSDN Library.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>nOptions</b>             | <p>Pass one or more of the following predefined constants in this parameter.</p> <ul style="list-style-type: none"> <li>● <b>IS_PERMISSIONS_OPTION_64BIT_OBJECT</b>—The set of permissions that are specified in nPermissions should be set for a 64-bit key, regardless of whether the REGDB_OPTION_WOW64_64KEY option is enabled. Note that the IS_PERMISSIONS_OPTION_64BIT_OBJECT constant should not be passed on 32-bit target systems. In addition, this constant does not affect permissions for files or folders.</li> <li>● <b>IS_PERMISSIONS_OPTION_DENY_ACCESS</b>—The set of permissions that are specified in nPermissions should be denied.</li> <li>● <b>IS_PERMISSIONS_OPTION_NO_APPLYDOWN</b>—The permissions should be applied to only the specified object; they should not be propagated to any child objects.</li> <li>● <b>IS_PERMISSIONS_OPTION_ALLOW_ACCESS</b>—The set of permissions that are specified in nPermissions should allow access.</li> </ul> <p>You can combine more than one constant by using the bitwise OR operator (   ). The IS_PERMISSIONS_OPTION_DENY_ACCESS and IS_PERMISSIONS_OPTION_ALLOW_ACCESS constants should not be combined because they are mutually exclusive; if you specify both of these options for nOptions, permissions are denied.</p> |

## Return Values

**Table 156** ▪ SetObjectPermissions Return Values

| Return Value            | Description                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>    | The function successfully set the permissions.                                                                                          |
| <b>!= ISERR_SUCCESS</b> | The function could not set the permissions. The return value is a Win32 error. For documentation on Win32 errors, see the MSDN Library. |

## Additional Information

**SetObjectPermissions** attempts to set permissions on a 64-bit key if the REGDB\_OPTION\_WOW64\_64KEY option is enabled.

To set permissions for files that are in the 64-bit System32 folder, file system redirection should be disabled before the **SetObjectPermissions** function is called. To disable file system redirection, use the WOW64FSREDIRECTION constant, as shown in the following code:

```
Disable (WOW64FSREDIRECTION);
```

Once the operation is done, disable file system redirection:

```
Enable(WOW64FSREDIRECTION);
```

## SetObjectPermissions Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
//-----
//
//  InstallScript Example Script
//
//  Demonstrates the SetObjectPermissions function.
//
//  This sample shows how to prevent the local administrator
//  from changing a file or any of its attributes.
//
//-----

function OnFirstUIAfter()
    STRING szTitle, szMsg1, szMsg2, szOpt1, szOpt2;
    NUMBER bvOpt1, bvOpt2;
begin

    SetObjectPermissions (TARGETDIR+"MyFile.exe",IS_PERMISSIONS_TYPE_FILE, "", "administrator",
        FILE_WRITE_DATA|FILE_APPEND_DATA|FILE_WRITE_EA|FILE_WRITE_ATTRIBUTES,
        IS_PERMISSIONS_OPTION_DENY_ACCESS);

end;
```

# SetShortcutProperty

The **SetShortcutProperty** function sets one or more shortcut properties that you want the Windows Shell to set at installation run time. For example, **SetShortcutProperty** has built-in support for enabling you to set Shell properties that control the following behavior:

- Specify whether a shortcut should be pinned to the Windows 8 Start screen.
- Specify whether end users should be able to pin a shortcut to the taskbar or Start menu on Windows 7 or later systems.
- Prevent a shortcut on the Start menu from being highlighted as newly installed on Windows 7 or later systems.

**SetShortcutProperty** also lets you set additional properties that the Windows Shell supports.

---

**Note** ▪ *The shortcut and its target must be present on the target system before **SetShortcutProperty** can be called.*

**SetShortcutProperty** does not support the configuration of Internet shortcuts.

## Syntax

```
SetShortcutProperty (szShortcutFolder, szName, szPropertyKey, szValue);
```

## Parameters

**Table 157** ▪ SetShortcutProperty Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szShortcutFolder</b> | <p>Specify the path of the shortcut whose properties you want to configure.</p> <p>To configure a shortcut that is in a specific folder, specify the fully qualified path—for example:</p> <pre>C:\ProgramData\Microsoft\Windows\Start Menu\Programs</pre> <p>If the shortcut is on the Programs menu of the Start menu, you can pass a null string ("") in this parameter.</p> <p>You can pass one of the following InstallScript system variables in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>FOLDER_DESKTOP</b>—Adds the shortcut to the desktop.</li> <li>● <b>FOLDER_STARTUP</b>—Adds the shortcut to the Startup menu.</li> <li>● <b>FOLDER_STARTMENU</b>—Adds the shortcut to the Start menu.</li> <li>● <b>FOLDER_PROGRAMS</b>—Adds the shortcut to the Start\Programs menu.</li> </ul> <p>You can also specify a path relative to a folder that is identified by an InstallScript system variable—for example:</p> <pre>FOLDER_PROGRAMS ^ "ACCESSORIES\GAMES"</pre> |
| <b>szName</b>           | Specify the name of the shortcut that you are configuring.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 157** ▪ SetShortcutProperty Parameters (cont.)

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szPropertyKey</b> | <p>Specify the property key name that you want to set. The properties that can be set are defined in <code>propkey.h</code>, which is part of the Windows SDK.</p> <p>You can pass any of the following constants for property keys that are predefined in <code>InstallScript</code>:</p> <ul style="list-style-type: none"> <li>● <b>SSP_PROPERTY_PREVENT_PINNING</b>—Do not allow the shortcut to be pinned to the Start menu or taskbar on Windows 7 or later systems. This option hides the context menu commands that enable end users to pin the shortcut to the taskbar and to the Start menu.</li> </ul> <p>You may want to prevent pinning for shortcuts that are for tools and secondary products that are part of your installation.</p> <p>To enable this property, set <code>szValue</code> to 1.</p> <ul style="list-style-type: none"> <li>● <b>SSP_PROPERTY_NO_NEW_INSTALL_HIGHLIGHT</b>—Do not highlight the shortcut as newly installed after end users install your product on Windows 7 or later systems. This has the same effect as clearing the Highlight newly installed programs check box in the Customize Start Menu dialog box for an individual item on a target system.</li> </ul> <p>You may want to use this option for shortcuts that are for tools and secondary products that are part of your installation.</p> <p>To enable this property, set <code>szValue</code> to 1.</p> <ul style="list-style-type: none"> <li>● <b>SSP_PROPERTY_NO_STARTSCREEN_PIN</b>—Do not pin the shortcut to the Start screen by default on Windows 8 target systems. If you pass this constant, the installation sets a Windows Shell property that was introduced in Windows 8.</li> </ul> <p>You may want to prevent pinning for shortcuts that are for tools and secondary products that are part of your installation.</p> <p>To enable this property, set <code>szValue</code> to 1.</p> <p>For more information on <code>SSP_PROPERTY_PREVENT_PINNING</code> and <code>SSP_PROPERTY_NO_STARTSCREEN_PIN</code>, see the <a href="#">Additional Information section</a>.</p> |
| <b>szValue</b>       | <p>Specify the value (represented as a string) of the property that you are setting. For information on the value to use with a given property, see <code>propkey.h</code>, which is part of the Windows SDK.</p> <p>The <code>InstallScript</code> engine converts the string value into the appropriate data type that corresponds with the property that is specified in <code>szPropertyKey</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Return Values

**Table 158:**

| Return Value               | Description                                                                                                                                                                                                                                     |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully set the shortcut property.                                                                                                                                                                             |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to set the shortcut property.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891(0x80070005)—by calling <a href="#">FormatMessage</a> . |

## Additional Information

Note the following details about two of the nFlag constants.

### SSP\_PROPERTY\_PREVENT\_PINNING

If you configure the shortcut to prevent pinning to the taskbar and the Start menu, the target of the shortcut is ineligible for inclusion in the most frequently used list on the Start menu.

Shortcuts that contain certain strings cannot be pinned to the taskbar or the Start menu, and they cannot be displayed in the most frequently used list. Examples are:

- Documentation
- Help
- Install
- Remove
- Setup
- Support

### SSP\_PROPERTY\_NO\_STARTSCREEN\_PIN

Note that Windows 8 maintains information about shortcut pinning to the Start screen after a shortcut is removed by uninstalling the application. Therefore, the SSP\_PROPERTY\_NO\_STARTSCREEN\_PIN constant has no effect on the target system if the shortcut has already been installed on it. Thus, when you are testing this functionality, ensure that you test on a clean machine—one on which this shortcut and its target have never been installed.

## SetShortcutProperty Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
```

```

* Demonstrates the SetShortcutProperty function.
*
* This example sets a Shell property for a shortcut. The
* property hides the context menu commands that enable
* end users to pin the shortcut to the taskbar and to the
* Start menu.
*
* Note: In order for this script to run correctly, add an
* executable file to your project, and in the Shortcuts view,
* create a shortcut called My Shortcut. The target of the
* shortcut should be the executable file that you added to
* your project. The location of the shortcut should be the
* desktop.
*
\*-----*/

function OnFirstUIAfter()
    STRING szName, szValue;
begin

    // Set up parameters for the SetShortcutProperty call.
    szName = "My Shortcut";
    szValue = "1";

    // Set the shortcut property that prevents pinning to the taskbar and the Start menu.
    if (SetShortcutProperty (FOLDER_DESKTOP, szName, SSP_PROPERTY_PREVENT_PINNING,
        szValue) < 0) then
        MessageBox ("SetShortcutProperty failed", SEVERE);
    else
        sprintfBox (INFORMATION, "SetShortcutProperty", "%s configured successfully.",
            szName);
    endif;

end;

```

## SetStatus

**Project** ▪ This information applies to InstallScript projects.

The **SetStatus** function is called in an object script to set the object's Status.Number and Status.Description properties. To set the object's other status properties, call SetStatusEx.

### Syntax

```
SetStatus ( nNumber, szDescription );
```

## Parameters

**Table 159** ▪ SetStatus Parameters

| Parameter            | Description                                |
|----------------------|--------------------------------------------|
| <b>nNumber</b>       | Specifies the value of Status.Number.      |
| <b>szDescription</b> | Specifies the value of Status.Description. |

## Return Values

**Table 160** ▪ SetStatus Return Values

| Return Value               | Description                                          |
|----------------------------|------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully set the status properties. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to set the status properties.    |

# SetStatusEx

**Project** ▪ This information applies to InstallScript projects.

The **SetStatusEx** function is called in an object script to set the object's status properties.

## Syntax

```
SetStatusEx ( nNumber, szDescription, szSource, szScriptFile, nScriptLine, nScriptError );
```

## Parameters

**Table 161** ▪ SetStatusEx Parameters

| Parameter            | Description                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nNumber</b>       | Specifies the value of Status.Number.                                                                                                                                                                 |
| <b>szDescription</b> | Specifies the value of Status.Description.                                                                                                                                                            |
| <b>szSource</b>      | Specifies the value of Status.szSource.                                                                                                                                                               |
| <b>szScriptFile</b>  | Specifies the value of Status.szScriptFile. To specify the current script file (that is, the script file that contains the call to SetStatusEx), pass the reserved identifier <code>__FILE__</code> . |
| <b>nScriptLine</b>   | Specifies the value of Status.nScriptLine. To specify the current line number (that is, the line number of the call to SetStatusEx), pass the reserved identifier <code>__LINE__</code> .             |
| <b>nScriptError</b>  | Specifies the value of Status.nScriptError.                                                                                                                                                           |

## Return Values

**Table 162** ▪ SetStatusEx Return Values

| Return Value               | Description                                          |
|----------------------------|------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully set the status properties. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to set the status properties.    |

# SetStatusExStaticText

The **SetStatusExStaticText** function sets the static text displayed in the STATUSEX dialog above the status text. The events OnFirstUIBefore, OnMaintUIBefore, and OnUpdateUIBefore automatically call this function to set the status text appropriately.

## Syntax

```
SetStatusExStaticText ( szString);
```

## Parameters

**Table 163** ▪ SetStatusExStaticText Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szString</b> | <p>The text to be set as the static text. The following standard strings are available using the SdLoadString function:</p> <ul style="list-style-type: none"> <li>• <b>IDS_IFX_STATUSEX_STATICTEXT_FIRSTUI</b>—The InstallShield Wizard is installing %P.</li> <li>• <b>IDS_IFX_STATUSEX_STATICTEXT_MAINTUI_MODIFY</b>—The InstallShield Wizard is modifying %P.</li> <li>• <b>IDS_IFX_STATUSEX_STATICTEXT_MAINTUI_REPAIR</b>—The InstallShield Wizard is repairing %P.</li> <li>• <b>IDS_IFX_STATUSEX_STATICTEXT_MAINTUI_REMOVEALL</b>—The InstallShield Wizard is removing %P.</li> <li>• <b>IDS_IFX_STATUSEX_STATICTEXT_UPDATEUI</b>—The InstallShield Wizard is updated %VI of %P to version %VS.</li> </ul> <p></p> <p><b>Note</b> ▪ The status dialog supports the text substitution, %P, but does not support any other text substitutions such as %VI or %VS. If you are setting the static text to a string with any other text substitution than %P, you must call the SdSubstituteProductInfo function to update these text substitutions to the correct value before calling SetStatusExStaticText.</p> |

## Return Values

**Table 164** ▪ SetStatusExStaticText Return Values

| Return Value              | Description                                     |
|---------------------------|-------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | Indicates that the function was successful.     |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function was not successful. |

# SetStatusWindow

The **SetStatusWindow** function sets an initial or current value for the percentage complete indicator of the progress indicator (status bar) and specifies the current message to display on the top line of the progress indicator.

Setups that install files using the FeatureMoveData function must call SetStatusWindow before calling FeatureMoveData in order to set the percentage complete indicator to 0% and clear the top line of the indicator. No additional calls to SetStatusWindow are required. The 'Status Text' string for each feature is displayed on the top line of the status bar automatically while the files of the feature are being installed.

Before calling FeatureMoveData, your setup should also call the StatusUpdate function to enable automatic updating of the percentage complete indicator during file transfer. To enable the display of the name and path of the file being installed on the second line of the status bar, call Enable with the INDVFILESTATUS parameter before calling FeatureMoveData. After these calls, the percentage complete indicator is updated smoothly during file transfer and the names of individual files are displayed as they are transferred when the FeatureMoveData function is called.

Setups that install files using the CopyFile or XCopyFile functions may need to make multiple calls to SetStatusWindow in order to change the message on the top line of the indicator between successive calls to CopyFile or XCopyFile. StatusUpdate and Enable (with the parameter INDVFILESTATUS) work normally with CopyFile and XCopyFile. It is not necessary to call SetStatusWindow to change the percentage complete indicator between successive calls to CopyFile or XCopyFile if you have called StatusUpdate to enable automatic updating.

## Syntax

```
SetStatusWindow ( nPercent, szString );
```

## Parameters

**Table 165** ▪ SetStatusWindow Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nPercent</b> | Specifies a value between 0 and 100 that represents the percentage to be displayed by the percentage complete indicator. To reset the indicator before calling FeatureMoveData, specify 0. To change the message displayed on the top line of the status bar without changing the percentage complete indicator, specify -1 in this parameter. |
| <b>szString</b> | Specifies a string to display on the top line of the status bar. Note that if a 'DisplayText' parameter has been specified for this feature (in the IDE), that string automatically overwrites any text specified in this parameter when FeatureMoveData is called.                                                                            |

## Return Values

This function does not return a value.

## SetStatusWindow Example

This function cannot be used in a Basic MSI installation.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SetStatusWindow function.
 *
 * SetStatusWindow is called to set the progress bar and
 * to display text in the progress indicator.
 *
 * Note: Before running this script, create the directories
 *       and file referenced by the preprocessor constants.
 *
\*-----*/

#define SOURCE_DIR "C:\\Source"
#define TARGET_DIR "C:\\Target"
#define TARGET_FILE "ISExempl.txt"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SetStatusWindow(HWND);

function ExFn_SetStatusWindow(hMSI)
begin
    // Enable progress indicator.
    Enable (STATUS);

    // Set the progress bar to 33% and display a message.
    SetStatusWindow (33, "Now copying file...");

    // Delay for two seconds to ensure the window is displayed correctly.
    Delay (2);

    // Copy the file in the source directory to the target directory
    CopyFile (SOURCE_DIR ^ TARGET_FILE, TARGET_DIR ^ TARGET_FILE);

    // Set the progress bar to 66% and display a message.
    SetStatusWindow (66, "Now deleting file...");
    Delay (2);

    // Delete copied file in the Target directory.
    DeleteFile (TARGET_FILE);

    // Set the percent indicator to 100% and display a message.
    SetStatusWindow (100, "SetStatusWindow example completed.");
    Delay (2);

end;

```

# SetTitle

---

**Project** ▪ *This information does not apply to Basic MSI projects.*

The **SetTitle** function displays a title either in the main window's title bar or inside the main window, depending on the value of nColor.

---

**Tip** ▪ *To set the background color of your setup, call SetColor.*

*To set the font and font style of the title displayed inside the background window, call SetFont.*

## Syntax

```
SetTitle ( szTitle, nPointSize, nColor );
```

## Parameters

**Table 166** ▪ SetTitle Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | <p>Specifies a title to appear either in the main window's title bar or inside the main window. If the title is to appear in the window's title bar, you must specify the predefined constant BACKGROUNDCAPTION in the third parameter. A title bar title that does not fit the available space will be displayed truncated on the right and terminated with ellipses. The default title bar title is "Setup".</p>  <p><b>Note</b> ▪ The BACKGROUNDCAPTION option is supported for backward compatibility only. The recommended method for setting the main window's title bar is to set the value of the system variable IFX_SETUP_TITLE.</p> <p>When a color value is passed in the third parameter, the title is displayed left aligned at the top of the main window. Titles that are too wide for the main window will be displayed truncated on the right. To create a title that occupies more than one line, embed newline characters where you want the line to break.</p> |
| <b>nPointSize</b> | <p>Specifies the size, in points, of a title to be displayed in the main window. The suggested size is 24 points. Note that this parameter is ignored when the third parameter is BACKGROUNDCAPTION.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 166 ▪ SetTitle Parameters (cont.)

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nColor    | <p>Specifies either a color or the predefined constant BACKGROUNDCAPTION.</p> <div></div> <p><b>Note</b> ▪ Calling SetTitle with the nColor set to BACKGROUNDCAPTION has no effect on setups that do not run in window mode. To run your setup in a standard window, you must first call Enable with the parameter DEFWINDOWMODE or FULLWINDOWMODE and then display the window by calling Enable with the parameter BACKGROUND.</p> <ul style="list-style-type: none"><li>• To indicate that the value of szTitle should be displayed in the title bar of the main window, pass the predefined constant BACKGROUNDCAPTION in this parameter. When you specify BACKGROUNDCAPTION, nPointSize is ignored; the color and size of the title bar title are determined by the end user's system settings. Note that this option has no effect on setups that do not run in window mode.</li><li>• To indicate that the value of szTitle should be displayed inside the setup window, specify a color for that title by passing one of the following constants (whose corresponding RGB values are given in parentheses) or calling the RGB function to indicate a particular custom color.</li></ul> <p><b>BLACK</b>—(0, 0, 0)</p> <p><b>BLUE</b>—(0, 0, 255)</p> <p><b>GREEN</b>—(0, 255, 0)</p> <p><b>MAGENTA</b>—(255, 0, 127)</p> <p><b>RED</b>—(255, 0, 0)</p> <p><b>WHITE</b>—(255, 255, 255)</p> <p><b>YELLOW</b>—(255, 255, 0)</p> <div></div> <p><b>Note</b> ▪ Magenta is not part of the standard Windows 16-color palette.</p> |

## Return Values

**Table 167** ▪ SetTitle Return Values

| Return Value | Description                                                           |
|--------------|-----------------------------------------------------------------------|
| 0            | Indicates that the function successfully set the title of the setup.  |
| < 0          | Indicates that the function was unable to set the title of the setup. |

## SetTitle Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SetTitle function.
 *
 * This script displays a title in yellow, 24-point type.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SetTitle(HWND);

function ExFn_SetTitle(hMSI)
begin

    // Make the background window a standard maximized window.
    Enable (FULLWINDOWMODE);

    // Set the background color to blue.
    SetColor (BACKGROUND, BK_BLUE);

    // Display a title in the window. The newline character
    // in the title string forces "Example" to the next line.
    SetTitle ("SetTitle\nExample", 24, YELLOW);

    // Display the background window
    Enable (BACKGROUND);

    // Leave the window open for 3 seconds.
    Delay (3);

end;

```

## SetUpdateStatus

The **SetUpdateStatus** function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPL.

## Syntax

```
void SetUpdateStatus( BOOL );
```

# SetUpdateStatusReboot

The **SetUpdateStatusReboot** function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPL.

## Syntax

```
void SetUpdateStatusReboot( BOOL );
```

# SetupType

**Project** - This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SetupType** function displays a dialog that enables the end user to select one of the three standard setup types: Typical, Compact, or Custom. These setup options are displayed with standard description text. If you want to add other setup types or change the displayed setup type names or descriptions, call [SdSetupTypeEx](#) instead.

**Caution** - If an end user returns to the Setup Type dialog after using a feature dialog to select and deselect features associated with the selected setup type, those choices are lost. This occurs because the SetupType function automatically resets the default feature selections for the selected setup type each time it is called.

## Syntax

```
SetupType ( szTitle, szMsg, szReserved, nType, nReserved );
```

## Parameters

**Table 168** ▪ SetupType Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of this dialog. To display the default title Setup Type, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                             |
| <b>szMsg</b>      | Specifies the message you want to display at the top of the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                                                                                 |
| <b>szReserved</b> | Pass a null string ("") in this parameter—no other value is allowed.                                                                                                                                                                                                                                                                                                                |
| <b>nType</b>      | Specifies the default setup type when the dialog is opened. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>TYPICAL</b>—Defines the default setup type as Typical.</li> <li>● <b>COMPACT</b>—Defines the default setup type as Compact.</li> <li>● <b>CUSTOM</b>—Defines the default setup type as Custom.</li> </ul> |
| <b>nReserved</b>  | Pass zero in this parameter. No other value is allowed.                                                                                                                                                                                                                                                                                                                             |

## Return Values

**Table 169** ▪ SetupType Return Values

| Return Value         | Description                                                  |
|----------------------|--------------------------------------------------------------|
| <b>TYPICAL (301)</b> | Indicates that the end user selected the Typical setup type. |
| <b>COMPACT (302)</b> | Indicates that the end user selected the Compact setup type. |
| <b>CUSTOM (303)</b>  | Indicates that the end user selected the Custom setup type.  |
| <b>BACK (12)</b>     | Indicates that the end user clicked the Back button.         |

## Additional Information

- In an InstallScript project, if you do not display a setup type dialog, your script must do one of the following:
  - Select a setup type.
  - Call a feature selection dialog function such as SdFeatureTree.
  - Directly select features.
- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SetupType Example

**Project** - This information applies to the following project types:

- InstallScript
- InstallScript MSI

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SetupType function.
 *
 * Comments: To run this example script, create a project (or
 *            insert into a project) with several features and
 *            subfeatures with components containing files.
 *            This example includes setup of uninstallation
 *            functionality.
 *
 \*-----*/

## SetupType2

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SetupType2** function displays a dialog that enables the end user to select one of the two standard setup types: Complete or Custom. These setup options are displayed with standard description text. If you want to add other setup types or change the displayed setup type names or descriptions, call SdSetupTypeEx instead.

**Caution** ▪ If an end user returns to the Setup Type dialog after using a feature dialog to select and deselect features associated with the selected setup type, those choices are lost. This occurs because the SetupType2 function automatically resets the default feature selections for the selected setup type each time it is called.

### Syntax

```
SetupType2 ( szTitle, szMsg, szReserved, nType, nReserved );
```

## Parameters

**Table 170** ▪ SetupType2 Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTitle</b>    | Specifies the title of this dialog. To display the default title Setup Type2, pass a null string ("") in this parameter.                                                                                                                                                                                         |
| <b>szMsg</b>      | Specifies the message you want to display at the top of the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                              |
| <b>szReserved</b> | Pass a null string ("") in this parameter. No other value is allowed.                                                                                                                                                                                                                                            |
| <b>nType</b>      | Specifies the default setup type when the dialog is opened. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>COMPLETE</b>—Defines the default setup type as Complete.</li> <li>● <b>CUSTOM</b>—Defines the default setup type as Custom.</li> </ul> |
| <b>nReserved</b>  | Pass zero in this parameter. No other value is allowed.                                                                                                                                                                                                                                                          |

## Return Values

**Table 171** ▪ SetupType2 Return Values

| Return Value              | Description                                                 |
|---------------------------|-------------------------------------------------------------|
| <b>COMPLETE (304)</b>     | Indicates that the Complete setup type was selected.        |
| <b>CUSTOM (303)</b>       | Indicates that the end user selected the Custom setup type. |
| <b>BACK (12)</b>          | Indicates that the end user clicked the Back button.        |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the dialog could not be displayed.           |

## Additional Information

- In an InstallScript project, if you do not display a setup type dialog, your script must do one of the following:
  - Select a setup type.
  - Call a feature selection dialog function such as SdFeatureTree.
  - Directly select features.
- To view an example of this or other dialogs for your installation, use the Dialog Sampler. In InstallShield, on the Tools menu, point to InstallScript, then click Standard Dialog Sampler or Skinned Dialog Sampler.

## SetupType2 Example

**Project** - This information applies to the following project types:

- InstallScript
- InstallScript MSI

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SetupType2 function.
 *
 * Comments:  To run this example script, create a project (or
 *             insert into a project) with several features and
 *             subfeatures with components containing files.
 *             This example includes setup of uninstallation
 *             functionality.
 *
\*-----*/

// Specify your feature name here.  These are the names you gave to
// your features in InstallShield.  A NULL ("") string
// specifies base features.

## ShowObjWizardPages

**Project** ▪ This information applies to InstallScript projects.

The **ShowObjWizardPages** function is called in a project's UI event handler to execute each included object's corresponding UI event handler. For example, calling **ShowObjWizardPages** in a project's OnFirstUIBefore event handler executes each included object's OnFirstUIBefore code.

### Syntax

```
ShowObjWizardPages ( nDirection );
```

### Parameters

**Table 172** ▪ ShowObjWizardPages Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nDirection</b> | <p>Pass one of the following predefined constants to indicate the measurement unit:</p> <ul style="list-style-type: none"> <li> <b>NEXT</b>—Specifies the following:                     <p>The first UI event handler called is that of the object listed first in the project's Components pane, then that of the object listed second, and so on.</p> <p>The <b>WizardDirection</b> function, when called in an object's UI event handler, returns the value NEXT.</p> </li> <li> <b>BACK</b>—Specifies the following:                     <p>The first UI event handler called is that of the object listed last in the project's Components pane, then that of the object listed next to last, and so on.</p> <p>The <b>WizardDirection</b> function, when called in an object's UI event handler, returns the value BACK.</p> </li> </ul> |

### Return Values

The value returned by the most recently executed object UI event handler.

## Additional Information

The objects' dialogs are displayed in one of two possible orders, depending on the value of `nDirection`. For greater control over the order in which the objects' dialogs are displayed, call the objects' `ShowxxxxxUIyyyyy` methods. For more information on object UI event handlers, see [Creating the Object's Run-Time User Interface](#).

# ShowProgramFolder

The **ShowProgramFolder** function displays a program folder.

## Syntax

```
ShowProgramFolder ( szFolder, nCommand );
```

## Parameters

**Table 173** ■ ShowProgramFolder Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFolder</b> | Specifies the name of the folder to display.                                                                                                                                                                                                                                                                                                                                 |
| <b>nCommand</b> | Specifies the state of the folder. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>SW_SHOW</b>—Show folder in normal state.</li> <li>● <b>SW_MAXIMIZE</b>—Maximize the folder.</li> <li>● <b>SW_MINIMIZE</b>—Minimize the folder.</li> <li>● <b>SW_RESTORE</b>—Restore the folder to original size.</li> </ul> |

## Return Values

This function does not return a value.

## ShowProgramFolder Example

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the ShowProgramFolder function.
*
* ShowProgramFolder displays a folder, then changes the state
* of the folder.
*
```

```

* Note: This script will not run properly if the program folder
*       "Startup" does not exist. Either create a program
*       folder called "Startup" or set the constant FOLDER so
*       that it references an existing program folder. In
*       addition, the specified folder should be closed or
*       minimized when you run this script.
*
\*-----*/

#define FOLDER "Startup"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_ShowProgramFolder(HWND);

function ExFn_ShowProgramFolder(hMSI)
begin
    // Display the specified folder.
    ShowProgramFolder (FOLDER, SW_SHOW);
    Delay (3);

    // Maximize the folder.
    ShowProgramFolder (FOLDER, SW_MAXIMIZE);
    Delay (3);

    // Restore the folder to its previous state.
    ShowProgramFolder (FOLDER, SW_RESTORE);
    Delay (3);

    // Minimize the folder.
    ShowProgramFolder (FOLDER, SW_MINIMIZE);
    Delay (3);

    // Restore the folder to its previous state.
    ShowProgramFolder (FOLDER, SW_RESTORE);
    Delay (3);

end;

```

## ShowWindow

The **ShowWindow** function sets the specified window's show state.

### Syntax

```

BOOL ShowWindow(
    HWND hWnd, // handle to window
    int nCmdShow // show state
);

```

## Parameters

**Table 174** ▪ ShowWindow Parameters

| Parameter   | Description                         |
|-------------|-------------------------------------|
| <b>hWnd</b> | Specifies the handle to the window. |

**Table 174** ▪ ShowWindow Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nCmdShow</b> | <p>Specifies the show state of the window. If the program that launched the application includes a STARTUPINFO structure, this parameter is ignored the first time the application calls ShowWindow. Otherwise, the first time ShowWindow is called, the value should be the value obtained by the WinMain function in its <i>nCmdShow</i> parameter. In subsequent calls, this parameter can be one of the following values.</p> <ul style="list-style-type: none"> <li>● <b>SW_FORCEMINIMIZE</b>—Minimizes a window, even if the thread that owns the window is not responding. This value should only be used when minimizing windows from a different thread.</li> <li>● <b>SW_HIDE</b>—Hides the window and activates another window.</li> <li>● <b>SW_MAXIMIZE</b>—Maximizes the specified window.</li> <li>● <b>SW_MINIMIZE</b>—Minimizes the specified window and activates the next top-level window in the Z order. The Z order is the position of a window in a stack of overlapping windows on the z axis, which indicates depth.</li> <li>● <b>SW_RESTORE</b>—Activates and displays the window. If the window is minimized or maximized, the system restores it to its original size and position. An application should specify this value when restoring a minimized window.</li> <li>● <b>SW_SHOW</b>—Activates the window and displays it in its current size and position.</li> <li>● <b>SW_SHOWDEFAULT</b>—Sets the show state based on the SW_ value specified in the STARTUPINFO structure passed to the CreateProcess function by the program that started the application.</li> <li>● <b>SW_SHOWMAXIMIZED</b>—Activates the window and displays it as a maximized window.</li> <li>● <b>SW_SHOWMINIMIZED</b>—Activates the window and displays it as a minimized window.</li> <li>● <b>SW_SHOWMINNOACTIVE</b>—Displays the window as a minimized window. The active window remains active.</li> <li>● <b>SW_SHOWNA</b>—Displays the window in its current size and position. The active window remains active.</li> <li>● <b>SW_SHOWNOACTIVATE</b>—Displays a window in its most recent size and position. The active window remains active.</li> <li>● <b>SW_SHOWNORMAL</b>—Activates and displays a window. If the window is minimized or maximized, it is restored to its original size and position. An application should specify this value when displaying the window for the first time.</li> </ul> |

## Return Values

**Table 175** ▪ ShowWindow Return Values

| Return Value   | Description                                            |
|----------------|--------------------------------------------------------|
| <b>Nonzero</b> | The return value is nonzero if the window was visible. |
| <b>0</b>       | The return value is 0 if the window was hidden.        |

## Additional Information

This information was adapted from the MSDN topic [ShowWindow Function](#).

# SilentReadData

The **SilentReadData** function instructs InstallShield Silent on how to read the .iss file dialog data for a custom dialog when an installation runs in silent mode (when using the `-s` switch with `Setup.exe`). Note that you can create an .iss file by calling **SilentWriteData**.

To use **SilentReadData** in your script, construct the logic so that it first checks to make sure that the installation is running in silent mode. Place the **SilentReadData** function call inside an if-else statement, based on a test of the system variable `MODE`, as shown below:

```
if (MODE=SILENTMODE) then
    // Call SilentReadData here
else
    // Make a normal, non-silent function call here
endif;
```

Custom dialogs can be resources that you call and handle in your installation script using functions like **EzDefineDialog** and **WaitOnDialog**, or they can be completely external, executed as calls to functions in DLLs. In either case, you must use **SilentReadData** to retrieve from the .iss file the dialog button's return value (Next, Back, Cancel, and so on) and any values set or returned in variables.

## Syntax

```
SilentReadData (szSection, szValName, nValType, svVal, nvVal);
```

## Parameters

**Table 176** ▪ SilentReadData Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSection</b> | Specifies the name of the dialog data section in the .iss file. Do not include the square brackets ( [ ] ). The parameter szSection takes the form <functionname>-<number>, where <functionname> is the name of the dialog function as it is used in the script, and <number> is the number of the occurrence of that dialog in the script, beginning with 0 (zero). For example, the first occurrence of the MyDialog function dialog would have a value of "MyDialog-0" in szSection, the second occurrence "MyDialog-1," the third "MyDialog-2," and so on.                                                                                                                                                                                                                                                                                                  |
| <b>szValName</b> | Specifies the value name that appears in the dialog data section of the .iss file. Every dialog has at least one value for szValName—"Result"—which identifies the value returned by the dialog button controls (BACK, NEXT, OK, or CANCEL). Other value names are used to identify values and data associated with the other dialog controls.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>nValType</b>  | Identifies the data type of the value assigned to the value name in szValName. The value itself is stored in either svVal or nvVal, depending upon the value of nValType. Pass one of the following predefined constants in this parameter: <ul style="list-style-type: none"> <li>● <b>DATA_STRING</b>—The value assigned to the value name in szValName is of type STRING. Its value will be stored in svVal.</li> <li>● <b>DATA_NUMBER</b>—The value assigned to the value name in szValName is of type NUMBER. Its value will be stored in nvVal.</li> <li>● <b>DATA_COMPONENT</b>—The value assigned to the value name in szValName is the name of a component. It will be stored in svVal.</li> <li>● <b>DATA_LIST</b>—The value assigned to the value name in szValName is the list ID for an InstallScript list. It will be stored in nvVal.</li> </ul> |
| <b>svVal</b>     | Specifies the value assigned to the value name in szValName when nValType is DATA_STRING or DATA_COMPONENT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>nvVal</b>     | Specifies the value assigned to the value name in szValName when nValType is DATA_NUMBER or DATA_LIST.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 177** ▪ SilentReadData Return Values

| Return Value | Description                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>     | <b>SilentReadData</b> successfully instructed InstallShield Silent on how to read the dialog data for the custom dialog. |

**Table 177** ▪ SilentReadData Return Values (cont.)

| Return Value | Description                                                                                                                                                                                                                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| < 0          | <p><b>SilentReadData</b> was called in an installation that is not running silently.</p>  <p><b>Note</b> ▪ If <b>SilentReadData</b> cannot read the custom dialog data in the response file, the installation is aborted.</p> |

## SilentReadData Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the functions SdMakeName, SilentReadData, and
* SilentWriteData.
*
* This example script shows how to handle a custom dialog
* in a silent installation. The resource .dll for the example
* custom dialog shown below should be stored in a compressed
* form under the Support Files/Billboards view of InstallShield.
*
* The example dialog was built from the custom dialog
* template provided with InstallShield.
*
* Dialog control IDs and other information are included in
* the RESOURCE.H file (not shown). This file, which is included
* in the first line of the example, must be inserted in the
* InstallScript view of InstallShield.
*
* The example creates a text file called Cominit.txt. If the
* installation runs in silent mode, SilentReadData is called
* and the custom dialog control selections are read from
* the .ISS file. The selections are then saved in the file
* Cominit.txt as a means of demonstrating that they were
* successfully read from the .iss file. If the installation
* runs in normal mode, the custom dialog is displayed
* and the selections are recorded in the .iss file and
* displayed in message boxes. The initial .ISS file text is
* shown after the example script.
*
\*-----*/

## SilentWriteData

The **SilentWriteData** function records selections made in custom dialogs during the installation. This selection data is written to an .iss file for use by InstallShield Silent. To write to an .iss file during an installation, run the installation using the -r switch with Setup.exe.

Custom dialogs can be resources that you call and handle in your installation script using functions like EzDefineDialog and WaitOnDialog, or they can be completely external, executed as calls to functions in DLLs. In either case, you must use SilentWriteData to record the dialog's button return value (Next, Back, Cancel, and so on) and any values set or returned in variables.

### Syntax

```
SilentWriteData ( szSection, szValName, nValType, szVal, nVal );
```

## Parameters

**Table 178** ▪ SilentWriteData Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSection</b> | Specifies the name of the dialog data section in the .iss file. Do not include the square brackets ([ ]). The parameter szSection takes the form <functionname>-<number>, where <functionname> is the name of the dialog function as it is used in the script, and <number> is the number of the occurrence of that dialog in the script, beginning with 0 (zero). For example, the first occurrence of the MyDialog function dialog would have a value of "MyDialog-0" for szSection, the second occurrence "MyDialog-1," the third "MyDialog-2," and so on.                                                                                                                                                                                                                                                                                                  |
| <b>szValName</b> | Specifies the value name that appears in the dialog data section of the .iss file. Every dialog has at least one value for szValName—"Result"—which identifies the value returned by the dialog button controls (BACK, NEXT, OK, or CANCEL). Other value names are used to identify values and data associated with the other dialog controls.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>nValType</b>  | <p>Identifies the data type of the value assigned to the value name in szValName. The value itself is stored in either szVal or nVal, depending upon the value of nValType. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>DATA_STRING</b>—The value assigned to the value name in szValName is of type STRING. Its value will be stored in szVal.</li> <li>● <b>DATA_NUMBER</b>—The value assigned to the value name in szValName is of type NUMBER. Its value will be stored in nVal.</li> <li>● <b>DATA_COMPONENT</b>—The value assigned to the value name in szValName is the name of a component. It will be stored in szVal.</li> <li>● <b>DATA_LIST</b>—The value assigned to the value name in szValName is the list ID for an InstallShield list. It is stored in nVal.</li> </ul> |
| <b>szVal</b>     | Specifies the value assigned to the value name in szValName when nValType is DATA_STRING or DATA_COMPONENT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>nVal</b>      | Specifies the value assigned to the value name in szValName when nValType is DATA_NUMBER or DATA_LIST.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Return Values

**Table 179** ▪ SilentWriteData Return Values

| Return Value | Description                                                                             |
|--------------|-----------------------------------------------------------------------------------------|
| 0            | SilentWriteData successfully wrote the dialog data for the custom dialog to Setup.iss.  |
| < 0          | SilentWriteData was unable to write the dialog data for the custom dialog to Setup.iss. |

## SilentWriteData Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the functions SdMakeName, SilentReadData, and
* SilentWriteData.
*
* This example script shows how to handle a custom dialog
* in a silent installation. The resource .dll for the example
* custom dialog shown below should be stored in a compressed
* form under the Support Files/Billboards view of InstallShield.
*
* The example dialog was built from the custom dialog
* template provided with InstallShield.
*
* Dialog control IDs and other information are included in
* the RESOURCE.H file (not shown). This file, which is included
* in the first line of the example, must be inserted in the
* InstallScript view of InstallShield.
*
* The example creates a text file called Cominit.txt. If the
* installation runs in silent mode, SilentReadData is called
* and the custom dialog control selections are read from
* the .ISS file. The selections are then saved in the file
* Cominit.txt as a means of demonstrating that they were
* successfully read from the .iss file. If the installation
* runs in normal mode, the custom dialog is displayed
* and the selections are recorded in the .iss file and
* displayed in message boxes. The initial .ISS file text is
* shown after the example script.
*
\*-----*/

## SizeOf

The **SizeOf** function retrieves the number of elements in an InstallScript array, or the size of a variable passed as an argument.

To determine the number of characters in the value of a string variable, use [StrLength](#).

### Syntax

```
SizeOf ( Item );
```

### Parameters

**Table 180** ▪ SizeOf Parameters

| Parameter | Description                         |
|-----------|-------------------------------------|
| Item      | Specifies the name of the variable. |

### Return Values

**SizeOf** returns the number of elements in an array, or the size of a variable passed as an argument.

## SizeWindow

Use the **SizeWindow** function to change the size of a specific user interface element. Specify the new size in pixels.

The installation may run under many different screen resolutions. To account for this, you need to use the **GetExtents** function to determine the overall size of the screen; then use ratios in the parameters of your **SizeWindow** function call to specify the size of your user interface object.

**Note** ▪ This function is recommended for advanced developers only.

## Syntax

SizeWindow (nObject, nDx, nDy);

## Parameters

**Table 181** ▪ SizeWindow Parameters

| Parameter      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nObject</b> | <p>Specifies the object to resize. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>BACKGROUND</b>—Indicates the main background window.</li> <li>• <b>METAFILE</b>—Indicates a billboard used during the file transfer process. <b>SizeWindow</b> does not support bitmap (.bmp) files.</li> </ul> <p></p> <p><b>Note</b> ▪ This parameter does not have any effect on metafiles that are displayed with <b>SdBitmap</b> function. <b>SdBitmap</b> automatically resizes metafiles when they are displayed.</p> <p>In addition, this parameter does not have any effect on the type of billboard that is displayed on a progress dialog when <b>Enable(BBRD)</b> is called.</p> <ul style="list-style-type: none"> <li>• <b>MMEDIA_AVI</b>—Sets the window size for next AVI file to be played. All the AVI videos are displayed with a default size. Changing the size may change the resolution and crispness of the video.</li> <li>• <b>MMEDIA_SWF</b>—Sets the window size for the Adobe Flash application file (.swf) to be played.</li> </ul> |
| <b>nDx</b>     | Specifies the horizontal size of the object in pixels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>nDy</b>     | Specifies the vertical size of the object in pixels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Return Values

**Table 182** ▪ SizeWindow Return Values

| Return Value  | Description                                               |
|---------------|-----------------------------------------------------------|
| <b>0</b>      | The function successfully changed the size of the window. |
| <b>&lt; 0</b> | The function was unable to change the size of the window. |

## Additional Information

Use the **PlayMMedia** function if you want your installation to play an Adobe Flash application file (.swf) or an AVI file.

## SizeWindow Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the SizeWindow function.
 *
 * GetExtents is called to retrieve the extents of the screen.
 * SizeWindow is then called to resize the background to half
 * the original size.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_SizeWindow(HWND);

function ExFn_SizeWindow(hMSI)
    NUMBER nDx, nDy, nObject;
begin

    // Enable the background.
    Enable (BACKGROUND);

    MessageBox ("Background at original size.", INFORMATION);

    // Get the extents of the screen.
    GetExtents (nDx, nDy);

    // Set the object to be resized.
    nObject = BACKGROUND;

    // Resize the background window to half of its original size.
    if (SizeWindow (nObject, (nDx / 2), (nDy / 2)) < 0) then
        MessageBox ("SizeWindow failed.", SEVERE);
    endif;

    MessageBox ("Background after call to SizeWindow.", INFORMATION);

end;
```

## Sprintf

The **Sprintf** function creates a string from variable data using format specifier and matching variables. Sprintf works like the Microsoft Windows API `wsprintf`.

## Syntax

```
Sprintf ( svResult, szFormat [,arg] [,...] );
```

## Parameters

**Table 183** ■ Sprintf Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svResult</b> | Returns a string created from the arguments passed in the third and subsequent parameters and formatted according the specifications in the second parameter, szFormat.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szFormat</b> | Specifies a string that can include literal text and must include one format specifier for each argument to be embedded in the string returned by svResult.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>arg</b>      | <p>You may specify up to nine arguments to be included in the message. You must have one argument for each format specifier in the message; the type of each argument must match the type of its respective format specifier.</p> <p>Sprintf generates a compiler error or fail at run time under the following conditions:</p> <ul style="list-style-type: none"> <li>• More than nine format specifiers and arguments are specified. This results in a compiler error.</li> <li>• The number of arguments does not match the number of format specifiers. When a specifier does not have a corresponding argument, the resulting string contains unpredictable characters in the specifier's position. When there are more arguments than specifiers, the excess arguments are not inserted into the resulting string.</li> <li>• A variable does not match the type of its respective format specifier. The resulting string contains unpredictable characters in the specifier's position.</li> </ul> |

## Return Values

If the Sprintf function is successful, the return value is the length—the number of characters—in the string stored in the variable svResult, not including the terminating null character.

## Sprintf Example

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the Sprintf function.
 *
 * This script gets the capacity of drive C: and then calls
 * Sprintf to create a formatted message. That message
 * includes the drive letter and disk size, which are stored
 * in variables. The message is then displayed.
 *
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_Sprintf(HWND);

function ExFn_Sprintf(hMSI)
    STRING  svResult, svMssg;
    NUMBER  nvResult;
begin

    // Set up the string parameter for the call to GetSystemInfo.
    svResult = "C:";

    // Get the capacity of drive C.
    GetSystemInfo (DISK_TOTALSPACE, nvResult, svResult);

    // Build a message that incorporates the values
    // returned by GetSystemInfo.
    Sprintf (svMssg, "Total disk space on drive %s is %ld bytes.",
            svResult, nvResult);

    // Display the message.
    MessageBox (svMssg, INFORMATION);

end;

```

## SprintfBox

**Project** • This information applies to the following project types:

- Basic MSI
- InstallScript
- InstallScript MSI

The **SprintfBox** function presents a message box containing one of three icons, a title, and a formatted message. The message can contain variables that are formatted according to commands that you enter.

**SprintfBox** is similar to **MessageBox**, but **SprintfBox** permits much more flexible control over displayed items.

**Caution** - Multiple null-delimited strings should not be used, except for passing to external functionality.

The **SprintfBox** function uses the Microsoft Windows API **MessageBox** to create the message box. The operating environment, not InstallShield, determines the size and location of the message box. The operating environment also generates the text for the OK button in the local language (the language that the operating system is running under). You cannot change the text in this button. For more information regarding the use of Windows **MessageBox** types, consult the description of the **MessageBox** Windows API function in the appropriate Windows SDK.

Note the following when using Windows message box constants:

- Some Windows **MessageBox** type constants are predefined in the `ISRTWindows.h` file that is provided in the *InstallShield Program Files Folder\Script\Isrt\Include* folder. This file is automatically included in your installation when you include `Ifx.h` in your script. You do not need to redefine any constants that are defined in `ISRTWindows.h`; doing so will result in a compiler warning. To determine which constants are predefined, refer to the `ISRTWindows.h` file.
- To use constants that are not defined in `ISRTWindows.h`, you must define them (using `#define`) in the declaration block of your installation script. You cannot simply include the `Windows.h` file that is usually part of a C++ program. The values that you need to assign to the undefined constants can generally be found in an include file that is provided with the appropriate Windows SDK or development tool. (For Microsoft Visual C++, most constants can be found in the `Winuser.h` file, which is located in the *InstallShield Program Files Folder\Script\Resource* folder.)
- Windows and InstallShield message box constants cannot be used together in an installation. If an InstallShield message box constant is combined with a Windows message box constant using the OR operator (`|`), the Windows message box constant is ignored.
- Some Windows message box styles are not supported on some Windows platforms. To determine whether a particular style is supported on the operating systems targeted by the installation, consult the appropriate Windows SDK.

## Syntax

```
SprintfBox ( nType, szTitle, szFormat [,arg] [,...] );
```

## Parameters

**Table 184** • SprintfBox Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nType</b>    | <p>Specifies the type of icon to display in the message box. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● INFORMATION</li> <li>● WARNING</li> <li>● SEVERE</li> </ul> <p>Advanced developers familiar with the Windows APIs can specify any style of message box by using the message box style constants in the parameter nType. See the description for the MessageBox or WinMessageBox API in the programming manual for your operating environment. If you are using any of the message box styles, the InstallShield SprintfBox function returns the return value from the Windows API. Therefore, you must use the Windows API return values in your script.</p> <p>For example, if you pass YES NO CANCEL as the first parameter, the SprintfBox message box has Yes, No, and Cancel buttons. The respective button return values, as defined by the Windows API MessageBox, are 6 (IDYES), 7 (IDNO), and 2 (IDCANCEL). You must use the appropriate constant values in your script, either as number literals, or as constants defined as the number literals in the declare block of your script.</p> <div>  <p><b>Tip</b> • Advanced developers can use MB_STYLE directly as the first parameter of the SprintfBox function to replace the constants SEVERE, WARNING, or INFORMATION. The value of MB_STYLE is listed in the Windows.h file. You can either enter the value directly in the parameter nType, or you can use the #define preprocessor directive to define the constants associated with the value.</p> </div> |
| <b>szTitle</b>  | Specifies the title of the message box. To display the default title Error, pass a null string ("") in this parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>szFormat</b> | Specifies a string that includes a format specifier for each argument to be included in the message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 184** ■ sprintfBox Parameters (cont.)

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>arg</b> | <p>Specifies up to 10 arguments to be included in the message. There must be one argument for each format specifier in the message; the type of each argument must match the type of its respective format specifier. sprintfBox generates a compiler error or fails at run time under the following conditions:</p> <ul style="list-style-type: none"> <li>• More than 10 format specifiers and arguments are specified: compiler error.</li> <li>• The number of arguments does not match the number of format specifiers. When a specifier does not have a corresponding argument, the resulting string contains unpredictable characters in the specifier's position. When there are more arguments than specifiers, the excess arguments are not inserted into the resulting string.</li> <li>• A variable does not match the type of its respective format specifier.</li> <li>• A character itself is passed, rather than its numeric ASCII value or the return from the <b>STRTOCHAR</b> function, with the format specifier %c.</li> </ul> |

## Return Values

The return value is not significant unless you are using standard Microsoft Windows message box styles. If you are using these styles, the return value is the same as the return value from the MessageBox API functions.

## Additional Information

The dialog that is displayed by the sprintfBox function cannot be displayed with a skin; it appears the same regardless of whether you have specified a skin.

## SprintfBox Example

**Project** ■ This information applies to the following project types:

- Basic MSI
- InstallScript
- InstallScript MSI

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the sprintfBox function.
*
```

```

* This script gets the capacity of drive C: and then calls
* SprintfBox to create and display a formatted message. That
* message includes the drive letter and disk size, which are
* stored in variables.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_SprintfBox(HWND);

function ExFn_SprintfBox(hMSI)
    STRING  svResult;
    NUMBER  nvResult;
begin

    // Set up the string parameter for the call to GetSystemInfo.
    svResult = "C:.";

    // Get the capacity of drive C.
    GetSystemInfo (DISK_TOTALSPACE, nvResult, svResult);

    // Build and display a message that incorporates
    // the values returned by GetSystemInfo.
    SprintfBox (INFORMATION, "System Information",
                "Total disk space on drive %s is %ld bytes.",
                svResult, nvResult);

end;

```

## SprintfMsiLog

**Project** • This information applies to the following project types:

- Basic MSI
- InstallScript MSI

The **SprintfMsiLog** function writes a message directly to the Windows Installer log file.

### Syntax

```
SprintfMsiLog ( szFormat [,arg] [... ] );
```

## Parameters

**Table 185** • SprintfMsiLog Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFormat</b> | Specifies a string that can include literal text and must include one format specifier for each argument to be embedded in the string returned by <code>svResult</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>arg</b>      | <p>You can specify up to nine arguments to be included in the message. You must have one argument for each format specifier in the message. The type of each argument must match the type of its respective format specifier.</p> <p>SprintfMsiLog generates a compiler error or fail at run time under the following conditions:</p> <ul style="list-style-type: none"> <li>• More than nine format specifiers and arguments are specified. This results in a compiler error.</li> <li>• The number of arguments does not match the number of format specifiers. When a specifier does not have a corresponding argument, the resulting string contains unpredictable characters in the specifier's position. When there are more arguments than specifiers, the excess arguments are not inserted into the resulting string.</li> <li>• A variable does not match the type of its respective format specifier. The resulting string contains unpredictable characters in the specifier's position.</li> </ul> |

## Return Values

There are no return values for this function. If the function is successful, the values are written to the Windows Installer log file. If the function fails, the values are not written to the Windows Installer log file.

# SQLBrowse

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLBrowse2** function supersedes the **SQLBrowse** function.

The **SQLBrowse** function creates a dialog that lets an end user display a list of all SQL Servers that are available on the network.

This function is in the `SQLRT.obl` file for InstallScript projects, and in the `SQLCONV.obl` file for InstallScript MSI projects. If you are using the SQL Scripts view in InstallShield, the appropriate file is automatically added to your linker settings. However, if you are not using this view, add the appropriate file to your linker settings: On the Build menu, click Settings, and then add it to the Libraries (.obl) box.

## Syntax

```
SQLBrowse( svServer );
```

## Parameters

**Table 186** ▪ SQLBrowse Parameters

| Parameter       | Description                                                                                                                                                                                                                  |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svServer</b> | When the function returns, this parameter contains the string with the server name that the end user selected.<br><br>If an alias name was used to connect to a SQL Server database, this parameter contains the alias name. |

## Return Values

**Table 187** ▪ SQLBrowse Return Values

| Return Value              | Description                             |
|---------------------------|-----------------------------------------|
| <b>NEXT</b>               | The end user clicked the OK button.     |
| <b>CANCEL</b>             | The end user clicked the Cancel button. |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.      |

# SQLBrowse2

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLBrowse2** function creates a dialog that lets an end user display a list of all database servers that are available on the network for the database technologies specified for a connection.

## Syntax

```
SQLBrowse2( szConnection, svServer );
```

## Parameters

**Table 188** ▪ SQLBrowse2 Parameters

| Parameter           | Description                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b> | Specifies the name of the connection that you created in the SQL Scripts view.                                                                                                                                               |
| <b>svServer</b>     | When the function returns, this parameter contains the string with the server name that the end user selected.<br><br>If an alias name was used to connect to a SQL Server database, this parameter contains the alias name. |

## Return Values

**Table 189** ▪ SQLBrowse2 Return Values

| Return Value              | Description                             |
|---------------------------|-----------------------------------------|
| <b>NEXT</b>               | The end user clicked the OK button.     |
| <b>CANCEL</b>             | The end user clicked the Cancel button. |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.      |

# SQLDatabaseBrowse

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLDatabaseBrowse** function creates a dialog that lets the end user display a list of all database catalogs that are available on the specified database server. This function calls **SQLRTGetDatabases**, which uses SQLRT.d11 for InstallScript projects and ISSQLSRV.d11 for InstallScript MSI projects.

**Note** ▪ The **SQLDatabaseBrowse** function uses settings from the SQL settings file; therefore, it can be called only after **SQLRTInitialize2** has already been called.

## Syntax

```
SQLDatabaseBrowse( szConnection, szServer, bvWindowsLogin, szUser, szPassword, svDBCatalog );
```

## Parameters

**Table 190** ▪ SQLDatabaseBrowse Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b>   | Specifies the name of the connection that you created in the SQL Scripts view.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>svServer</b>       | When the function returns, this parameter contains the string with the server name the end user selected.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>bvWindowsLogin</b> | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |
| <b>szUser</b>         | Specifies the default string to display in the Login ID edit box. Once the dialog function returns, this parameter contains the Login ID that the end user entered in the edit field. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.                                                                                                                                                                                                                            |
| <b>szPassword</b>     | Specifies the default string to display in the Password edit field. Once the dialog function returns, this parameter contains the password that the end user entered in the edit field. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.                                                                                                                                                                                                                          |
| <b>svDBCatalog</b>    | Specifies the name of the SQL database catalog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Return Values

**Table 191** ▪ SQLDatabaseBrowse Return Values

| Return Value              | Description                             |
|---------------------------|-----------------------------------------|
| <b>NEXT</b>               | The end user clicked the OK button.     |
| <b>CANCEL</b>             | The end user clicked the Cancel button. |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.      |

# SQLRTComponentInstall

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTComponentInstall** function executes the SQL script that is associated with the specified component if the script is scheduled to run during installation.

**Note** ▪ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an InstallScript project or the *OnSQLLogin* event handler is called in an InstallScript MSI project, call the [SQLRTInitialize2](#) function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTComponentInstall( szComponent );
```

## Parameters

**Table 192** ▪ SQLRTComponentInstall Parameters

| Parameter          | Description                                                       |
|--------------------|-------------------------------------------------------------------|
| <b>szComponent</b> | Specifies the name of the component that contains the SQL script. |

## Return Values

**Table 193** ▪ SQLRTComponentInstall Return Values

| Return Value                           | Description                                       |
|----------------------------------------|---------------------------------------------------|
| <b>&gt;=ISERR_SUCCESS</b>              | This function was able to execute the SQL script. |
| <b>&lt;ISERR_SUCCESS</b>               | This function failed to execute the SQL script.   |
| <b>SQL_ERROR_NOT_INITIALIZED (-10)</b> | SQLRT.dll is not loaded.                          |

# SQLRTComponentUninstall

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTComponentUninstall** function executes the SQL script that is associated with the specified component if the script is scheduled to run during uninstallation.

**Note** ▪ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an *InstallScript* project or the *OnSQLLogin* event handler is called in an *InstallScript MSI* project, call the [SQLRTInitialize2](#) function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTComponentUninstall( szComponent );
```

## Parameters

**Table 194** ▪ SQLRTComponentUninstall Parameters

| Parameter          | Description                                                       |
|--------------------|-------------------------------------------------------------------|
| <b>szComponent</b> | Specifies the name of the component that contains the SQL script. |

## Return Values

**Table 195** ▪ SQLRTComponentUninstall Return Values

| Return Value                           | Description                                       |
|----------------------------------------|---------------------------------------------------|
| <b>&gt;=ISERR_SUCCESS</b>              | This function was able to execute the SQL script. |
| <b>&lt;ISERR_SUCCESS</b>               | This function failed to execute the SQL script.   |
| <b>SQL_ERROR_NOT_INITIALIZED (-10)</b> | SQLRT.dll is not loaded.                          |

# SQLRTConnect

**Project** ▪ This information applies to *InstallScript* projects.

The [SQLRTConnect2](#) function supersedes the **SQLRTConnect** function.

The **SQLRTConnect** function establishes a connection using the specified credential.

**Note** ▪ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an *InstallScript* project or the *OnSQLLogin* event handler is called in an *InstallScript MSI* project, call the [SQLRTInitialize2](#) function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTConnect( szConnection, szServer, bTrust, szUserName, szPassword );
```

## Parameters

**Table 196** ▪ SQLRTConnect Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b> | Specifies the name of the connection that you created in the SQL Scripts view.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>szServer</b>     | Specifies the SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>bTrust</b>       | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |
| <b>szUserName</b>   | Specifies the SQL Server login information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szPassword</b>   | Specifies the password associated with a user account.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Return Values

**Table 197** ▪ SQLRTConnect Return Values

| Return Value                           | Description                                       |
|----------------------------------------|---------------------------------------------------|
| <b>&gt;=ISERR_SUCCESS</b>              | This function was able to establish a connection. |
| <b>&lt;ISERR_SUCCESS</b>               | This function failed to establish a connection.   |
| <b>SQL_ERROR_NOT_INITIALIZED (-10)</b> | SQLRT.dll is not loaded.                          |

# SQLRTConnect2

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTConnect2** function establishes a connection. This function must be called before file transfer if the connection is to be used to run scripts during installation. **SQLRTConnect2** returns the database server name when it fails to establish the connection.

---

**Note** ▪ The **SQLRTConnect2** function uses SQLRT.dll; therefore, it can be called only after **SQLRTInitialize2** has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTConnect2( szConnection, szServer, bWinLogin, szUser, szPassword, szDatabaseServer );
```

## Parameters

**Table 198** ▪ SQLRTConnect2 Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b>     | Specifies the name of the connection that you created in the SQL Scripts view.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>szServer</b>         | Specifies the SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>bWinLogin</b>        | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |
| <b>szUser</b>           | Specifies the SQL Server login information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szPassword</b>       | Specifies the password associated with a user account.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szDatabaseServer</b> | Specifies the database server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Return Values

**Table 199** ▪ SQLRTConnect2 Return Values

| Return Value                           | Description                                       |
|----------------------------------------|---------------------------------------------------|
| <b>&gt;=ISERR_SUCCESS</b>              | This function was able to establish a connection. |
| <b>&lt;ISERR_SUCCESS</b>               | This function failed to establish a connection.   |
| <b>SQL_ERROR_NOT_INITIALIZED (-10)</b> | SQLRT.dll is not loaded.                          |

## Additional Information

If you want to be able to specify which catalog to connect to, replace the **SQLRTConnect2** function call in the OnSQLServerInitialize event with the **SQLRTConnectDB** function call. For more information, see [SQLRTConnectDB](#).

# SQLRTConnectDB

**Project** ▪ This information applies to InstallScript projects.

To establish a connection to a specific catalog, replace the **SQLRTConnect2** function call in the OnSQLServerInitialize event with the **SQLRTConnectDB** function call. Pass the catalog name as the szDB parameter for **SQLRTConnectDB**.

If you want end users to be able to specify the catalog at run time, pass an end user-defined variable as szDB.

---

**Note** ▪ The **SQLRTConnectDB** function uses SQLRT.dll; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTConnectDB( szConnection, szDB, szServer, bWinLogin, szUser, szPassword );
```

## Parameters

**Table 200** ▪ SQLRTConnectDB Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b> | Specifies the SQL Server connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>szDB</b>         | <p>Specifies the catalog that you want to connect to.</p> <p>To specify multiple catalogs, separate each with a semicolon (;).</p> <p>If you want end users to be able to specify the catalog at run time, pass an end user-defined variable as szDB.</p>                                                                                                                                                                                                                                                                     |
| <b>szServer</b>     | Specifies the SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>bWinLogin</b>    | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |
| <b>szUser</b>       | Specifies the SQL Server login information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szPassword</b>   | Specifies the password associated with a user account.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Return Values

**Table 201** ▪ SQLRTConnectDB Return Values

| Return Value                           | Description                                       |
|----------------------------------------|---------------------------------------------------|
| <b>&gt;=ISERR_SUCCESS</b>              | This function was able to establish a connection. |
| <b>&lt;ISERR_SUCCESS</b>               | This function failed to establish a connection.   |
| <b>SQL_ERROR_NOT_INITIALIZED (-10)</b> | SQLRT.dll is not loaded.                          |

# SQLRTDoRollbackAll

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTDoRollbackAll** function executes all of SQL scripts scheduled to run during rollback.

**Note** ▪ The **SQLRTDoRollbackAll** function uses `SQLRT.dll`; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTDoRollbackAll();
```

## Parameters

**SQLRTDoRollbackAll** takes no parameters.

## Return Values

**Table 202** ▪ SQLRTDoRollbackAll Return Values

| Return Value                                 | Description                                 |
|----------------------------------------------|---------------------------------------------|
| <code>&gt;=ISERR_SUCCESS</code>              | This function was able to execute a script. |
| <code>&lt;ISERR_SUCCESS</code>               | This function failed to execute a script.   |
| <code>SQL_ERROR_NOT_INITIALIZED (-10)</code> | <code>SQLRT.dll</code> is not loaded.       |

# SQLRTGetBatchList

**Project** ▪ This information applies to *InstallScript* projects.

The **SQLRTGetBatchList** function returns the list of components that are associated with SQL scripts that need to be run when batch mode is enabled.

**Note** ▪ The **SQLRTGetBatchList** function uses `SQLRT.dll`; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetBatchList( nOperation );
```

## Parameters

**Table 203** ▪ SQLRTGetBatchList Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOperation</b> | <p>Pass either of the following constants through this parameter:</p> <ul style="list-style-type: none"> <li>• <b>SQL_BATCH_INSTALL</b>—Obtains the list of SQL scripts scheduled to be run during installation.</li> <li>• <b>SQL_BATCH_UNINSTALL</b>—Obtains the list of SQL scripts scheduled to be run during uninstallation.</li> </ul> |

## Return Values

**Table 204** ▪ SQLRTGetBatchList Return Values

| Return Value           | Description                        |
|------------------------|------------------------------------|
| <b>listConnections</b> | Returns a list of component names. |

## Additional Information

For details about batch mode, see [Specifying the Order for Running Multiple SQL Scripts That Are Associated with a Connection](#).

# SQLRTGetBatchMode

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTGetBatchMode** function returns whether the batch mode is enabled or disabled.

**Note** ▪ The **SQLRTGetBatchMode** function uses `SQLRT.dll`; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see [Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects](#).

## Syntax

```
SQLRTGetBatchMode();
```

## Parameters

**SQLRTGetBatchMode** takes no parameters.

## Return Values

**Table 205** ▪ SQLRTGetBatchMode Return Values

| Return Value | Description             |
|--------------|-------------------------|
| TRUE         | Batch mode is enabled.  |
| FALSE        | Batch mode is disabled. |

## Additional Information

For details about batch mode, see [Specifying the Order for Running Multiple SQL Scripts That Are Associated with a Connection](#).

# SQLRTGetBrowseOption

**Project** ▪ This information applies to *InstallScript* projects.

The **SQLRTGetBrowseOption** function returns the current value of the browse option for the SQL Server browse combo box and list box controls, which can display local servers, remote servers, server aliases, or a combination of these types.

**Note** ▪ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an *InstallScript* project or the *OnSQLLogin* event handler is called in an *InstallScript MSI* project, call the [SQLRTInitialize2](#) function first. To learn more, see [Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects](#).

## Syntax

```
SQLRTGetBrowseOption( );
```

## Parameters

**SQLRTGetBrowseOption** takes no parameters.

## Return Values

**Table 206** ▪ SQLRTGetBrowseOption Return Values

| Return Value | Description                                                                                                                                                                                                                                                                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>     | <p>The SQL Server browse combo box and list box controls show all available SQL Servers (local servers, remote servers , and server aliases).</p> <p>This is the return value if <b>SQL_BROWSE_ALL</b> or zero (0) is passed for the nBrowseOption parameter of <b>SQLRTSetBrowseOption</b>, or if the <b>SQLRTSetBrowseOption</b> function is not called.</p> |
| <b>1</b>     | <p>The SQL Server browse combo box and list box controls show all available local SQL Servers.</p> <p>This is the return value if <b>SQL_BROWSE_LOCAL</b> or 1 is passed for the nBrowseOption parameter of <b>SQLRTSetBrowseOption</b>.</p>                                                                                                                   |
| <b>2</b>     | <p>The SQL Server browse combo box and list box controls show all available remote SQL Servers.</p> <p>This is the return value if <b>SQL_BROWSE_REMOTE</b> or 2 is passed for the nBrowseOption parameter of <b>SQLRTSetBrowseOption</b>.</p>                                                                                                                 |
| <b>3</b>     | <p>The SQL Server browse combo box and list box controls show all available local SQL Servers and remove SQL Servers.</p> <p>This is the return value if <b>SQL_BROWSE_LOCAL   SQL_BROWSE_REMOTE</b> or 3 is passed for the nBrowseOption parameter of <b>SQLRTSetBrowseOption</b>.</p>                                                                        |
| <b>4</b>     | <p>The SQL Server browse combo box and list box controls show all available SQL Server aliases.</p> <p>This is the return value if <b>SQL_BROWSE_ALIAS</b> or 4 is passed for the nBrowseOption parameter of <b>SQLRTSetBrowseOption</b>.</p>                                                                                                                  |
| <b>5</b>     | <p>The SQL Server browse combo box and list box controls show all available local SQL Servers and SQL Server aliases.</p> <p>This is the return value if <b>SQL_BROWSE_LOCAL   SQL_BROWSE_ALIAS</b> or 5 is passed for the nBrowseOption parameter of <b>SQLRTSetBrowseOption</b>.</p>                                                                         |
| <b>6</b>     | <p>The SQL Server browse combo box and list box controls show all available remote SQL Servers and SQL Server aliases.</p> <p>This is the return value if <b>SQL_BROWSE_REMOTE   SQL_BROWSE_ALIAS</b> or 6 is passed for the nBrowseOption parameter of <b>SQLRTSetBrowseOption</b>.</p>                                                                       |

**Table 206** ▪ SQLRTGetBrowseOption Return Values (cont.)

| Return Value | Description                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7            | <p>The SQL Server browse combo box and list box controls show all available SQL Servers (local servers, remote servers , and server aliases).</p> <p>This is the return value if <code>SQL_BROWSE_LOCAL</code>   <code>SQL_BROWSE_REMOTE</code>   <code>SQL_BROWSE_ALIAS</code> or 7 is passed for the <code>nBrowseOption</code> parameter of <b>SQLRTSetBrowseOption</b>.</p> |

## SQLRTGetComponentScriptError

**Project** ▪ This information applies to InstallScript projects.

The [SQLRTGetComponentScriptError2](#) function supersedes the **SQLRTGetComponentScriptError** function.

The **SQLRTGetComponentScriptError** function retrieves the last error while executing a SQL script that is associated with the component.

**Note** ▪ The **SQLRTGetComponentScriptError** function uses `SQLRT.dll`; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

### Syntax

```
SQLRTGetComponentScriptError( szComponent, szMessage, nvErrorType, nvErrorLine );
```

## Parameters

**Table 207** ▪ SQLRTGetComponentScriptError Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szComponent</b> | Specifies the name of the component that is associated with the script.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>szMessage</b>   | Specifies the error message that the database server returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>nvErrorType</b> | Specifies the type of error. Valid types are: <ul style="list-style-type: none"> <li>• <b>SQL_ERROR_SCRIPT_UNABLE_OPEN_FILE</b>—Failed to open the script file.</li> <li>• <b>SQL_ERROR_SCRIPT_CONNECTION_NOT_OPEN</b>—The specified connection is not opened.</li> <li>• <b>SQL_ERROR_GET_SCHEMA_VERSION</b>—Error while attempting to get the schema version from the target database.</li> <li>• <b>SQL_ERROR_SET_SCHEMA_VERSION</b>—Error while attempting to set the schema version to the target database.</li> <li>• <b>SQL_ERROR_SCRIPT_COMMAND_ERROR</b>—Failed to execute a SQL batch.</li> </ul> |
| <b>nvErrorLine</b> | Specifies the line number of the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Return Values

**Table 208** ▪ SQLRTGetComponentScriptError Return Values

| Return Value | Description                  |
|--------------|------------------------------|
| <b>TRUE</b>  | One or more errors occurred. |
| <b>FALSE</b> | No errors occurred.          |

# SQLRTGetComponentScriptError2

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTGetComponentScriptError2** function retrieves the last error while executing a SQL script that is associated with the component. This function takes several parameters (szScriptName, szTechnology, szServer, and szDB) that the **SQLRTGetComponentScriptError** function does not.

**Note** ▪ The **SQLRTGetComponentScriptError** function uses `SQLRT.dll`; therefore, it can be called only after **SQLRTInitialize2** has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetComponentScriptError2( szComponent, szMessage, nvErrorType, nvErrorLine, szScriptName,  
                             szTechnology, szServer, szDB );
```

## Parameters

**Table 209** ▪ SQLRTGetComponentScriptError2 Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szComponent</b>  | Specifies the name of the component that is associated with the script.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>szMessage</b>    | Specifies the error message that the database server returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>nvErrorType</b>  | Specifies the type of error. Valid types are: <ul style="list-style-type: none"> <li>● <b>SQL_ERROR_SCRIPT_UNABLE_OPEN_FILE</b>—Failed to open the script file.</li> <li>● <b>SQL_ERROR_SCRIPT_CONNECTION_NOT_OPEN</b>—The specified connection is not opened.</li> <li>● <b>SQL_ERROR_GET_SCHEMA_VERSION</b>—Error while attempting to get the schema version from the target database.</li> <li>● <b>SQL_ERROR_SET_SCHEMA_VERSION</b>—Error while attempting to set the schema version to the target database.</li> <li>● <b>SQL_ERROR_SCRIPT_COMMAND_ERROR</b>—Failed to execute a SQL batch.</li> </ul> |
| <b>nvErrorLine</b>  | Specifies the line number of the error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>szScriptName</b> | Specifies the name of the script.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szTechnology</b> | Specifies the name of the database server product: Microsoft SQL Server, Oracle, or MySQL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>szServer</b>     | Specifies the name of the target database server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>szDB</b>         | Specifies the name of the target database catalog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Return Values

**Table 210** ▪ SQLRTGetComponentScriptError Return Values

| Return Value | Description                  |
|--------------|------------------------------|
| <b>TRUE</b>  | One or more errors occurred. |
| <b>FALSE</b> | No errors occurred.          |

# SQLRTGetConnectionAuthentication

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLRTGetConnectionAuthentication** function gets the default SQL Server connection authentication type.

**Note** ▪ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an *InstallScript* project or the *OnSQLLogin* event handler is called in an *InstallScript MSI* project, call the [SQLRTInitialize2](#) function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetConnectionAuthentication( szConnection );
```

## Parameters

**Table 211** ▪ SQLRTGetConnectionAuthentication Parameters

| Parameter           | Description                          |
|---------------------|--------------------------------------|
| <b>szConnection</b> | Specifies the SQL Server connection. |

## Return Values

**Table 212** ▪ SQLRTGetConnectionAuthentication Return Values

| Return Value | Description                     |
|--------------|---------------------------------|
| <b>TRUE</b>  | Perform Windows authentication. |
| <b>FALSE</b> | Perform SQL authentication.     |

# SQLRTGetConnectionInfo

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLRTGetConnectionInfo** function retrieves strings containing the connection information (the default server, database, default user name, and default password).

**Note** ▪ The **SQLRTGetConnectionInfo** function uses **SQLRT.dll** in *InstallScript* projects and **ISSQLSRV.dll** in *InstallScript MSI* projects; therefore, it can be called only after **SQLRTInitialize2** has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetConnectionInfo( szConnection, szServer, szDB, szUser, szPassword );
```

## Parameters

**Table 213** ▪ SQLRTGetConnectionInfo Parameters

| Parameter           | Description                                            |
|---------------------|--------------------------------------------------------|
| <b>szConnection</b> | Specifies the SQL Server connection                    |
| <b>szServer</b>     | Specifies the SQL Server.                              |
| <b>szDB</b>         | Specifies the SQL Server database.                     |
| <b>szUser</b>       | Specifies the SQL Server login information.            |
| <b>szPassword</b>   | Specifies the password associated with a user account. |

## Return Values

**Table 214** ▪ SQLRTGetConnectionInfo Return Values

| Return Value                           | Description                                       |
|----------------------------------------|---------------------------------------------------|
| <b>&gt;=ISERR_SUCCESS</b>              | This function was able to establish a connection. |
| <b>&lt;ISERR_SUCCESS</b>               | This function failed to establish a connection.   |
| <b>SQL_ERROR_NOT_INITIALIZED (-10)</b> | SQLRT.dll is not loaded.                          |

# SQLRTGetConnections

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLRTGetConnections** function retrieves a string list of connections that are present in the settings file.

**Note** ▪ The **SQLRTGetConnections** function uses `SQLRT.dll` in *InstallScript* projects and `ISSQLSRV.dll` in *InstallScript MSI* projects; therefore, it can be called only after **SQLRTInitialize2** has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetConnections( );
```

## Parameters

**SQLRTGetConnections** takes no parameters.

## Return Values

**Table 215** ▪ SQLRTGetConnections Return Values

| Return Value            | Description                         |
|-------------------------|-------------------------------------|
| <b>listConnections;</b> | Returns a list of connection names. |

# SQLRTGetDatabases

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLRTGetDatabases** function returns a list of database catalogs that are available on the specified database server.

**Note** ▪ If you want to call any built-in SQL-related function before the `OnSQLServerInitialize` event handler is called in an *InstallScript* project or the `OnSQLLogin` event handler is called in an *InstallScript MSI* project, call the **SQLRTInitialize2** function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetDatabases( szConnection, szServer, bTrust, szUserName, szPassword );
```

## Parameters

**Table 216** ▪ SQLRTGetDatabases Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b> | Specifies the name of the connection that you created in the SQL Scripts view.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>szServer</b>     | Specifies the SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>bTrust</b>       | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |
| <b>szUserName</b>   | Specifies the SQL Server login information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szPassword</b>   | Specifies the password associated with a user account.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Return Values

Returns a list of the database catalogs that are available on the target database server.

# SQLRTGetErrorMessage

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTGetErrorMessage** function returns the descriptive message of the last error encountered by the SQL run time when a connection is being opened.

**Note** ▪ **SQLRTGetErrorMessage** calls [SQLRTGetLastError2](#), which uses SQLRT.dll and settings from the SQL settings file; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see [Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects](#).

## Syntax

```
SQLRTGetErrorMessage( svMessage );
```

## Parameters

**Table 217** ▪ SQLRTGetErrorMessage Parameters

| Parameter        | Description                      |
|------------------|----------------------------------|
| <b>svMessage</b> | Specifies the SQL error message. |

## Return Values

**Table 218** ▪ SQLRTGetErrorMessage Return Values

| Return Value                     | Description                             |
|----------------------------------|-----------------------------------------|
| <b>ISERR_SUCCESS</b>             | The function was successfully executed. |
| <b>SQL_ERROR_NOT_INITIALIZED</b> | SQLRT.dll is not loaded.                |

# SQLRTGetLastError

**Project** ▪ This information applies to InstallScript projects.

The [SQLRTGetLastError2](#) function supersedes the **SQLRTGetLastError** function.

The **SQLRTGetLastError** function returns the text of the last error encountered by the SQL run time. **SQLRTGetLastError** also loads the proper SQL error message.

**Note** ▪ The **SQLRTGetLastError** function uses SQLRT.dll and settings from the SQL settings file; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetLastError( szError );
```

## Parameters

**Table 219** ▪ SQLRTGetLastError Parameters

| Parameter      | Description              |
|----------------|--------------------------|
| <b>szError</b> | Specifies the SQL error. |

## Return Values

None

# SQLRTGetLastError2

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTGetLastError2** function returns detailed information about the last error encountered by the SQL run time. **SQLRTGetLastError2** also loads the proper SQL error message.

**Note** ▪ The **SQLRTGetLastError2** function uses `SQLRT.dll` and settings from the SQL settings file; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see [Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects](#).

## Syntax

```
SQLRTGetLastError2( nvErrorCode, svMessage, svTechnology, svConnection, svServer, svDBCatalog );
```

## Parameters

**Table 220** ▪ SQLRTGetLastError2 Parameters

| Parameter           | Description                                                                          |
|---------------------|--------------------------------------------------------------------------------------|
| <b>nvErrorCode</b>  | Specifies the SQL error code.                                                        |
| <b>svMessage</b>    | Specifies the SQL error message.                                                     |
| <b>svTechnology</b> | Specifies the type of server (such as Microsoft SQL Server or Oracle) that was used. |
| <b>svConnection</b> | Specifies the SQL error code.                                                        |
| <b>svServer</b>     | Specifies the name of the SQL database server.                                       |
| <b>svDBCatalog</b>  | Specifies the name of the SQL database catalog.                                      |

## Return Values

None

# SQLRTGetScriptErrorMessage

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTGetScriptErrorMessage** function returns the descriptive message of the last error encountered by the SQL run time when a SQL script is executing.

**Note** ▪ **SQLRTGetScriptErrorMessage** calls **SQLRTGetComponentScriptError2**, which uses **SQLRT.dll** and settings from the SQL settings file; therefore, it can be called only after **SQLRTInitialize2** has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetScriptErrorMessage( svMessage );
```

## Parameters

**Table 221** ▪ SQLRTGetScriptErrorMessage Parameters

| Parameter        | Description                      |
|------------------|----------------------------------|
| <b>svMessage</b> | Specifies the SQL error message. |

## Return Values

**Table 222** ▪ SQLRTGetScriptErrorMessage Return Values

| Return Value                     | Description                             |
|----------------------------------|-----------------------------------------|
| <b>ISERR_SUCCESS</b>             | The function was successfully executed. |
| <b>SQL_ERROR_NOT_INITIALIZED</b> | SQLRT.dll is not loaded.                |

# SQLRTGetServers

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLRTGetServers** function returns a list of database servers on the network for all database technologies included in the installation. When **bFilter** is **TRUE**, it returns only local database servers.

**Note** ▪ If you want to call any built-in SQL-related function before the **OnSQLServerInitialize** event handler is called in an *InstallScript* project or the **OnSQLLogin** event handler is called in an *InstallScript MSI* project, call the **SQLRTInitialize2** function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetServers( bFilter );
```

## Parameters

**Table 223** ■ SQLRTGetServers Parameters

| Parameter      | Description                                                                                                                                                                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bFilter</b> | <p>Specifies whether the list of database servers that is returned includes only local database servers:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Return only local database servers.</li> <li>● <b>FALSE</b>—Return all database servers.</li> </ul> |

## Return Values

Returns a list of the database servers available on the network for all database technologies included in the installation.

# SQLRTGetServers2

**Project** ■ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLRTGetServers2** function returns a list of database servers for the database technologies that are specified for a connection. When *szConnection* is empty, this function behaves as [SQLRTGetServers](#).

**Note** ■ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an *InstallScript* project or the *OnSQLLogin* event handler is called in an *InstallScript MSI* project, call the [SQLRTInitialize2](#) function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTGetServers2( szConnection, bFilter );
```

## Parameters

**Table 224** ▪ SQLRTGetServers2 Parameters

| Parameter           | Description                                                                                                                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b> | Specifies a connection. If this parameter is empty, the function returns a list of database servers on the network for all database technologies included in the installation.                                                                                 |
| <b>bFilter</b>      | Specifies whether the list of database servers that is returned includes only local database servers: <ul style="list-style-type: none"> <li>• <b>TRUE</b>—Return only local database servers.</li> <li>• <b>FALSE</b>—Return all database servers.</li> </ul> |

## Return Values

Returns a list of the database servers available on the network for database technologies specified for a connection.

# SQLRTInitialize

**Project** ▪ This information applies to InstallScript projects.

The **SQLRTInitialize2** function supersedes the **SQLRTInitialize** function.

If the **SQLRTInitialize** function is used, it must be the first function called in SQLRT. **SQLRTInitialize** loads the SQLRT.dll and initializes it using the settings file.

## Syntax

```
SQLRTInitialize( szSettingsFile );
```

## Parameters

**Table 225** ■ SQLRTInitialize Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSettingsFile</b> | <p>Specifies the path to the SQLRT.ini file. The following path should be specified for this parameter:</p> <p><b>SUPPORTDIR ^ "SQLRT.ini"</b></p> <p>The SQLRT.ini file should not be modified; otherwise, unexpected behavior may occur at run time. InstallShield creates this file based on SQL settings that are entered in the SQL Scripts view.</p> |

## Return Values

None

# SQLRTInitialize2

**Project** ■ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SQLRTInitialize2** must be the first function called in the SQL run time. **SQLRTInitialize2** loads the SQLRT.dll file for InstallScript projects and the ISSQLSRV.dll file for InstallScript MSI projects, and it uses the settings file to initialize the .dll file.

**Note** ■ If you want to call any built-in SQL-related function before the OnSQLServerInitialize event handler is called in an InstallScript project or the OnSQLLogin event handler is called in an InstallScript MSI project, call the **SQLRTInitialize2** function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTInitialize2 ();
```

## Parameters

**SQLRTInitialize2** takes no parameters.

## Return Values

None

# SQLRTPutConnectionAuthentication

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SQLRTPutConnectionAuthentication** function sets the default SQL Server connection authentication type.

**Note** ▪ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an InstallScript project or the *OnSQLLogin* event handler is called in an InstallScript MSI project, call the [SQLRTInitialize2](#) function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTPutConnectionAuthentication( szConnection, bWinLogin );
```

## Parameters

**Table 226** ▪ SQLRTPutConnectionAuthentication Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b> | Specifies the name of the connection that you created in the SQL Scripts view.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>bWinLogin</b>    | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |

## Return Values

None

# SQLRTPutConnectionInfo

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLRTPutConnectionInfo2** function supersedes the **SQLRTPutConnectionInfo** function.

The **SQLRTPutConnectionInfo** function sets the connection information (the default server, default user name, and default password). This is useful in situations when you need to recall what an end user previously entered, like use of the Back button.

**Note** ▪ The **SQLRTPutConnectionInfo** function uses `SQLRT.dll` in *InstallScript* projects and `ISSQLSRV.dll` in *InstallScript MSI* projects; therefore, it can be called only after **SQLRTInitialize2** has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTPutConnectionInfo( szConnection, szServer, szUser, szPassword );
```

## Parameters

**Table 227** ▪ SQLRTPutConnectionInfo Parameters

| Parameter           | Description                                            |
|---------------------|--------------------------------------------------------|
| <b>szConnection</b> | Specifies the SQL Server connection.                   |
| <b>szServer</b>     | Specifies the SQL Server.                              |
| <b>szUser</b>       | Specifies the SQL Server login information.            |
| <b>szPassword</b>   | Specifies the password associated with a user account. |

## Return Values

**Table 228** ▪ SQLRTPutConnectionInfo Return Values

| Return Value                           | Description                                       |
|----------------------------------------|---------------------------------------------------|
| <b>&gt;=ISERR_SUCCESS</b>              | This function was able to establish a connection. |
| <b>&lt;ISERR_SUCCESS</b>               | This function failed to establish a connection.   |
| <b>SQL_ERROR_NOT_INITIALIZED (-10)</b> | SQLRT.dll is not loaded.                          |

# SQLRTPutConnectionInfo2

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLRTPutConnectionInfo2** function sets the connection information (the default server, default database catalog, default user name, and default password). This is useful in situations when you need to recall what an end user previously entered, like use of the Back button.

**Note** ▪ The **SQLRTPutConnectionInfo2** function uses `SQLRT.dll` for *InstallScript* projects and `ISSQLSRV.dll` for *InstallScript MSI* projects; therefore, it can be called only after [SQLRTInitialize2](#) has already been called. To learn more, see [Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects](#).

## Syntax

```
SQLRTPutConnectionInfo2( szConnection, szServer, svDBCatalog, szUser, szPassword );
```

## Parameters

**Table 229** ▪ SQLRTPutConnectionInfo2 Parameters

| Parameter           | Description                                            |
|---------------------|--------------------------------------------------------|
| <b>szConnection</b> | Specifies the SQL Server connection.                   |
| <b>szServer</b>     | Specifies the SQL Server.                              |
| <b>svDBCatalog</b>  | Specifies the name of the SQL database catalog.        |
| <b>szUser</b>       | Specifies the SQL Server login information.            |
| <b>szPassword</b>   | Specifies the password associated with a user account. |

## Return Values

**Table 230** ▪ SQLRTPutConnectionInfo2 Return Values

| Return Value                           | Description                                       |
|----------------------------------------|---------------------------------------------------|
| <b>&gt;=ISERR_SUCCESS</b>              | This function was able to establish a connection. |
| <b>&lt;ISERR_SUCCESS</b>               | This function failed to establish a connection.   |
| <b>SQL_ERROR_NOT_INITIALIZED (-10)</b> | SQLRT.dll is not loaded.                          |

# SQLRTServerValidate

**Project** ▪ This information applies to *InstallScript MSI* projects.

The **SQLRTServerValidate** function tests connections specified in the installation.

**Note** ▪ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an *InstallScript* project or the *OnSQLLogin* event handler is called in an *InstallScript MSI* project, call the *SQLRTInitialize2* function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTServerValidate\(\ hInstall );
```

## Parameters

**Table 231** ▪ SQLRTServerValidate Parameters

| Parameter       | Description                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hInstall</b> | Specifies the handle to the installation.<br><br>When <code>IS_SQLSERVER_CONNECTIONS_TO_VALIDATE</code> is specified, only the connections that are specified as the value of that Windows Installer property are tested. |

## Return Values

**Table 232** ▪ SQLRTServerValidate Return Values

| Return Value                     | Description                                       |
|----------------------------------|---------------------------------------------------|
| <b>=ISERR_SUCCESS</b>            | This function was able to establish a connection. |
| <b>SQL_ERROR_NOT_INITIALIZED</b> | ISSQLSRV.dll is not loaded.                       |

## Additional Information

The result is used to set the value of the `IS_SQLSERVER_STATUS` property. Possible values are listed in the following table.

**Table 233** ▪ IS\_SQLSERVER\_STATUS Property Values

| Return Value | Description                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>     | The function was able to establish one or more connections.                                                                     |
| <b>1</b>     | The function failed to establish a connection.                                                                                  |
| <b>2</b>     | The function was able to establish a connection, but it failed to retrieve the product version from the target database server. |

**Table 233** ■ IS\_SQLSERVER\_STATUS Property Values (cont.)

| Return Value | Description                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>3</b>     | The function was able to establish a connection, but the version requirement was not met.                                                                                                                                  |
| <b>4</b>     | The function was able to establish a connection, but MSDE or the Express version was not allowed.                                                                                                                          |
| <b>5</b>     | The function was able to establish a connection, but it failed to retrieve the schema version from the target database catalog.                                                                                            |
| <b>6</b>     | The function was able to establish a connection, but it failed to set the schema version to the target database catalog.                                                                                                   |
| <b>7</b>     | The function could not find the specified ODBC driver.                                                                                                                                                                     |
| <b>8</b>     | The function was able to establish a connection to the default database catalog, but it failed to create the target database catalog (when <b>Create Catalog If Absent</b> check box in the SQL Scripts view is selected). |
| <b>9</b>     | The function was able to establish a connection to the default database catalog, but it failed to connect to the target database catalog.                                                                                  |
| <b>10</b>    | The function could not find a valid record in ISSQLDBMetaData table.                                                                                                                                                       |

## SQLRTSetBrowseOption

**Project** ■ This information applies to InstallScript projects.

The **SQLRTSetBrowseOption** function lets you specify whether the SQL Server browse combo box and list box controls show local servers, remote servers, server aliases, or a combination of these types.

**Note** ■ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an InstallScript project or the *OnSQLLogin* event handler is called in an InstallScript MSI project, call the [SQLRTInitialize2](#) function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

### Syntax

```
SQLRTSetBrowseOption( nBrowseOption );
```

## Parameters

**Table 234** ▪ SQLRTSetBrowseOption Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nBrowseOption</b> | <p>Pass one or more of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>SQL_BROWSE_ALL (0)</b>—Show all of the available SQL Servers. Specifying this constant has the same effect as selecting the SQL_BROWSE_LOCAL, SQL_BROWSE_REMOTE, and SQL_BROWSE_ALIAS constants.</li> <li>• <b>SQL_BROWSE_LOCAL (1)</b>—Show local SQL Servers.</li> <li>• <b>SQL_BROWSE_REMOTE (2)</b>—Show remote SQL Servers.</li> <li>• <b>SQL_BROWSE_ALIAS (4)</b>—Show SQL Server aliases.</li> </ul> <p>You can specify multiple browse options by combining constants with the bitwise OR operator ( ).</p> |

## Return Values

None

# SQLRTTestConnection

**Project** ▪ This information applies to InstallScript MSI projects.

The **SQLRTTestConnection2** function supersedes the **SQLRTTestConnection** function.

The **SQLRTTestConnection** function tests all of the connections specified in the installation using the specified credential.

**Note** ▪ If you want to call any built-in SQL-related function before the *OnSQLServerInitialize* event handler is called in an InstallScript project or the *OnSQLLogin* event handler is called in an InstallScript MSI project, call the **SQLRTInitialize2** function first. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

## Syntax

```
SQLRTTestConnection( szServer, szDB, szUserName, szPassword, bTrust );
```

## Parameters

**Table 235** ▪ SQLRTTestConnection Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szServer</b>   | Specifies the SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>szDB</b>       | Specifies the catalog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szUserName</b> | Specifies the SQL Server login information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szPassword</b> | Specifies the password associated with a user account.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>bTrust</b>     | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |

## Return Values

**Table 236** ▪ SQLRTTestConnection Return Values

| Return Value                     | Description                                       |
|----------------------------------|---------------------------------------------------|
| <b>=ISERR_SUCCESS</b>            | This function was able to establish a connection. |
| <b>SQL_ERROR_NOT_INITIALIZED</b> | ISSQLSRV.dll is not loaded.                       |

## Additional Information

The result is used to set the value of the IS\_SQLSERVER\_STATUS property. Possible values are listed in the following table.

**Table 237** ▪ IS\_SQLSERVER\_STATUS Property Values

| Return Value | Description                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>     | The function was able to establish one or more connections.                                                                     |
| <b>1</b>     | The function failed to establish a connection.                                                                                  |
| <b>2</b>     | The function was able to establish a connection, but it failed to retrieve the product version from the target database server. |
| <b>3</b>     | The function was able to establish a connection, but the version requirement was not met.                                       |

**Table 237** ■ IS\_SQLSERVER\_STATUS Property Values (cont.)

| Return Value | Description                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>4</b>     | The function was able to establish a connection, but MSDE or the Express version was not allowed.                                                                                                                          |
| <b>5</b>     | The function was able to establish a connection, but it failed to retrieve the schema version from the target database catalog.                                                                                            |
| <b>6</b>     | The function was able to establish a connection, but it failed to set the schema version to the target database catalog.                                                                                                   |
| <b>7</b>     | The function could not find the specified ODBC driver.                                                                                                                                                                     |
| <b>8</b>     | The function was able to establish a connection to the default database catalog, but it failed to create the target database catalog (when <b>Create Catalog If Absent</b> check box in the SQL Scripts view is selected). |
| <b>9</b>     | The function was able to establish a connection to the default database catalog, but it failed to connect to the target database catalog.                                                                                  |
| <b>10</b>    | The function could not find a valid record in ISSQLDBMetaData table.                                                                                                                                                       |

## SQLRTTestConnection2

**Project** ■ This information applies to InstallScript MSI projects.

The **SQLRTTestConnection2** function establishes a connection.

**Note** ■ The **SQLRTTestConnection2** function uses ISSQLSRV.dll; therefore, it can be called only after **SQLRTInitialize2** has already been called. To learn more, see *Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects*.

### Syntax

```
SQLRTTestConnection2( szConnection, szServer, szDB, szUserName, szPassword, bTrust );
```

## Parameters

**Table 238** ▪ SQLRTTestConnection2 Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b> | Specifies the SQL Server connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>szServer</b>     | Specifies the SQL Server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>svDB</b>         | Specifies the catalog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>szUser</b>       | Specifies the SQL Server login information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>szPassword</b>   | Specifies the password associated with a user account.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>bTrust</b>       | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |

## Return Values

**Table 239** ▪ SQLRTTestConnection2 Return Values

| Return Value                     | Description                                       |
|----------------------------------|---------------------------------------------------|
| <b>=ISERR_SUCCESS</b>            | This function was able to establish a connection. |
| <b>SQL_ERROR_NOT_INITIALIZED</b> | ISSQLSRV.dll is not loaded.                       |

## Additional Information

The result is used to set the value of the `IS_SQLSERVER_STATUS` property. Possible values are listed in the following table.

**Table 240** ▪ IS\_SQLSERVER\_STATUS Property Values

| Return Value | Description                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>     | The function was able to establish one or more connections.                                                                     |
| <b>1</b>     | The function failed to establish a connection.                                                                                  |
| <b>2</b>     | The function was able to establish a connection, but it failed to retrieve the product version from the target database server. |

**Table 240** ■ IS\_SQLSERVER\_STATUS Property Values (cont.)

| Return Value | Description                                                                                                                                                                                                                |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>3</b>     | The function was able to establish a connection, but the version requirement was not met.                                                                                                                                  |
| <b>4</b>     | The function was able to establish a connection, but MSDE or the Express version was not allowed.                                                                                                                          |
| <b>5</b>     | The function was able to establish a connection, but it failed to retrieve the schema version from the target database catalog.                                                                                            |
| <b>6</b>     | The function was able to establish a connection, but it failed to set the schema version to the target database catalog.                                                                                                   |
| <b>7</b>     | The function could not find the specified ODBC driver.                                                                                                                                                                     |
| <b>8</b>     | The function was able to establish a connection to the default database catalog, but it failed to create the target database catalog (when <b>Create Catalog If Absent</b> check box in the SQL Scripts view is selected). |
| <b>9</b>     | The function was able to establish a connection to the default database catalog, but it failed to connect to the target database catalog.                                                                                  |
| <b>10</b>    | The function could not find a valid record in ISSQLDBMetaData table.                                                                                                                                                       |

## SQLServerLogin

**Project** ■ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLServerLogin** function creates a dialog that is used by the script to specify SQL login credentials. These credentials include the login ID and password.

This function is in the SQLRT.obl file for InstallScript projects, and in the SQLCONV.obl file for InstallScript MSI projects. If you are using the SQL Scripts view in InstallShield, the appropriate file is automatically added to your linker settings. However, if you are not using this view, add the appropriate file to your linker settings: On the Build menu, click Settings, and then add it to the Libraries (.obl) box.

### Syntax

```
SQLServerLogin( szMsg, svUser, svPassword );
```

## Parameters

**Table 241** ▪ SQLServerLogin Parameters

| Parameter         | Description                                                                                                                                                                                                                                                                                          |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b>      | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                                                                                                      |
| <b>svUser</b>     | Specifies the default string to display in the Login ID edit box. Once the dialog function returns, this parameter contains the Login ID that the end user entered in the edit box. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.     |
| <b>svPassword</b> | Specifies the default string to display in the Password edit field. Once the dialog function returns, this parameter contains the password that the end user entered in the edit field. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials. |

## Return Values

**Table 242** ▪ SQLServerLogin Return Values

| Return Value              | Description                            |
|---------------------------|----------------------------------------|
| <b>NEXT</b>               | The end user selected the Next button. |
| <b>BACK</b>               | The end user selected the Back button. |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.     |

# SQLServerSelect

**Project** ▪ This information applies to the following project types:

- InstallScript
- InstallScript MSI

The **SQLServerSelect** function creates a dialog that lets the end user select a database server.

This function is in the SQLRT.obl file for InstallScript projects, and in the SQLCONV.obl file for InstallScript MSI projects. If you are using the SQL Scripts view in InstallShield, the appropriate file is automatically added to your linker settings. However, if you are not using this view, add the appropriate file to your linker settings: On the Build menu, click Settings, and then add it to the Libraries (.obl) box.

## Syntax

```
SQLServerSelect( szMsg, svServer );
```

## Parameters

**Table 243** ▪ SQLServerSelect Parameters

| Parameter       | Description                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szMsg</b>    | Specifies the message to display in the dialog. To display the default instructions for this dialog, pass a null string ("") in this parameter.                                                                     |
| <b>szServer</b> | Specifies the default server to initially display in the Server combo box. Once the dialog function returns, this parameter contains the server name that the end user selected or entered in the Server combo box. |

## Return Values

**Table 244** ▪ SQLServerSelect Return Values

| Return Value              | Description                            |
|---------------------------|----------------------------------------|
| <b>NEXT</b>               | The end user selected the Next button. |
| <b>BACK</b>               | The end user selected the Back button. |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.     |

# SQLServerSelectLogin

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The [SQLServerSelectLogin2](#) function supersedes the **SQLServerSelectLogin** function.

The **SQLServerSelectLogin** function creates a dialog that is used by the default script. It allows the targeted end user to specify which SQL Server is to be used for the current connection, along with which login credential should be used. When the dialog is displayed, a combo box shows a list of SQL Servers accessed through DSNs. A Browse button is available to bring up a list of all SQL Servers available on the network or the end user can type a server name into the combo box. Also, the end user has the option to use Windows login credentials or enter a SQL Server login ID and password.

This function is in the SQLRT.ob1 file for InstallScript projects, and in the SQLCONV.ob1 file for InstallScript MSI projects. If you are using the SQL Scripts view in InstallShield, the appropriate file is automatically added to your linker settings. However, if you are not using this view, add the appropriate file to your linker settings: On the Build menu, click Settings, and then add it to the Libraries (.obl) box.

## Syntax

```
SQLServerSelectLogin (byref string svServer, byref string svUser, byref string svPassword, byref BOOL  
    bvWindowsLogin );
```

## Parameters

**Table 245** ▪ SQLServerSelectLogin Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szServer</b>       | <p>Specifies the default server to initially display in the Server combo box. Once the dialog function returns, this parameter contains the server name the end user selected or entered in the Server combo box.</p> <p>This parameter supports alias names for SQL Server database connections.</p>                                                                                                                                                                                                                         |
| <b>svUser</b>         | <p>Specifies the default string to display in the Login ID edit box. Once the dialog function returns, this parameter contains the Login ID that the end user entered in the edit box. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.</p>                                                                                                                                                                                                                       |
| <b>svPassword</b>     | <p>Specifies the default string to display in the Password edit field. Once the dialog function returns, this parameter contains the Password that the end user entered in the edit field. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.</p>                                                                                                                                                                                                                   |
| <b>bvWindowsLogin</b> | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |

## Return Values

**Table 246** ▪ SQLServerSelectLogin Return Values

| Return Value              | Description                            |
|---------------------------|----------------------------------------|
| <b>NEXT</b>               | The end user selected the Next button. |
| <b>BACK</b>               | The end user selected the Back button. |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.     |

# SQLServerSelectLogin2

**Project** ▪ This information applies to the following project types:

- *InstallScript*

- *InstallScript MSI*

The **SQLServerSelectLogin2** function creates a login dialog that is used by the default script. It lets the targeted end user specify which SQL Server should be used for the current connection, as well as which login credential should be used. The dialog displays a combo box that contains a list of SQL Servers accessed through DSNs. The end user can type a server name in the combo box or click the Browse button next to the Server Name combo box; clicking this button displays a list of all SQL Servers that are available on the network. The end user has the option to use Windows login credentials or enter a SQL Server login ID and password.

When `bShowCxnName` is set to `TRUE`, the dialog shows the connection name that is associated with the connection information. In addition, when `bShowDBCatalog` is set to `TRUE`, the dialog allows the end user to specify which database catalog should be used for the current connection. The end user can type a catalog name in the edit box or click the Browse button next to the name of database catalog edit box. Clicking the Browse button displays a list of all database catalogs that are available on the specified database server.

## Syntax

```
SQLServerSelectLogin2( szConnection, svServer, svUser, svPassword, bvWindowsLogin, svCatalog,  
    bShowCxnName, bShowDBCatalog );
```

## Parameters

**Table 247** ▪ SQLServerSelectLogin2 Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b>   | Specifies the SQL Server connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>szServer</b>       | <p>Specifies the default server to initially display in the Server combo box. Once the dialog function returns, this parameter contains the server name the end user selected or entered in the Server combo box.</p> <p>This parameter supports alias names for SQL Server database connections.</p>                                                                                                                                                                                                                         |
| <b>svUser</b>         | Specifies the default string to display in the Login ID edit box. Once the dialog function returns, this parameter contains the Login ID that the end user entered in the edit box. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.                                                                                                                                                                                                                              |
| <b>svPassword</b>     | Specifies the default string to display in the Password edit field. Once the dialog function returns, this parameter contains the Password that the end user entered in the edit field. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.                                                                                                                                                                                                                          |
| <b>bvWindowsLogin</b> | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |
| <b>svCatalog</b>      | Specifies the name of the database catalog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>bShowCxnName</b>   | <p>Specifies whether the dialog should show the name of the connection that is associated with the connection information. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Show the name of the connection.</li> <li>● <b>FALSE</b>—Do not show the name of the connection.</li> </ul>                                                                                                                                                             |

**Table 247** ■ SQLServerSelectLogin2 Parameters (cont.)

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bShowDBCatalog</b> | <p>Specifies whether the end user can select which database catalog should to be used for the current connection. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>TRUE</b>—Allow the end user to select which database catalog should to be used for the current connection. The end user can type a catalog name in the edit box or click the Browse button next to the name of database catalog edit box. Clicking this Browse button displays a list of all database catalogs that are available on the specified database server.</li> <li>● <b>FALSE</b>—Do not allow the end user to select which database catalog should to be used for the current connection.</li> </ul> |

## Return Values

**Table 248** ■ SQLServerSelectLogin2 Return Values

| Return Value              | Description                            |
|---------------------------|----------------------------------------|
| <b>NEXT</b>               | The end user selected the Next button. |
| <b>BACK</b>               | The end user selected the Back button. |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.     |

# SQLServerSelectLoginEx

**Project** ■ This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

The **SQLServerSelectLogin2** function supersedes the **SQLServerSelectLoginEx** function.

The **SQLServerSelectLoginEx** function creates a login dialog that is used by the default script. It lets the targeted end user specify which SQL Server should be used for the current connection, as well as which login credential should be used. The dialog also shows the connection name that is associated with the connection information.

The dialog displays a combo box that contains a list of SQL Servers accessed through DSNs. The end user can type a server name in the combo box or click the Browse button next to the Server Name combo box; clicking this button displays a list of all SQL Servers that are available on the network. The end user has the option to use Windows login credentials or enter a SQL Server login ID and password.

## Syntax

```
SQLServerSelectLoginEx (byval string szConnection, byref string svServer, byref string svUser,  
    byref string svPassword, byref BOOL bvWindowsLogin)
```

## Parameters

**Table 249** ▪ SQLServerSelectLoginEx Parameters

| Parameter             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szConnection</b>   | Specifies the SQL Server connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>szServer</b>       | <p>Specifies the default server to initially display in the Server combo box. Once the dialog function returns, this parameter contains the server name the end user selected or entered in the Server combo box.</p> <p>This parameter supports alias names for SQL Server database connections.</p>                                                                                                                                                                                                                         |
| <b>svUser</b>         | Specifies the default string to display in the Login ID edit box. Once the dialog function returns, this parameter contains the Login ID that the end user entered in the edit box. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.                                                                                                                                                                                                                              |
| <b>svPassword</b>     | Specifies the default string to display in the Password edit field. Once the dialog function returns, this parameter contains the Password that the end user entered in the edit field. This information is only pertinent if the end user selected to use SQL Login instead of Windows credentials.                                                                                                                                                                                                                          |
| <b>bvWindowsLogin</b> | <p>Specifies the initial state of the radio buttons specifying login using Windows credentials vs. SQL Server credentials. When this is TRUE, the password and login ID fields are disabled. When it is FALSE, indicating that SQL Server credentials are to be used, the password and login fields are enabled.</p> <p>Once the function returns, this parameter contains TRUE if the Windows credentials radio button was specified by the end user and FALSE if the SQL Server credentials radio was selected instead.</p> |

## Return Values

**Table 250** ▪ SQLServerSelectLoginEx Return Values

| Return Value              | Description                            |
|---------------------------|----------------------------------------|
| <b>NEXT</b>               | The end user selected the Next button. |
| <b>BACK</b>               | The end user selected the Back button. |
| <b>&lt; ISERR_SUCCESS</b> | The dialog could not be displayed.     |

## StatusUpdate

The **StatusUpdate** function enables or disables the link between file transfer operations and the progress indicator of the status bar. When **bLink** is ON, the link is enabled and **nFinalPercent** specifies a final percentage to be displayed at the end of the next file transfer. During that file transfer, the status bar is updated smoothly from

its current value to the value specified by `nFinalPercent`. When `bLink` is OFF, the link is disabled and the progress indicator of the status bar is not updated automatically during subsequent file transfers.

This function works by computing the total number of bytes to be transferred by any of the file transfer functions. It then computes how often it will increment the progress bar starting from its current location to the maximum value in `nFinalPercent`.

The `StatusUpdate` function does not work with the functions `VerUpdateFile` and `VerSearchAndUpdateFile`. When calling those functions, you should disable the status bar or update it manually.

To set the status bar to an initial percentage, call `SetStatusWindow` before calling `StatusUpdate`.

---

**Tip** ▪ If the status bar is enabled during file transfer, call `StatusUpdate` before each call to `CopyFile` or `XCopyFile`). Before calling `FeatureMoveData` to transfer files, call `StatusUpdate` with the parameters `ON` and `100`. This sets the status bar to update smoothly to 100% during the file transfer stage of the setup.

## Syntax

```
StatusUpdate ( bLink, nFinalPercent );
```

## Parameters

**Table 251** ▪ StatusUpdate Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bLink</b>         | <p>Specifies whether to enable or disable the link between file transfer operations and the progress indicator of the status bar. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>● <b>ON</b>—Specifies that the progress indicator of the status bar should be linked to file transfer operations.</li> <li>● <b>OFF</b>—Specifies that link between file transfer operations and the progress indicator of the status bar should be disabled. The link remains disabled until it is reestablished by a subsequent call to StatusUpdate with bLink set to ON.</li> </ul> <p></p> <p><b>Note</b> ▪ The status bar can be updated manually by calling <i>SetStatusWindow</i>.</p> |
| <b>nFinalPercent</b> | <p>Specifies the final percentage value that the progress indicator of the status bar should reach at the end of the next file transfer operation if bLink is ON. If the value passed in nFinalPercent is less than the current value in the progress indicator of the status bar, the progress indicator will not change. When bLink is OFF, this parameter is ignored.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Return Values

**Table 252** ▪ StatusUpdate Return Values

| Return Value  | Description                                     |
|---------------|-------------------------------------------------|
| <b>0</b>      | Indicates that the function was successful.     |
| <b>&lt; 0</b> | Indicates that the function was not successful. |

## StatusUpdate Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
```

```

* Demonstrates the StatusUpdate function.
*
* This script copies all files from a source directory to a
* target directory. StatusUpdate is called to set the limit
* of the progress bar and to regulate the progress indicator
* as the files are copied.
*
* Note: Before running this script, create the directories
*       referenced by SOURCE_DIR and TARGET_DIR and create two
*       or more files in SOURCE_DIR.
*
\*-----*/

#define SOURCE_DIR "C:\\ISExempl\\Source"
#define TARGET_DIR "C:\\ISExempl\\Target";

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_StatusUpdate(HWND);

function ExFn_StatusUpdate(hMSI)
begin

    // Enable the progress bar.
    Enable(STATUS);

    // Set the limit of the progress bar to 99% completion.
    StatusUpdate (ON, 99);

    // Copy the files.
    if (XCopyFile (SOURCE_DIR ^ ".*", TARGET_DIR ^ ".*", COMP_NORMAL) < 0 ) then
        MessageBox ("An error occurred while copying files.",SEVERE);
    endif;

    // Display a message; do not change the progress bar.
    SetStatusWindow (-1, "File Copying completed at 99%.");
    Delay (3);

    // Set the progress bar to 100% and displays a message.
    SetStatusWindow (100, "StatusUpdate example completed, now exiting...");
    Delay (3);

end;

```

## StrAddLastSlash

The **StrAddLastSlash** function adds a trailing backslash to a path specification if it does not already have one.

### Syntax

```
StrAddLastSlash ( svPath );
```

## Parameters

**Table 253** ▪ StrAddLastSlash Parameters

| Parameter     | Description                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svPath</b> | Specifies a string whose value must be a path specification; it returns the path with a trailing backslash. Note that if the path includes a trailing backslash, it is returned unchanged. |

## Return Values

**Table 254** ▪ StrAddLastSlash Return Values

| Return Value               | Description                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully added the trailing backslash or that the path contains a trailing backslash. |

# StrCompare

The **StrCompare** function compares two strings. The comparison is not case-sensitive.

## Syntax

```
StrCompare ( szStringA, szStringB );
```

## Parameters

**Table 255** ▪ StrCompare Parameters

| Parameter | Description                             |
|-----------|-----------------------------------------|
| szStringA | Specifies the first string to compare.  |
| szStringB | Specifies the second string to compare. |

## Return Values

**Table 256** ▪ StrCompare Return Values

| Return Value | Description                                                                              |
|--------------|------------------------------------------------------------------------------------------|
| < 0          | Indicates that the string in szStringA has a lower value than the string in szStringB.   |
| 0            | Indicates that the two strings are equal.                                                |
| > 0          | Indicates that the string in szStringA has a greater value than the string in szStringB. |

## Additional Information

The **StrCompare** function compares the strings by checking the first character in each string, the second character in each string, and so on—until it finds an inequality or reaches the ends of the strings.

The language driver for the language that you select determines which string is greater or if the strings are the same. If you do not use a language driver, Windows uses an internal function. With a double-byte character set (DBCS) version of Windows, this function can compare two DBCS strings.

## StrCompare Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the StrCompare function.
*
* StrCompare is called to compare two strings. The result of
* the comparison is displayed in a message box.
*
\*-----*/

#define TITLE_TEXT "StrCompare Example"
```

```

#define MSG_TEXT    "Please enter two strings to compare:"
#define FIELD_A     "String A:"
#define FIELD_B     "String B:"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_StrCompare(HWND);

function ExFn_StrCompare(hMSI)
    STRING svStringA, svStringB;
    NUMBER nResult;
begin

    // Get two strings from the user.
    SdShowDlgEdit2 (TITLE_TEXT, MSG_TEXT, FIELD_A, FIELD_B, svStringA, svStringB);

    // Compare the strings.
    nResult = StrCompare (svStringA, svStringB);

    // Display the result.
    if (nResult = 0) then
        MessageBox (svStringA + " and " + svStringB + " are equal.", INFORMATION);
    elseif (nResult < 0) then
        MessageBox (svStringB + " is greater than " + svStringA, INFORMATION);
    else
        MessageBox (svStringA + " is greater value than " + svStringB, INFORMATION);
    endif;

end;

```

## StrConvertSizeUnit

The **StrConvertSizeUnit** function returns the appropriate display string for the InstallScript size unit constant that is specified.

### Syntax

```
StrConvertSizeUnit (byval string nUnit);
```

## Parameters

**Table 257** ▪ StrConvertSizeUnit Parameters

| Parameter | Description                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nUnit     | Specify the unit constant that you want to be converted to a UI string. The following constants are supported: <ul style="list-style-type: none"> <li>• BYTES</li> <li>• KBYTES</li> <li>• MBYTES</li> <li>• GBYTES</li> <li>• TBYTES</li> </ul> |

## Return Values

**Table 258** ▪ StrConvertSizeUnit Return Values

| Return Value      | Description                                 |
|-------------------|---------------------------------------------|
| <b>bytes</b>      | The function converted the BYTES constant.  |
| <b>KB</b>         | The function converted the KBYTES constant. |
| <b>MB</b>         | The function converted the MBYTES constant. |
| <b>GB</b>         | The function converted the GBYTES constant. |
| <b>TB</b>         | The function converted the TBYTES constant. |
| <b>Null ("" )</b> | The function failed to convert nUnit.       |

# StreamFileFromBinary

The **StreamFileFromBinary** function streams a binary key with a file.

## Syntax

```
StreamFileFromBinary ( hInstall(HWND), svObjectBinaryKey, szFileName );
```

## Parameters

**Table 259** ▪ StreamFileFromBinary Parameters

| Parameter                | Description                                               |
|--------------------------|-----------------------------------------------------------|
| <b>hInstall (HWND)</b>   | Provides a handle to the currently running application.   |
| <b>svObjectBinaryKey</b> | Indicates the key to be streamed out of the binary table. |
| <b>szFileName</b>        | Indicates the full path to the extracted file.            |

## Return Values

**Table 260** ▪ StreamFileFromBinary Return Values

| Return Value | Description                                                      |
|--------------|------------------------------------------------------------------|
| <b>0</b>     | The function successfully streamed the binary key with the file. |
| <b>-1</b>    | The function failed to stream the binary key with the file.      |

# StrFind

The **StrFind** function determines whether the string passed in the parameter `szFindMe` is found within the string passed in the parameter `szString`. If `szFindMe` is found in `szString`, **StrFind** returns the position within `szString` of the first character of `szFindMe`. (Note that the position of the first character in `szString` is zero.) This function is not case-sensitive and can be used only to find the first occurrence of `szFindMe` in `szString`.

StrFind calls the following:

```
StrFindEx(szString, szFindMe, 0);
```

For more information about parameters and return values for **StrFind**, see [StrFindEx](#).

## StrFind Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the StrFind function.
```

```

*
* StrFind is called to search for a substring within a string.
* If successful, StrFind returns the location of the substring.
*
\*-----*/

#define TITLE_TEXT "StrFind Example";

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_StrFind(HWND);

function ExFn_StrFind(hMSI)
    STRING szString, szFindMe, szTitle, szMsg;
    NUMBER nLocation;
begin

    // Set up parameters for call to StrFind.
    szString = "This is a sample string to be searched.";
    szFindMe = "Sample String";

    // Find the substring specified by szFindMe.
    nLocation = StrFind (szString, szFindMe);

    // Display the location of the text if it was found.
    if (nLocation < 0) then
        MessageBox (szFindMe + " not found in " + szString + ".", WARNING);
    else
        szMsg = "'%s' starts at byte %d of\n'%s'";
        sprintfBox (INFORMATION, szTitle, szMsg, szFindMe, nLocation, szString);
    endif;

end;

```

## StrFindEx

The **StrFindEx** function determines whether the string passed in the parameter `szFindMe` is found within the string passed in the parameter `szString`; the function begins its search at the location specified by `nStart`. If `szFindMe` is found, `StrFind` returns the position within `szString` of the first character of `szFindMe`. This function is not case-sensitive and can be used only to find the first occurrence of `szFindMe` in `szString`.

### Syntax

```
StrFindEx ( szString, szFindMe, nStart );
```

## Parameters

**Table 261** ▪ StrFindEx Parameters

| Parameter       | Description                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szString</b> | Specifies the string to search.                                                                                                                                                   |
| <b>szFindMe</b> | Specifies the string to find in szString.                                                                                                                                         |
| <b>nStart</b>   | Specifies an offset into szString that identifies the character at which to begin the search for szFindMe. Note that the position of the first character in szString is 0 (zero). |

## Return Values

**Table 262** ▪ StrFindEx Return Values

| Return Value  | Description                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>X</b>      | If szString contains szFindMe, X is the numeric position of the first character in szFindMe. The first character in szString is in position 0 (zero). |
| <b>&lt; 0</b> | Indicates szString does not contain szFindMe.                                                                                                         |

## Additional Information

In the example below, StrFind will return the value 19.

```
nStartPos = StrFind("Scripting means having fun","ing",7);
```

If you need only a TRUE or FALSE return value indicating whether one string contains another string, (that is, if the location if the substring is unimportant), use the string find operator (%) as shown below:

```
if (szString % szFindMe) then ...
```

You can use the string find operator (%) only in Boolean expressions that are resolved in if statements. You cannot use it in repeat statements or while statements.

# StrGetTokens

The **StrGetTokens** function extracts substrings (tokens) from the string specified by szString and places them into the list specified by listID. The substrings in szString must be delimited—separated from one another—by one or more of the characters specified by szDelimiterSet.

For example, if you call StrGetTokens with the string "One;Two;Three;Four;Five" as the second parameter and ";" as the third parameter, listID will be returned with five strings: "One", "Two", "Three", "Four", and "Five". Use the list functions, such as ListGetFirstString and ListGetNextString to access each token in the list.

**Note** ▪ If the first (or last) character of *szString* matches a character in *szDelimiterSet*, a null string ("" ) is not inserted in the list as the first (or last) element. Instead, the characters between the first and second (or last and next to last) delimiters are inserted in the list as the first (or last) element.

Syntax

```
StrGetTokens ( listID, szString, szDelimiterSet );
```

Parameters

Table 263 ▪ StrGetTokens Parameters

| Parameter                                                                                                                                                                                                                            | Description                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| listID                                                                                                                                                                                                                               | Returns a list of tokens. The string list identified by listID must already have been initialized by a call to <a href="#">ListCreate</a> .                                                                                                                                      |
| szString                                                                                                                                                                                                                             | Specifies the string to be parsed.                                                                                                                                                                                                                                               |
| szDelimiterSet                                                                                                                                                                                                                       | Specifies a set of one or more delimiters. Each delimiter is one character (1 byte). If you pass a null string ("" ) in this parameter, the function searches for null characters as the delimiters. This is useful if you are using the <a href="#">GetProfString</a> function. |
| <div></div> <p><b>Note</b> ▪ When a space is specified as the delimiter, <i>StrGetTokens</i> treats consecutive spaces as a single delimiter.</p> |                                                                                                                                                                                                                                                                                  |

Return Values

Table 264 ▪ StrGetTokens Return Values

| Return Value | Description                                                                                                    |
|--------------|----------------------------------------------------------------------------------------------------------------|
| 0            | Indicates that the function successfully separated the string and inserted the tokens into the specified list. |
| < 0          | Indicates that the function was unable to separate the string and insert the tokens into the list.             |

StrGetTokens Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the StrGetTokens function.
*
* First, the value of a key is retrieved from an initialization
* file. The value returned is a search path. Then
* StrGetTokens is called to build a list of the paths found in
* the search path. Finally, the paths are displayed.
*
* In order for this script to run correctly, you must create
* an initialization (text) file and add the following lines to
* it:
*
* [Test Section]
* searchpath=C:\Windows;C:\Windows\System;C:\Windows\Command
*
* Then set the constant EXAMPLE_INI to the fully qualified name
* of that file.
*
\*-----*/

#define FILE_NAME    "C:\\ISExempl.ini"
#define SECTION_NAME "Test Section"
#define KEY_NAME     "searchpath"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_StrGetTokens(HWND);

function ExFn_StrGetTokens(hMSI)
    LIST listID;
    STRING svSearchPath;
    STRING szTitle, szMsg;
begin

    // Get the value of the specified key from the specified section
    // of the initialization file.
    if GetProfString (FILE_NAME, SECTION_NAME, KEY_NAME, svSearchPath) < 0 then
        // Report the error.
        MessageBox ("Unable to retrieve key value from "+ FILE_NAME + ".", INFORMATION);
    else
        // Create a list to hold the paths that make up the search path
        // that was returned by GetProfString.
        listID = ListCreate (STRINGLIST);

        // Get each path from the search path into the list.
        if (StrGetTokens (listID, svSearchPath, ";") < 0) then
            // Report the error.
            MessageBox ("StrGetTokens failed.", SEVERE);
        else
            // Display the individual paths from the list.
            Sprintf (szMsg, "Paths found in %s %s", SECTION_NAME, KEY_NAME);
            SdShowInfoList ("Search Path", szMsg, listID);
        end if
    end if
end function

```

```

        endif;
    endif;

    // Remove the list from memory.
    ListDestroy (listID);

end;

```

## StrLength

The **StrLength** function returns the number of characters in a given string variable (that is, the number of code units in the UTF-16-encoded string) up to the first null character.

**StrLength** and **StrLengthChars** return the same results.

To obtain the number of characters in a string with embedded nulls, use **SizeOf**.

### Syntax

```
StrLength ( szString );
```

### Parameters

**Table 265** ▪ StrLength Parameters

| Parameter       | Description                                          |
|-----------------|------------------------------------------------------|
| <b>szString</b> | Specifies the string whose size is to be determined. |

### Return Values

**Table 266** ▪ StrLength Return Values

| Return Value  | Description                                                                                 |
|---------------|---------------------------------------------------------------------------------------------|
| <b>X</b>      | Where X is the number of characters in the string.                                          |
| <b>&lt; 0</b> | Indicates that the function was unable to determine the number of characters in the string. |

## StrLength Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*

```

```

* Demonstrates the StrLength function.
*
* StrLength is called to retrieve the number of characters in a
* string that an end user enters. The number of characters is
* displayed in a message box.
*
\*-----*/

#define TITLE_TEXT "StrLength Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_StrLength(HWND);

function ExFn_StrLength(hMSI)
    STRING svString, szTitle, szMsg;
    NUMBER nLength;
begin
    // Get a line of text from the end user.
    AskText ("Enter a line of text. ", "", svString);

    // Get the number of characters in the string.
    nLength = StrLength (svString);

    if (nLength < 0) then
        MessageBox ("StrLength failed.", SEVERE);
    else
        // Display the string length.
        szMsg = "String '%s' is %d characters long.";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svString, nLength);
    endif;

end;

```

## StrLengthChars

The **StrLengthChars** function returns the number of characters in a given string variable (that is, the number of code units in the UTF-16-encoded string) up to the first null character.

**StrLengthChars** and **StrLength** return the same results.

To obtain the number of characters in a string with embedded nulls, use **SizeOf**.

### Syntax

```
StrLengthChars ( szString );
```

## Parameters

**Table 267** ▪ StrLengthChars Parameters

| Parameter       | Description                                          |
|-----------------|------------------------------------------------------|
| <b>szString</b> | Specifies the string whose size is to be determined. |

## Return Values

**Table 268** ▪ StrLengthChars Return Values

| Return Value  | Description                                                                                 |
|---------------|---------------------------------------------------------------------------------------------|
| <b>X</b>      | Where X is the number of characters in the string.                                          |
| <b>&lt; 0</b> | Indicates that the function was unable to determine the number of characters in the string. |

## StrLengthChars Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the StrLengthChars function.
 *
 * StrLengthChars is called to retrieve the number of characters
 * in a string that an end user enters. The number of characters is
 * displayed in a message box.
 *
 \*-----*/

#define TITLE_TEXT "StrLengthChars Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_StrLengthChars(HWND);

function ExFn_StrLengthChars(hMSI)
    STRING svString, szTitle, szMsg;
    NUMBER nLength;
begin

    // Get a line of text from the end user.
    AskText ("Enter a line of text. ", "", svString);

    // Get the number of characters in the string.
    nLength = StrLengthChars (svString);

    if (nLength < 0) then

```

```

        MessageBox ("StrLengthChars failed.", SEVERE);
    else
        // Display the number of code units in the string.
        szMsg  = "String '%s' is %d code units long.";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svString, nLength);
    endif;

end;

```

## StrPutTokens

The **StrPutTokens** function extracts list items from the string list specified by listID and places them into the string specified by svString. The substrings placed into svString from listID are separated by szSeparator in the resulting string. Note that instances of szSeparator are *not* placed at the beginning and end of the string, only between list elements added to the string.

For example, if you call StrPutTokens with the list containing the items "One", "Two", "Three", "Four", and "Five" as the first parameter and ";" as the third parameter, svString will contain "One;Two;Three;Four;Five" after the function is called.

The value of bNull determines whether null characters are used to separate the substrings in the resulting string.

### Syntax

```
StrPutTokens( listID, svString, szSeparator, bNull );
```

## Parameters

**Table 269** ■ StrPutTokens Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>listID</b>      | Specifies the string list to be processed. The string list identified by listID must already have been initialized by a call to ListCreate. Note that this function does not work with number lists.                                                                                                                                                                |
| <b>svString</b>    | Specifies the resulting string.                                                                                                                                                                                                                                                                                                                                     |
| <b>szSeparator</b> | Specifies a string to be used to separate each list item in the resulting string. Note that unlike the StrGetTokens function, passing a null string in this parameter will <i>not</i> result in a null separated string; it will result in the substrings being placed one after the other with no separators. Set bNULL to TRUE to create a null separated string. |
| <b>bNull</b>       | If bNull is set to TRUE, null characters will be used to separate the substrings in the resulting string, and szSeparator will be ignored. Note that the resulting string will be double null terminated in this case. If bNull is set to FALSE, the substrings in the resulting string will be separated by szSeparator.                                           |

## Return Values

**Table 270** ■ StrPutTokens Return Values

| Return Value  | Description                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully created the string from the specified string list.           |
| <b>&lt; 0</b> | Indicates that the function was unable to create the specified string from the specified string list. |

# StrRemoveLastSlash

The **StrRemoveLastSlash** function removes the trailing backslash from a path specification. Because its purpose is to produce a valid path, StrRemoveLastSlash does not remove the backslash from a root directory specification, such as “A:\” or “C:\”.

## Syntax

```
StrRemoveLastSlash ( svPath );
```

## Parameters

**Table 271** ▪ StrRemoveLastSlash Parameters

| Parameter     | Description                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svPath</b> | Specifies a string whose value must be a path specification; returns the path without the trailing backslash. Note that if the path does not include a trailing backslash, it is returned unchanged. |

## Return Values

**Table 272** ▪ StrRemoveLastSlash Return Values

| Return Value  | Description                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully removed the trailing backslash or that the path does not contain a trailing backslash. |
| <b>&lt; 0</b> | Indicates that the function was unable to remove the trailing backslash.                                                        |

## Additional Information

StrRemoveLastSlash provides a convenient way to remove the trailing backslash from a path returned by AskPath or ParsePath. Because its purpose is to produce a valid path, StrRemoveLastSlash does not remove the backslash from a root directory specification, such as “A:\” or “C:\”; doing so would turn a valid path into a drive specification. If you need to remove the trailing backslash from a path in all cases, use the following script segment as a guide.

```
AskPath("", "", svPath);

if (StrLength(svPath) = 3)
    && (svPath[1] = ":")
    && (svPath[2] = "\\") then

    svTempString = svPath;
    StrSub(svPath,svTempString,0,2);
else
    StrRemoveLastSlash(svPath);
endif;
```

## StrRemoveLastSlash Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
```

```

* Demonstrates the StrRemoveLastSlash function.
*
* The AskPath dialog is displayed, prompting the user to
* specify a path. StrRemoveLastSlash is then called to remove
* the trailing backslash from the path returned by AskPath.
*
\*-----*/

#define TITLE_TEXT "StrRemoveLastSlash Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_StrRemoveLastSlash(HWND);

function ExFn_StrRemoveLastSlash(hMSI)
    STRING szDefaultPath, svString, szMsg, szTitle;
begin

    // Get a path from the user. AskPath returns the
    // path with a trailing backslash.
    AskPath ("Specify a path:", INSTALLDIR, svString);

    // Remove the last slash from the path.
    if (StrRemoveLastSlash (svString) < 0) then
        // Report an error.
        MessageBox ("StrRemoveLastSlash failed.", SEVERE);
    else
        // Display the folder name after the last backslash
        // has been removed.
        MessageBox ("Specified path: " + svString, INFORMATION);
    endif;

end;

```

## StrReplace

The **StrReplace** function searches svResult, beginning at the location specified by nStart, and replaces all found instances of szFind with szReplace.

### Syntax

```
StrReplace ( svResult, szFind, szReplace, nStart );
```

## Parameters

**Table 273** ▪ StrReplace Parameters

| Parameter        | Description                                                                                                                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svResult</b>  | Specifies the string to search. Returns the modified string.                                                                                                                                                                                                      |
| <b>szFind</b>    | Specifies the string to find in svResult.                                                                                                                                                                                                                         |
| <b>szReplace</b> | Specifies the string with which to replace found instances of szFind.                                                                                                                                                                                             |
| <b>nStart</b>    | Specifies an offset into svResult that identifies the character at which to begin the search for szFind. Note that the position of the first character in szString is 0 (zero). If you want to replace all instances of szFind in svResult, specify 0 for nStart. |

## Return Values

**Table 274** ▪ StrReplace Return Values

| Return Value              | Description                                                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>X</b>                  | The total number of replacements of szFind by szReplace.                                                                                                             |
| <b>&lt; ISERR_SUCCESS</b> | Indicates that the function failed. A value less than ISERR_SUCCESS is returned if szFind is a null string ("") or if nStart is greater than the length of svResult. |

# StrSub

The **StrSub** function copies part of the string specified by szString, beginning at the location specified by nStart. The parameter nLength specifies the number of characters to copy.

## Syntax

```
StrSub ( svSubStr, szString, nStart, nLength );
```

## Parameters

**Table 275** ▪ StrSub Parameters

| Parameter       | Description                                                                                                                                                                                                                                                                               |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svSubStr</b> | Returns the substring copied from szString.                                                                                                                                                                                                                                               |
| <b>szString</b> | Specifies the string from which the substring is to be copied.                                                                                                                                                                                                                            |
| <b>nStart</b>   | Specifies an offset into szString that identifies the first character to be copied. Note that the position of the first character in szString is 0 (zero). If the value passed in nStart is equal to or greater than the length of szString, a null string ("" ) is returned in svSubStr. |
| <b>nLength</b>  | Specifies the number of characters to copy from szString. If this value specifies more characters than exist between nStart and the end of szString, all characters from nStart to the end of the string are returned in svSubStr.                                                        |

## Return Values

**Table 276** ▪ StrSub Return Values

| Return Value | Description                                          |
|--------------|------------------------------------------------------|
| <b>X</b>     | Where X equals the number of characters in svSubStr. |

## StrSub Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the StrSub function.
*
* This script gets a date from the user and then calls StrSub
* to extract the four-digit year. Finally, the year is
* displayed in a message box.
*
\*-----*/

#define TITLE_TEXT "StrSub Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"
```

```

export prototype ExFn_StrSub(HWND);

function ExFn_StrSub(hMSI)
    STRING svYear, svDate, szQuestion, szTitle, szMsg;
    NUMBER nYear;
    BOOL bDateOk;
begin

    // Set up message parameter for call to AskText.
    szQuestion = "Please enter the date in this form MM/DD/YYYY:";

    repeat
        // Get a date from the user.
        AskText (szQuestion, "09/28/1998", svDate);

        // Check the format of the date entered by the user.
        bDateOk = (StrLength(svDate) = 10) &&
            (svDate[2] = "/" ) &&
            (svDate[5] = "/" );

        // If the date format is incorrect, report an error.
        if !bDateOk then
            MessageBox(svDate + " is not a date in the specified format.", WARNING);
        endif;
    until bDateOk ;

    // Retrieve the four-digit year, which starts at byte six.
    if (StrSub (svYear, svDate, 6, 4) < 0) then
        MessageBox ("StrSub failed.", SEVERE);
    endif;

    // Validate the year field.
    if StrToNum(nYear, svYear) = 0 then
        // Display the edited string.
        szMsg = "You specified the year %s";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg, svYear);
    else
        MessageBox(svDate + " is not a date in the specified format.", WARNING);
    endif;

end;

```

## STRTOCHAR

The **STRTOCHAR** function returns the first character of szString as data of type CHAR.

### Syntax

```
STRTOCHAR ( szString );
```

## Parameters

**Table 277** ▪ STRTOCHAR Parameters

| Parameter       | Description                                                                       |
|-----------------|-----------------------------------------------------------------------------------|
| <b>szString</b> | Specifies the string whose first character will be returned as data of type CHAR. |

## Return Values

**Table 278** ▪ STRTOCHAR Return Values

| Return Value | Description                                                     |
|--------------|-----------------------------------------------------------------|
| <b>char</b>  | The first character of szString expressed as data of type CHAR. |

## Additional Information

The STRTOCHAR function is useful when passing string literals to functions. Since InstallScript interprets double and single quotes as string delimiters, attempting to pass a literal character, for example, 'a', to a function that expects a character will cause a compiler error. To avoid this problem, pass the character literal to STRTOCHAR and pass the result of calling this function as the argument; for example:

```
Sprintf( szString, "%c", STRTOCHAR('a') );
```

# StrToLower

The **StrToLower** function converts all the letters in a string to lowercase. This function does not affect non-alphabetic characters.

## Syntax

```
StrToLower ( svTarget, szSource );
```

## Parameters

**Table 279** ▪ StrToLower Parameters

| Parameter       | Description                                                                |
|-----------------|----------------------------------------------------------------------------|
| <b>svTarget</b> | Returns the string in szSource with all characters converted to lowercase. |
| <b>szSource</b> | Specifies the string to convert to all lowercase characters.               |

## Return Values

**Table 280** ▪ StrToLower Return Values

| Return Value  | Description                                                              |
|---------------|--------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully changed the case of the string. |
| <b>&lt; 0</b> | Indicates that the function was unable to change the case of the string. |

## StrToLower Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the StrToUpper and StrToLower functions.
*
* StrToUpper is called to convert the characters in szSource
* from lowercase to uppercase.
*
* StrToLower is then called to convert the uppercase
* characters to lowercase.
*
\*-----*/

#define TITLE_TEXT "StrToUpper & StrToLower"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_StrToLower(HWND);
```

```

function ExFn_StrToLower(hMSI)
    STRING szSource, svTarget, szTitle, szMsg;
    NUMBER nReturn;
begin

    // Set up parameter for call to StrToUpper.
    szSource = "aBcDeF";

    // Convert all characters to upper case.
    nReturn = StrToUpper (svTarget, szSource);

    if (nReturn < 0) then
        MessageBox ("StrToUpper failed.", SEVERE);
    endif;

    szMsg = "Original: %s\n\nModified: %s";

    // Display the modified string.
    sprintfBox (INFORMATION, szTitle, szMsg, szSource, svTarget);

    // Set up parameter for call to StrToLower.
    szSource = "ABC123*&?d";

    // Convert all characters to lower case.
    nReturn = StrToLower (svTarget, szSource);

    if (nReturn < 0) then
        MessageBox ("StrToLower failed.", SEVERE);
    endif;

    // Display the modified string.
    szMsg = "Original: %s\n\nModified: %s\n(Note--Non-alphabetic chars " +
        "are not changed)";
    sprintfBox (INFORMATION, TITLE_TEXT, szMsg, szSource, svTarget);

end;

```

## StrToNum

The **StrToNum** function converts a string to a number, much like the C function `atol()`. It inspects `svString`, starting with the character at position 0 and continuing through the string until it reaches the end of the string or encounters a character that is not in the range "0"..."9". (The first character in the string can be a plus or minus sign.)

Then one of the following processes occurs:

- If all of the characters in the string are in the range "0".."9", the number represented by the string is assigned to `nvVar`.
- If the string begins with one or more characters in the range "0".."9" but also contains one or more non-numeric characters, a number based on the characters to the left of the first non-numeric character is assigned to `nvVar`. For example, if `szString` is "-123ABC456", `nvResult` will be -123.
- If the first character in the string is not in the range "0".."9" and is not a plus or minus sign, the function fails.

- If the first character in the string is a plus or minus sign and the second character is not in the range "0".."9", the function fails.

## Syntax

StrToNum ( nvVar, szString );

## Parameters

**Table 281** ▪ StrToNum Parameters

| Parameter       | Description                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvVar</b>    | Returns the number created from the string in szString.                                                                                                                                       |
| <b>szString</b> | Specifies the string to convert to a number. If the string corresponds to a number that is outside the range of allowed values for a number variable, this function gives unexpected results. |

## Return Values

**Table 282** ▪ StrToNum Return Values

| Return Value  | Description                                                                         |
|---------------|-------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully converted the string into a numeric value. |
| <b>&lt; 0</b> | Indicates that the function was unable to convert the string into a numeric value.  |

## StrToNum Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the StrToNum function.
*
* StrToNum is called to convert "1222240" to 1222240 and
* "1222ABC40" to 1222.
*
\*-----*/
```

```

#define TITLE_TEXT "StrToNum Example"
#define MSG_TEXT   "String: %s\n\nNumber: %d"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_StrToNum(HWND);

function ExFn_StrToNum(hMSI)
    STRING szString, szMsg;
    NUMBER nVar;
begin

    // Convert a string with numeric characters to a number.
    szString = "1222240";

    if (StrToNum (nVar, szString) < 0) then
        MessageBox ("StrToNum failed.", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE_TEXT, MSG_TEXT, szString, nVar);
    endif;

    // Convert string with non-numeric characters to a number.
    szString = "1222ABC40";

    if (StrToNum (nVar, szString) < 0) then
        MessageBox ("StrToNum failed.", SEVERE);
    else
        sprintfBox (INFORMATION, TITLE_TEXT, MSG_TEXT, szString, nVar);
    endif;

end;

```

## StrToNumHex

The **StrToNumHex** function converts a string to a number. It inspects `szString`, starting with the character at position 0 and continuing through the string until it reaches the end of the string or encounters a character that is not in the range "0"..."9", "a"..."f", "A"..."F". (The first two characters in the string may be "0x" or "0X".) Then one of the following processes occurs:

- If all of the characters in the string are in the range "0"..."9", the hexadecimal number represented by the string is assigned to `nvVar`.
- If the string begins with one or more characters in the hexadecimal range but also contains one or more non-hexadecimal characters, a number based on the characters to the left of the first non-hexadecimal character is assigned to `nvVar`. For example, if `szString` is "0x1A2GHI456", `nvResult` will be 418 (0x1A2).
- If the first character in the string is not in the hexadecimal range, the function fails.
- If the first two characters in the string are "0x" or "0X" and the third character is not in the hexadecimal range, the function fails.

## Syntax

```
StrToNumHex ( nvVar, szString );
```

## Parameters

**Table 283** ▪ StrToNumHex Parameters

| Parameter       | Description                                             |
|-----------------|---------------------------------------------------------|
| <b>nvVar</b>    | Returns the number created from the string in szString. |
| <b>szString</b> | Specifies the string to convert to a number.            |

## Return Values

**Table 284** ▪ StrToNumHex Return Values

| Return Value               | Description                                                                         |
|----------------------------|-------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully converted the string into a numeric value. |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to convert the string into a numeric value.  |

# StrToUpper

The **StrToUpper** function converts all the letters in a string to uppercase. This function does not affect non-alphabetic characters.

## Syntax

```
StrToUpper ( svTarget, szSource );
```

## Parameters

**Table 285** ▪ StrToUpper Parameters

| Parameter       | Description                                                                |
|-----------------|----------------------------------------------------------------------------|
| <b>svTarget</b> | Returns the string in szSource with all characters converted to uppercase. |
| <b>szSource</b> | Specifies the string to convert to all uppercase characters.               |

## Return Values

**Table 286** ▪ StrToUpper Return Values

| Return Value  | Description                                                              |
|---------------|--------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully changed the case of the string. |
| <b>&lt; 0</b> | Indicates that the function was unable to change the case of the string. |

## StrToUpper Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the StrToUpper and StrToLower functions.
*
* StrToUpper is called to convert the characters in szSource
* from lowercase to uppercase.
*
* StrToLower is then called to convert the uppercase
* characters to lowercase.
*
\*-----*/

#define TITLE_TEXT "StrToUpper & StrToLower"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_StrToUpper(HWND);
```

```

function ExFn_StrToUpper(hMSI)
    STRING szSource, svTarget, szTitle, szMsg;
    NUMBER nReturn;
begin

    // Set up parameter for call to StrToUpper.
    szSource = "aBcDeF";

    // Convert all characters to upper case.
    nReturn = StrToUpper (svTarget, szSource);

    if (nReturn < 0) then
        MessageBox ("StrToUpper failed.", SEVERE);
    endif;

    szMsg = "Original: %s\n\nModified: %s";

    // Display the modified string.
    sprintfBox (INFORMATION, szTitle, szMsg, szSource, svTarget);

    // Set up parameter for call to StrToLower.
    szSource = "ABC123*&?d";

    // Convert all characters to lower case.
    nReturn = StrToLower (svTarget, szSource);

    if (nReturn < 0) then
        MessageBox ("StrToLower failed.", SEVERE);
    endif;

    // Display the modified string.
    szMsg = "Original: %s\n\nModified: %s\n(Note--Non-alphabetic chars " +
        "are not changed)";
    sprintfBox (INFORMATION, TITLE_TEXT, szMsg, szSource, svTarget);

end;

```

## StrTrim

The **StrTrim** function removes the leading and trailing spaces and tabs from a string.

### Syntax

```
StrTrim (byref string svString);
```

## Parameters

**Table 287** ▪ StrTrim Parameters

| Parameter       | Description                       |
|-----------------|-----------------------------------|
| <b>svString</b> | Specify the string to be trimmed. |

## Return Values

**Table 288** ▪ StrTrim Return Values

| Return Value               | Description                                   |
|----------------------------|-----------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully trimmed the string. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to trim the string.       |

# SuiteFormatString

**Project** ▪ This information applies to the following project types:

- InstallScript
- Suite/Advanced UI

**Note** ▪ This function is available for InstallScript installations that may be included as InstallScript packages in an Advanced UI or Suite/Advanced UI installation. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

This function is also available for InstallScript actions that are included in Suite/Advanced UI installations. For more information, see [Working with an Action that Runs InstallScript Code in a Suite/Advanced UI Installation](#).

This function returns an error in the following scenarios:

- The function is called in an InstallScript installation that is launched directly (that is, not from an Advanced UI or Suite/Advanced UI installation).
- The function is called in an InstallScript installation that is included in an Advanced UI or Suite/Advanced UI installation as an executable package.

The **SuiteFormatString** function resolves formatted expressions that contain property names, environment variable references, and other special strings. At run time, the Advanced UI or Suite/Advanced UI installation expands the values of these expressions. The function stores the resulting string in a string variable.

## Syntax

```
SuiteFormatString (string szValue, string svFormattedValue);
```

## Parameters

**Table 289** ▪ SuiteFormatString Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szValue</b>          | Specify a string that includes one or more formatted expressions that contain property names, environment variable references, or other special strings. To learn about the syntax that is available for these expressions, see Using Formatted Expressions that Advanced UI and Suite/Advanced UI Installations Resolve at Run Time. |
| <b>svFormattedValue</b> | Specify the string variable that you want to contain the formatted string or expression. At run time, the installation expands the values of valid formatted expressions. Invalid expressions resolve to empty strings ("").                                                                                                          |

## Return Values

**Table 290** ▪ SuiteFormatString Return Values

| Return Value                      | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>              | The function successfully resolved the formatted expression.                                                                                                                                                                                                                                                                                                                                                           |
| <b>ISERR_ISERVICE_NOT_ENABLED</b> | The function was not called in an InstallScript package that was launched from an Advanced UI or Suite/Advanced UI installation, or from an InstallScript action in a Suite/Advanced UI installation. It was called in an InstallScript installation that was launched directly, or from an InstallScript installation that was included as an executable package in an Advanced UI or Suite/Advanced UI installation. |

## SuiteFormatString Example

```
//-----
//
//  InstallScript Example Script
//
//  Demonstrates the following functions:
//      *SuiteSetProperty
//      *SuiteGetProperty
//      *SuiteResolveString
//      *SuiteFormatString
//      *SuiteLogInfo
//
//  This sample can be called in an InstallScript package that is launched
//  from an Advanced UI or Suite/Advanced UI installation. This code logs
//  the following line in the Advanced UI or Suite/Advanced UI debug log:
//  SetGet: MyPropertyValue; Resolved: English (United States); Formatted: fmt MyPropertyValue;
//
//-----
```

```

function OnBegin()

STRING szValue;
STRING szResolved;
STRING szFormatted;

begin

    if SUITE_HOSTED then
        SuiteSetProperty ("MyPropertyName", "MyPropertyValue");
        SuiteGetProperty ("MyPropertyName", szValue);
        SuiteResolveString ("IDS_LANGUAGE_1033", szResolved);
        SuiteFormatString ("fmt [MyPropertyName]", szFormatted);
        SuiteLogInfo ("SetGet: %s; Resolved: %s; Formatted: %s;",
            szValue, szResolved, szFormatted);
    endif;

end;

```

## SuiteGetProperty

**Project** ▪ This information applies to the following project types:

- InstallScript
- Suite/Advanced UI

**Note** ▪ This function is available for InstallScript installations that may be included as InstallScript packages in an Advanced UI or Suite/Advanced UI installation. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

This function is also available for InstallScript actions that are included in Suite/Advanced UI installations. For more information, see [Working with an Action that Runs InstallScript Code in a Suite/Advanced UI Installation](#).

This function returns an error in the following scenarios:

- The function is called in an InstallScript installation that is launched directly (that is, not from an Advanced UI or Suite/Advanced UI installation).
- The function is called in an InstallScript installation that is included in an Advanced UI or Suite/Advanced UI installation as an executable package.

The **SuiteGetProperty** function retrieves the value of an Advanced UI or Suite/Advanced UI property from the Advanced UI or Suite/Advanced UI installation that is running the InstallScript package, or from the Suite/Advanced UI installation that is running the InstallScript action. The function stores the property value in a string variable.

### Syntax

```
SuiteGetProperty (string szName, string svValue);
```

## Parameters

**Table 291** ▪ SuiteGetProperty Parameters

| Parameter      | Description                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szName</b>  | Specify the name of the Advanced UI or Suite/Advanced UI property whose value you want to retrieve. It supports feature properties also like <code>FEATURE[name].actionState</code> . |
| <b>svValue</b> | Specify the string variable that you want to contain the value of the Advanced UI or Suite/Advanced UI property.                                                                      |

## Return Values

**Table 292** ▪ SuiteGetProperty Return Values

| Return Value                      | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>              | The function successfully retrieved the property value.                                                                                                                                                                                                                                                                                                                                                                |
| <b>ISERR_ISERVICE_NOT_ENABLED</b> | The function was not called in an InstallScript package that was launched from an Advanced UI or Suite/Advanced UI installation, or from an InstallScript action in a Suite/Advanced UI installation. It was called in an InstallScript installation that was launched directly, or from an InstallScript installation that was included as an executable package in an Advanced UI or Suite/Advanced UI installation. |

## SuiteGetProperty Example

```
//-----
//
//  InstallScript Example Script
//
//  Demonstrates the following functions:
//      *SuiteSetProperty
//      *SuiteGetProperty
//      *SuiteResolveString
//      *SuiteFormatString
//      *SuiteLogInfo
//
//  This sample can be called in an InstallScript package that is launched
//  from an Advanced UI or Suite/Advanced UI installation. This code logs
//  the following line in the Advanced UI or Suite/Advanced UI debug log:
//  SetGet: MyPropertyValue; Resolved: English (United States); Formatted: fmt MyPropertyValue;
//
//-----
```

```

function OnBegin()

STRING szValue;
STRING szResolved;
STRING szFormatted;

begin

    if SUITE_HOSTED then
        SuiteSetProperty ("MyPropertyName", "MyPropertyValue");
        SuiteGetProperty ("MyPropertyName", szValue);
        SuiteResolveString ("IDS_LANGUAGE_1033", szResolved);
        SuiteFormatString ("fmt [MyPropertyName]", szFormatted);
        SuiteLogInfo ("SetGet: %s; Resolved: %s; Formatted: %s;",
            szValue, szResolved, szFormatted);
    endif;

end;

```

## SuiteLogInfo

**Project** ▪ This information applies to the following project types:

- InstallScript
- Suite/Advanced UI

**Note** ▪ This function is available for InstallScript installations that may be included as InstallScript packages in an Advanced UI or Suite/Advanced UI installation. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

This function is also available for InstallScript actions that are included in Suite/Advanced UI installations. For more information, see [Working with an Action that Runs InstallScript Code in a Suite/Advanced UI Installation](#).

This function returns an error in the following scenarios:

- The function is called in an InstallScript installation that is launched directly (that is, not from an Advanced UI or Suite/Advanced UI installation).
- The function is called in an InstallScript installation that is included in an Advanced UI or Suite/Advanced UI installation as an executable package.

The **SuiteLogInfo** function logs information about the InstallScript package that is running in an Advanced UI or Suite/Advanced UI installation to the Advanced UI or Suite/Advanced UI debug log. It also logs information about the InstallScript action that is running in a Suite/Advanced UI installation to the Suite/Advanced UI debug log.

For information about generating an Advanced UI or Suite/Advanced UI debug log, see [Troubleshooting Issues with an Advanced UI or Suite/Advanced UI Installation](#).

### Syntax

```
SuiteLogInfo (string szFormat, arglist);
```

## Parameters

**Table 293** ▪ SuiteLogInfo Parameters

| Parameter       | Description                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFormat</b> | Specify a standard printf-style format string to be rendered and written to the Advanced UI or Suite/Advanced UI installation's debug log. |
| <b>arglist</b>  | Specify one or more arguments that correspond with the same number of format specifiers in szFormat.                                       |

## Return Values

**Table 294** ▪ SuiteLogInfo Return Values

| Return Value                      | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>              | The function successfully logged information.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ISERR_ISERVICE_NOT_ENABLED</b> | The function was not called in an InstallScript package that was launched from an Advanced UI or Suite/Advanced UI installation, or from an InstallScript action in a Suite/Advanced UI installation. It was called in an InstallScript installation that was launched directly, or from an InstallScript installation that was included as an executable package in an Advanced UI or Suite/Advanced UI installation. |

## SuiteLogInfo Example

```
//-----
//
//  InstallScript Example Script
//
//  Demonstrates the following functions:
//      *SuiteSetProperty
//      *SuiteGetProperty
//      *SuiteResolveString
//      *SuiteFormatString
//      *SuiteLogInfo
//
//  This sample can be called in an InstallScript package that is launched
//  from an Advanced UI or Suite/Advanced UI installation. This code logs
//  the following line in the Advanced UI or Suite/Advanced UI debug log:
//  SetGet: MyPropertyValue; Resolved: English (United States); Formatted: fmt MyPropertyValue;
//
//-----

function OnBegin()

STRING szValue;
STRING szResolved;
```

```

STRING szFormatted;

begin

    if SUITE_HOSTED then
        SuiteSetProperty ("MyPropertyName", "MyPropertyValue");
        SuiteGetProperty ("MyPropertyName", szValue);
        SuiteResolveString ("IDS_LANGUAGE_1033", szResolved);
        SuiteFormatString ("fmt [MyPropertyName]", szFormatted);
        SuiteLogInfo ("SetGet: %s; Resolved: %s; Formatted: %s;",
            szValue, szResolved, szFormatted);
    endif;

end;

```

## SuiteReportError

**Project** ▪ This information applies to the following project types:

- InstallScript
- Suite/Advanced UI

**Note** ▪ This function is available for InstallScript installations that may be included as InstallScript packages in an Advanced UI or Suite/Advanced UI installation. For more information, see [Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project](#).

This function returns an error in the following scenarios:

- The function is called in an InstallScript installation that is launched directly (that is, not from an Advanced UI or Suite/Advanced UI installation).
- The function is called in an InstallScript installation that is included in an Advanced UI or Suite/Advanced UI installation as an executable package.

The **SuiteReportError** function displays a message box in the Advanced UI or Suite/Advanced UI user interface to report an error that occurred as the Advanced UI or Suite/Advanced UI installation ran the InstallScript package.

### Syntax

```
SuiteReportError (string szMessage, nFlags);
```

## Parameters

**Table 295** ▪ SuiteReportError Parameters

| Parameter        | Description                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------|
| <b>szMessage</b> | Specify the error message that you want to display for end users.                                     |
| <b>nFlags</b>    | Specify any valid MessageBox flags. For valid flags, see <a href="#">MessageBox Function</a> on MSDN. |

## Return Values

**Table 296** ▪ SuiteReportError Return Values

| Return Value                      | Description                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_ISERVICE_NOT_ENABLED</b> | The function was not called in an InstallScript package that was launched from an Advanced UI or Suite/Advanced UI installation. It was called in an InstallScript installation that was launched directly, or from an InstallScript installation that was included as an executable package in an Advanced UI or Suite/Advanced UI installation. |
| <b>MessageBox Return Values</b>   | For possible return values, see <a href="#">MessageBox Function</a> on MSDN.                                                                                                                                                                                                                                                                      |

# SuiteResolveString

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *Suite/Advanced UI*

**Note** ▪ This function is available for InstallScript installations that may be included as InstallScript packages in an Advanced UI or Suite/Advanced UI installation. For more information, see *Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project*.

This function is also available for InstallScript actions that are included in Suite/Advanced UI installations. For more information, see *Working with an Action that Runs InstallScript Code in a Suite/Advanced UI Installation*.

This function returns an error in the following scenarios:

- The function is called in an InstallScript installation that is launched directly (that is, not from an Advanced UI or Suite/Advanced UI installation).
- The function is called in an InstallScript installation that is included in an Advanced UI or Suite/Advanced UI installation as an executable package.

The **SuiteResolveString** function replaces an Advanced UI or Suite/Advanced UI string identifier with its corresponding string value in the InstallScript package that is running in an Advanced UI or Suite/Advanced UI installation, or in the InstallScript action that is running in a Suite/Advanced UI installation.

## Syntax

```
SuiteResolveString (string szStringID, string svResolvedString);
```

## Parameters

**Table 297** ▪ SuiteResolveString Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szStringID</b>       | Specify the Advanced UI or Suite/Advanced UI string identifier that you want to be replaced.                                                                                                                                                                                    |
| <b>svResolvedString</b> | Specify the string variable that you want to store the value of the Advanced UI or Suite/Advanced UI string identifier; the value is based on the Advanced UI or Suite/Advanced UI installation's selected language. An unknown string identifier returns an empty string (""). |

## Return Values

**Table 298** ▪ SuiteResolveString Return Values

| Return Value                      | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>              | The function successfully replaced the string identifier with the corresponding string value.                                                                                                                                                                                                                                                                                                                          |
| <b>ISERR_ISERVICE_NOT_ENABLED</b> | The function was not called in an InstallScript package that was launched from an Advanced UI or Suite/Advanced UI installation, or from an InstallScript action in a Suite/Advanced UI installation. It was called in an InstallScript installation that was launched directly, or from an InstallScript installation that was included as an executable package in an Advanced UI or Suite/Advanced UI installation. |

## SuiteResolveString Example

```
//-----
//
// InstallScript Example Script
//
// Demonstrates the following functions:
//   *SuiteSetProperty
//   *SuiteGetProperty
//   *SuiteResolveString
//   *SuiteFormatString
//   *SuiteLogInfo
```

```
//
// This sample can be called in an InstallScript package that is launched
// from an Advanced UI or Suite/Advanced UI installation. This code logs
// the following line in the Advanced UI or Suite/Advanced UI debug log:
// SetGet: MyPropertyValue; Resolved: English (United States); Formatted: fmt MyPropertyValue;
//
//-----

function OnBegin()

STRING szValue;
STRING szResolved;
STRING szFormatted;

begin

    if SUITE_HOSTED then
        SuiteSetProperty ("MyPropertyName", "MyPropertyValue");
        SuiteGetProperty ("MyPropertyName", szValue);
        SuiteResolveString ("IDS_LANGUAGE_1033", szResolved);
        SuiteFormatString ("fmt [MyPropertyName]", szFormatted);
        SuiteLogInfo ("SetGet: %s; Resolved: %s; Formatted: %s;",
            szValue, szResolved, szFormatted);
    endif;

end;
```

## SuiteSetProperty

**Project** ▪ This information applies to the following project types:

- *InstallScript*
- *Suite/Advanced UI*

**Note** ▪ This function is available for *InstallScript* installations that may be included as *InstallScript* packages in an Advanced UI or Suite/Advanced UI installation. For more information, see *Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project*.

This function is also available for *InstallScript* actions that are included in Suite/Advanced UI installations. For more information, see *Working with an Action that Runs InstallScript Code in a Suite/Advanced UI Installation*.

This function returns an error in the following scenarios:

- The function is called in an *InstallScript* installation that is launched directly (that is, not from an Advanced UI or Suite/Advanced UI installation).
- The function is called in an *InstallScript* installation that is included in an Advanced UI or Suite/Advanced UI installation as an executable package.

The **SuiteSetProperty** function sets the value of an Advanced UI or Suite/Advanced UI property in the Advanced UI or Suite/Advanced UI installation that launched the running *InstallScript* package, or the value of a Suite/Advanced UI property in the Suite/Advanced UI installation that launched the running *InstallScript* action.

## Syntax

```
SuiteSetProperty (string szName, string szValue);
```

## Parameters

**Table 299** ▪ SuiteSetProperty Parameters

| Parameter      | Description                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szName</b>  | Specify the name of the Advanced UI or Suite/Advanced UI property whose value you want to set. It supports feature properties also like FEATURE[name].actionState. |
| <b>szValue</b> | Specify the value of the Advanced UI or Suite/Advanced UI property that you want to set.                                                                           |

## Return Values

**Table 300** ▪ SuiteSetProperty Return Values

| Return Value                      | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>              | The function successfully set the property value.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ISERR_ISERVICE_NOT_ENABLED</b> | The function was not called in an InstallScript package that was launched from an Advanced UI or Suite/Advanced UI installation, or from an InstallScript action in a Suite/Advanced UI installation. It was called in an InstallScript installation that was launched directly, or from an InstallScript installation that was included as an executable package in an Advanced UI or Suite/Advanced UI installation. |

## SuiteSetProperty Example

```
//-----
//
// InstallScript Example Script
//
// Demonstrates the following functions:
//   *SuiteSetProperty
//   *SuiteGetProperty
//   *SuiteResolveString
//   *SuiteFormatString
//   *SuiteLogInfo
//
// This sample can be called in an InstallScript package that is launched
// from an Advanced UI or Suite/Advanced UI installation. This code logs
// the following line in the Advanced UI or Suite/Advanced UI debug log:
// SetGet: MyPropertyValue; Resolved: English (United States); Formatted: fmt MyPropertyValue;
```

```
//
//-----

function OnBegin()

STRING szValue;
STRING szResolved;
STRING szFormatted;

begin

    if SUITE_HOSTED then
        SuiteSetProperty ("MyPropertyName", "MyPropertyValue");
        SuiteGetProperty ("MyPropertyName", szValue);
        SuiteResolveString ("IDS_LANGUAGE_1033", szResolved);
        SuiteFormatString ("fmt [MyPropertyName]", szFormatted);
        SuiteLogInfo ("SetGet: %s; Resolved: %s; Formatted: %s;",
            szValue, szResolved, szFormatted);
    endif;

end;
```

## System

The **System** function is documented for backward compatibility with InstallShield Professional. With newer versions of InstallShield, RebootDialog and SdFinishReboot are better functions to use to restart Windows or reboot the system. Of these two, SdFinishReboot provides the most functionality. Refer to the individual function descriptions to see which one best meets your needs.

Use the System function to restart Windows or reboot the system after an installation has completed. System does not perform an aborted setup—that is, it does not remove installed files. However, InstallShield does remove any temporary directories and temporary files it placed on the system to carry out the setup. To reboot the system immediately after calling the System function, use the exit keyword immediately after calling the System function.

Some systems may not restart or may hang when this function is called. Many setup routines (including installation for system software such as MS-DOS) display a warning message to the user before they restart the system. This warning message indicates what is happening and instructs the user to reboot the system manually if the command fails.

**Note** - This function calls the Windows API *ExitWindows*. Due to the wide variety of BIOS types, this function is highly dependent on the BIOS interaction with the system.

### Syntax

```
System ( nOp );
```

## Parameters

**Table 301** ▪ System Parameters

| Parameter | Description                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nOp       | Specifies which action to perform after terminating the setup. Pass the following predefined constant in this parameter: <ul style="list-style-type: none"> <li><b>SYS_BOOTMACHINE</b>—Reboots the system.</li> </ul> |

## System Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the System function.
 *
 * This script reboots the computer.
 *
 \*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_System(HWND);

function ExFn_System(hMSI)
begin

    System (SYS_BOOTMACHINE);

end;
```

## TextSubGetValue

The **TextSubGetValue** function retrieves in svValue the text substitution string that is associated with szTextSub. The bGlobalOnly parameter specifies whether the function searches for local text substitutions.

### Syntax

```
TextSubGetValue ( szTextSub, svValue, bGlobalOnly, bResolveEmbedded );
```

## Parameters

**Table 302** ▪ TextSubGetValue Parameters

| Parameter               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTextSub</b>        | Specifies the string that is replaced by svValue when text substitution is performed. You can optionally enclose the string value in angle brackets, for example, "<MYTEXTSUB>". If you enclose the string value in angle brackets, you can include additional text in the string outside the angle brackets (for example, "additional<MYTEXTSUB>text") that is automatically removed before text substitution is performed.                                                                                                                                                           |
| <b>svValue</b>          | Returns the string that replaces occurrences of szTextSub when text substitution is performed. This string value can itself contain embedded text substitutions. For more information, see <a href="#">Text Substitutions</a> .                                                                                                                                                                                                                                                                                                                                                        |
| <b>bGlobalOnly</b>      | Specifies whether TextSubGetValue searches among only global text substitutions (TRUE) or both global and local text substitutions (FALSE). For more information, see <a href="#">Text Substitutions</a> .                                                                                                                                                                                                                                                                                                                                                                             |
| <b>bResolveEmbedded</b> | Specifies whether to perform any embedded text substitutions. For more information, see <a href="#">Text Substitutions</a> . See the following example code and comment lines: <pre>TextSubSetValue ( "&lt;MYTEXTSUB1&gt;", "First Text Sub", FALSE ); TextSubSetValue ( "&lt;MYTEXTSUB2&gt;", "Second Text Sub &lt;MYTEXTSUB1&gt;", FALSE ); TextSubGetValue ( "&lt;MYTEXTSUB2&gt;", svValue, FALSE, TRUE ); // svValue is "Second Text Sub First Text Sub" TextSubGetValue ( "&lt;MYTEXTSUB2&gt;", svValue, FALSE, FALSE ); // svValue is "Second Text Sub &lt;MYTEXTSUB1&gt;"</pre> |

## Return Values

**Table 303** ▪ TextSubGetValue Return Values

| Return Value              | Description                                                   |
|---------------------------|---------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | TextSubGetValue successfully retrieved the associated string. |
| <b>&lt; ISERR_SUCCESS</b> | TextSubGetValue failed to retrieve the associated string.     |

## TextSubGetValue Example

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the TextSub* functions: TextSubSetValue,
* TextSubSubstitute, TextSubGetValue, and TextSubParseTextSub.
*
\*-----*/

function OnBegin( )
    string svString, svValue;
begin
    TextSubSetValue ( "<MYTEXTSUB1>", "First Text Sub", FALSE );
    svString = "Text <MYTEXTSUB1> String";
    TextSubSubstitute ( svString, FALSE );
    MessageBox( svString, INFORMATION );
    // svString is "Text First Text Sub String"

    TextSubSetValue ( "<MYTEXTSUB2>", "Second Text Sub <MYTEXTSUB1>", FALSE );
    TextSubGetValue ( "<MYTEXTSUB2>", svValue, FALSE, TRUE );
    MessageBox( svValue, INFORMATION );
    // svValue is "Second Text Sub First Text Sub"
    TextSubGetValue ( "<MYTEXTSUB2>", svValue, FALSE, FALSE );
    MessageBox( svValue, INFORMATION );
    // svValue is "Second Text Sub <MYTEXTSUB1>"

    svString = "Text <MYTEXTSUB1> String";
    TextSubParseTextSub ( svString );
    MessageBox( svString, INFORMATION );
    // svString is "MYTEXTSUB1"
end;

```

## TextSubParseTextSub

The **TextSubParseTextSub** function searches svTextSub for a substring that is enclosed in angle brackets (which is a standard way of denoting a text substitution string). If TextSubParseTextSub finds such a substring, it returns the first such substring, without the enclosing angle brackets, in svTextSub; otherwise, TextSubParseTextSub does not change svTextSub.

### Syntax

```
TextSubParseTextSub ( svTextSub );
```

## Parameters

**Table 304** ▪ TextSubParseTextSub Parameters

| Parameter        | Description                                  |
|------------------|----------------------------------------------|
| <b>svTextSub</b> | Specifies the string that is to be searched. |

## Return Values

**Table 305** ▪ TextSubParseTextSub Return Values

| Return Value         | Description                                 |
|----------------------|---------------------------------------------|
| <b>ISERR_SUCCESS</b> | This function always returns ISERR_SUCCESS. |

## TextSubParseTextSub Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the TextSub* functions: TextSubSetValue,
 * TextSubSubstitute, TextSubGetValue, and TextSubParseTextSub.
 *
 \*-----*/

function OnBegin( )
    string svString, svValue;
begin
    TextSubSetValue ( "<MYTEXTSUB1>", "First Text Sub", FALSE );
    svString = "Text <MYTEXTSUB1> String";
    TextSubSubstitute ( svString, FALSE );
    MessageBox( svString, INFORMATION );
    // svString is "Text First Text Sub String"

    TextSubSetValue ( "<MYTEXTSUB2>", "Second Text Sub <MYTEXTSUB1>", FALSE );
    TextSubGetValue ( "<MYTEXTSUB2>", svValue, FALSE, TRUE );
    MessageBox( svValue, INFORMATION );
    // svValue is "Second Text Sub First Text Sub"
    TextSubGetValue ( "<MYTEXTSUB2>", svValue, FALSE, FALSE );
    MessageBox( svValue, INFORMATION );
    // svValue is "Second Text Sub <MYTEXTSUB1>"

    svString = "Text <MYTEXTSUB1> String";
    TextSubParseTextSub ( svString );
    MessageBox( svString, INFORMATION );
    // svString is "MYTEXTSUB1"
end;

```

# TextSubSetValue

The **TextSubSetValue** function creates a text substitution association between szTextSub and szValue. The bGlobal parameter specifies whether the association is global or local.

## Syntax

```
TextSubSetValue ( szTextSub, szValue, bGlobal );
```

## Parameters

**Table 306** ▪ TextSubSetValue Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szTextSub</b> | <p>Specifies the string that is replaced by szValue when text substitution is performed. You can optionally enclose the string value in angle brackets, for example, "&lt;MYTEXTSUB&gt;". If you enclose the string value in angle brackets, you can include additional text in the string outside the angle brackets (for example, "additional&lt;MYTEXTSUB&gt;text") that is automatically removed before text substitution is performed.</p> <div>  <p><b>Note</b> ▪ In order to avoid conflicts with existing text substitutions that are created internally or by objects used by the installation, it is recommended that any values of szTextSub that you specify in TextSubSetValue use a prefix that is specific to the installation.</p> </div> |
| <b>szValue</b>   | <p>Specifies the string that replaces occurrences of szTextSub when text substitution is performed. This string value can itself contain embedded text substitutions. For more information, see <a href="#">Text Substitutions</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>bGlobal</b>   | <p>Specifies whether the association between szTextSub and szValue is global or local; for more information, see <a href="#">Text Substitutions</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Return Values

**Table 307** ▪ TextSubSetValue Return Values

| Return Value              | Description                                                    |
|---------------------------|----------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | TextSubSetValue successfully associated the specified strings. |
| <b>&lt; ISERR_SUCCESS</b> | TextSubSetValue failed to associate the specified strings.     |

## TextSubSetValue Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the TextSub* functions: TextSubSetValue,
 * TextSubSubstitute, TextSubGetValue, and TextSubParseTextSub.

```

```

*
\*-----*/

function OnBegin( )
    string svString, svValue;
begin
    TextSubSetValue ( "<MYTEXTSUB1>", "First Text Sub", FALSE );
    svString = "Text <MYTEXTSUB1> String";
    TextSubSubstitute ( svString, FALSE );
    MessageBox( svString, INFORMATION );
    // svString is "Text First Text Sub String"

    TextSubSetValue ( "<MYTEXTSUB2>", "Second Text Sub <MYTEXTSUB1>", FALSE );
    TextSubGetValue ( "<MYTEXTSUB2>", svValue, FALSE, TRUE );
    MessageBox( svValue, INFORMATION );
    // svValue is "Second Text Sub First Text Sub"
    TextSubGetValue ( "<MYTEXTSUB2>", svValue, FALSE, FALSE );
    MessageBox( svValue, INFORMATION );
    // svValue is "Second Text Sub <MYTEXTSUB1>"

    svString = "Text <MYTEXTSUB1> String";
    TextSubParseTextSub ( svString );
    MessageBox( svString, INFORMATION );
    // svString is "MYTEXTSUB1"
end;

```

## TextSubSubstitute

The **TextSubSubstitute** function performs text substitution on svString. The bGlobalOnly parameter specifies whether the function performs local text substitutions.

### Syntax

```
TextSubSubstitute ( svString, bGlobalOnly );
```

## Parameters

**Table 308** ▪ TextSubSubstitute Parameters

| Parameter          | Description                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svString</b>    | Specifies the string on which text substitution is performed.                                                                                                                                          |
| <b>bGlobalOnly</b> | Specifies whether TextSubSubstitute performs only global text substitutions (TRUE) or both global and local text substitutions (FALSE); for more information, see <a href="#">Text Substitutions</a> . |

## Return Values

**Table 309** ▪ TextSubSubstitute Return Values

| Return Value              | Description                                                 |
|---------------------------|-------------------------------------------------------------|
| <b>ISERR_SUCCESS</b>      | TextSubSubstitute successfully performed text substitution. |
| <b>&lt; ISERR_SUCCESS</b> | TextSubSubstitute failed to perform text substitution.      |

## TextSubSubstitute Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the TextSub* functions: TextSubSetValue,
 * TextSubSubstitute, TextSubGetValue, and TextSubParseTextSub.
 *
 \*-----*/

function OnBegin( )
    string svString, svValue;
begin
    TextSubSetValue ( "<MYTEXTSUB1>", "First Text Sub", FALSE );
    svString = "Text <MYTEXTSUB1> String";
    TextSubSubstitute ( svString, FALSE );
    MessageBox( svString, INFORMATION );
    // svString is "Text First Text Sub String"

    TextSubSetValue ( "<MYTEXTSUB2>", "Second Text Sub <MYTEXTSUB1>", FALSE );
    TextSubGetValue ( "<MYTEXTSUB2>", svValue, FALSE, TRUE );
    MessageBox( svValue, INFORMATION );
    // svValue is "Second Text Sub First Text Sub"
    TextSubGetValue ( "<MYTEXTSUB2>", svValue, FALSE, FALSE );
    MessageBox( svValue, INFORMATION );

```

```
// svValue is "Second Text Sub <MYTEXTSUB1>"

svString = "Text <MYTEXTSUB1> String";
TextSubParseTextSub ( svString );
MessageBox( svString, INFORMATION );
// svString is "MYTEXTSUB1"
end;
```

# Built-In Functions (U-Z)

For a list of functions by category, see [Built-In Functions by Category](#).

## UninstallApplication

---

**Project** ▪ *This information applies to InstallScript projects.*

The **UninstallApplication** function launches the uninstallation that is specified by szUninstallKey.

### Syntax

```
UninstallApplication ( szUninstallKey, szAdditionalCmdLine, nOptions );
```

## Parameters

**Table 1** • UninstallApplication Parameters

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szUninstallKey</b>      | Specifies the name of a subkey under the target registry's <root key>\Software\Microsoft\Windows\CurrentVersion\Uninstall key; the function first checks for the subkey under the root key HKEY_CURRENT_USER, and if it does not find the subkey there, it checks under HKEY_LOCAL_MACHINE. For setups created with InstallShield Professional 5.53 or earlier, this is typically the name of the application; for setups created with InstallShield Professional 6.0 or later, this is the application's product GUID including the surrounding braces ({}). Do not enter the product GUID of the current setup. |
| <b>szAdditionalCmdLine</b> | Specifies any additional command line arguments that you want to pass to the uninstallation. You do not need to specify command line arguments that are already specified in szUninstallKey's UninstallString value's data.                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>nOptions</b>            | Specifies additional options. You can specify any option that is supported by <a href="#">LaunchApplication</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Return Values

**Table 2** • UninstallApplication Return Values

| Return Value               | Description                                                                                                                                                                                                                                      |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function successfully launched the uninstallation.                                                                                                                                                                            |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function was unable to launch the uninstallation.<br><br>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <a href="#">FormatMessage</a> . |

# UnUseDLL

The **UnUseDLL** function unloads a .dll file from memory. **UnUseDLL** decrements the lock count of the .dll file by one. When the lock count equals zero, the InstallScript engine unloads the .dll file. Every call to **UseDLL** should have a matching call to **UnUseDLL** so that .dll files are not left in memory after they are no longer needed, using system resources. After you unload a .dll file, you cannot call the functions in that .dll file.

If the script exits or terminates before properly unloading the .dll file with **UnUseDLL**, the .dll file is locked in memory. If you attempt to access the .dll file again, your script might fail. You must remove the .dll file from memory by restarting Windows.

**Caution** ▪ Microsoft Windows system .dll files, such as User32.dll, Gdi32.dll, and Kernel32.dll, are loaded and unloaded automatically by Windows. Do not call **UseDLL** and **UnUseDLL** to load and unload these .dll files.

## Syntax

```
UnUseDLL ( szDLLName );
```

## Parameters

**Table 3** ▪ UnUseDLL Parameters

| Parameter        | Description                                                                          |
|------------------|--------------------------------------------------------------------------------------|
| <b>szDLLName</b> | Specifies the file name of the .dll file. Do not include the path in this parameter. |

## Return Values

**Table 4** ▪ UnUseDLL Return Values

| Return Value  | Description                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully unlocked and possibly unloaded the .dll file from memory. |
| <b>&lt; 0</b> | Indicates that the function was unable to unlock or unload the .dll file.                          |

## UnUseDLL Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
```

```

*
* Demonstrates the UseDLL and the UnUseDLL functions.
*
* UseDLL is called to load an example .dll file into memory. A
* function in this .dll file is then called to demonstrate how
* .dll functions can be used in an installation. Finally,
* UnUseDLL is called to unload the example .dll file from memory.
*
* Note: This script requires that the constant DLL_FILE be set
*       to the fully qualified name of a .dll file that contains
*       a function called TheExportedFunction. The format of that
*       function must match the prototype declaration below.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

#define DLL_FILE SUPPORTDIR ^ "TheDLL.dll"

// Prototype TheExportedFunction in TheDLL.dll.
prototype TheDLL.TheExportedFunction (INT, WPOINTER);

export prototype ExFn_UnUseDLL(HWND);

function ExFn_UnUseDLL(hMSI)
    STRING    svString;
    INT       nValue;
    WPOINTER  psvString;
    NUMBER    nResult;
    BOOL      bDone;
begin

    // Load the .dll file into memory.
    nResult = UseDLL (DLL_FILE);

    if (nResult = 0) then
        MessageBox ("UseDLL successful \n\n.dll file loaded.", INFORMATION);
    else
        MessageBox ("UseDLL failed.\n\nCouldn't load .dll file.", INFORMATION);
        abort;
    endif;

    // bDone controls the following while loop.
    bDone = FALSE;

    // Loop while bDone is FALSE.
    while (bDone = FALSE)
        // Disable the Back button in installation dialogs.
        Disable (BACKBUTTON);

        // Get a string from the user.
        AskText ("Enter an example string.", "Example string.", svString);

        // Get a pointer to the string to pass to TheExportedFunction.
        psvString = &svString;

```

```

// Get the string length to pass to TheExportedFunction.
nValue = StrLength (svString);

// Call TheExportedFunction.
TheExportedFunction (nValue, psvString);

// Display the string to observe how it was altered by TheExportedFunction.
SprintfBox (INFORMATION, "UseDLL", "TheExportedFunction() changed the string " +
            "to: %s", svString);

// Give the user a chance to do another example.
if (AskYesNo ("Do another example?", YES) = NO) then
    bDone = TRUE;
endif;
endwhile;

// Remove the .dll file from memory.
if (UnUseDLL (DLL_FILE) < 0) then
    MessageBox ("UnUseDLL failed.\n\n.dll file still in memory.", SEVERE);
else
    MessageBox ("UnUseDLL successful.\n\n.dll file removed from memory.",
                INFORMATION);
endif;

end;

```

## UpdateServiceCheckForUpdates

**Project** • This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPLEMENTED.

For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

### Syntax

```
UpdateServiceCheckForUpdates ( szProductCode, bWait );
```

## UpdateServiceCreateShortcut

**Project** • This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPLEMENTED.

### Syntax

```
UpdateServiceCreateShortcut ( szProductCode, szFolder, szItemName );
```

# UpdateServiceEnableUpdateManagerInstall

**Project** ▪ This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPLEMENTED.

For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## Syntax

```
UpdateServiceEnableUpdateManagerInstall (BOOL bEnable);
```

# UpdateServiceGetAgentTarget

**Project** ▪ This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns a null string ("").

For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## Syntax

```
UpdateServiceGetAgentTarget ( );
```

# UpdateServiceOnEnabledStateChange

**Project** ▪ This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPLEMENTED.

For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## Syntax

```
UpdateServiceOnEnabledStateChange ( );
```

# UpdateServiceRegisterProduct

**Project** ▪ This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPLEMENTED.

For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## Syntax

```
UpdateServiceRegisterProduct ( szProductCode, szProductVersion, bRegister, nInterval );
```

# UpdateServiceRegisterProductEx

**Project** ▪ This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPLEMENTED.

For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## Syntax

```
UpdateServiceRegisterProductEx (BOOL bRegister);
```

# UpdateServiceSetHost

**Project** ▪ This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPLEMENTED.

For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## Syntax

```
UpdateServiceSetHost ( szProductCode, szHostURL );
```

# UpdateServiceSetLanguage

**Project** ▪ This information applies to InstallScript projects.

This function is obsolete. If this function is called, it returns ISERR\_NOT\_IMPLEMENTED.

For information on adding FlexNet Connect support to an InstallScript project, consult the [Knowledge Base](#).

## Syntax

```
UpdateServiceSetLanguage ( szProductCode, nLanguageID );
```

# UseDLL

---

**Important** ▪ For important information regarding the use of **UseDLL** function and the current directory, see [Current Directory Removed from DLL Search Path to Safeguard Against DLL Preloading Attacks](#).

The **UseDLL** function loads a .dll file into memory. After the .dll file has been loaded into memory, your installation script can call a function from that .dll file. Note that if the .dll file that is specified by szDLLName requires other .dll files, those other .dll files must reside in the folder from which the .dll file attempts to load them. Normally this will be the current folder. To ensure that those .dll files can be located, call **ChangeDirectory** to change the current folder to the location of those .dll files before calling **UseDLL**. Failure to do so may prevent the .dll file from loading properly.

Each time that you load a .dll file into memory, the .dll file's lock count is incremented. The lock count identifies the number of applications that are using the .dll file. You should call **UnUseDLL** to unload a .dll file as soon as you are done using it. If you do not unload a .dll file when you are done with it, the .dll file will remain in memory when no applications need it, thereby wasting system resources. Every call to **UseDLL** should have a matching call to **UnUseDLL** in the script.

---

**Caution** ▪ Microsoft Windows system .dll files, such as User32.dll, Gdi32.dll, and Kerne132.dll, are loaded and unloaded automatically by Windows. Do not call **UseDLL** and **UnUseDLL** to load and unload these .dll files.

## Syntax

```
UseDLL ( szDLLName );
```

## Parameters

**Table 5** • UseDLL Parameters

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szDLLName</b> | <p>Specifies the name of the .dll file to be loaded. If you do not specify an extension, the InstallScript engine assumes that the file has the extension .dll or .exe. Including a path in this parameter is recommended but optional. If the path for the .dll file is not specified in this parameter, the InstallScript engine searches for the .dll file using the same search order that the Windows API function <b>LoadLibrary</b> uses. For more information regarding the search order, see the description of this Windows API function on MSDN.</p> <p>To include the .dll file in your installation, add it to the appropriate subfolder of the Language Independent folder in the Support Files view. When the installation is running on a target system, the .dll file is available in the temporary directory that is specified by SUPPORTDIR. You can then append the .dll file name to SUPPORTDIR as follows in order to reference the .dll file:</p> <pre>szDLLName = SUPPORTDIR ^ "TheDLL.dll";    UseDLL (szDLLName);</pre> <p>If you do not place your .dll file into your installation (by inserting it into the appropriate folder in the Support Files view), you can instead distribute the file along with the files of your application and then load it from the target system. However, if you do so, you must specify the location to which you install the .dll file so that your installation can reference it. You must also ensure that your installation does not attempt to load the .dll file before it has been transferred to the target system.</p> <div>  <p><b>Note</b> • The <i>szDLLName</i> parameter does not support uniform resource locators (URLs).</p> </div> |

## Return Values

**Table 6** • UseDLL Return Values

| Return Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully loaded the .dll file into memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>&lt; 0</b> | <p>Indicates that the function was unable to load the .dll file into memory.</p> <p>If <b>UseDLL</b> fails, the most likely cause is that the .dll file was not found. If this happens, make sure that the correct path is specified in the parameter <i>szDLLName</i>.</p> <p>Another common cause of failure that is associated with using .dll files is related to .dll file dependencies—.dll files that are accessed by the .dll file that you load. If the .dll files that your .dll file must access are not loaded or found, your .dll file call may fail. If this occurs, make sure that the other .dll files are on the system and that they are accessible.</p> <p>If the script exits or terminates before properly unloading the .dll file with <b>UnUseDLL</b>, the .dll file will be locked in memory. If you attempt to access the .dll file again, your script may fail. You must remove the .dll file from memory by restarting Windows.</p> |

## Current Directory Removed from DLL Search Path to Safeguard Against DLL Preloading Attacks

Starting in InstallShield 2018, to safeguard installations against DLL preloading attacks, InstallShield has removed the current directory from the standard DLL search path by calling the SetDllDirectory Windows API with an empty string ("").

If a DLL links implicitly to the other DLLs, or loads them dynamically using LoadLibrary() without specifying a fully qualified path name, the UseDLL() InstallScript function cannot load the dependencies from the current working directory.

You can work around this issue by prototyping SetDllDirectoryW (prototype number kernel32.SetDllDirectoryW(wstring); ) and call it with SUPPORTDIR to get the support folder to be in the DLL load search path.

In InstallShield 2018, the following changes have been made:

- The DLL\_DIRECTORY\_SUPPORTDIR constant was added to the **Enable** function so that customers can explicitly opt-in to using SUPPORTDIR as a DLL directory.
- The DLL\_DIRECTORY\_SUPPORTDIR constant was added to the **Disable** function so that customers can explicitly opt-out to using SUPPORTDIR as a DLL directory.
- The SetDllDirectory (szPathName) wrapper function was added so that customers can explicitly opt-in to using any directory as a DLL directory. If the parameter is an empty string (""), the call removes the current directory from the default DLL search order.

## UseDLL Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the UseDLL and the UnUseDLL functions.
*
* UseDLL is called to load an example .dll file into memory. A
* function in this .dll file is then called to demonstrate how
* .dll functions can be used in an installation. Finally,
* UnUseDLL is called to unload the example .dll file from memory.
*
* Note: This script requires that the constant DLL_FILE be set
*       to the fully qualified name of a .dll file that contains
*       a function called TheExportedFunction. The format of that
*       function must match the prototype declaration below.
*
\*-----*/

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"
```

```

#define DLL_FILE SUPPORTDIR ^ "TheDLL.dll"

// Prototype TheExportedFunction in TheDLL.dll.
prototype TheDLL.TheExportedFunction (INT, WPOINTER);

export prototype ExFn_UseDLL(HWND);

function ExFn_UseDLL(hMSI)
    STRING    svString;
    INT       nValue;
    WPOINTER  psvString;
    NUMBER    nResult;
    BOOL      bDone;
begin

    // Load the .dll file into memory.
    nResult = UseDLL (DLL_FILE);

    if (nResult = 0) then
        MessageBox ("UseDLL successful \n\n.dll file loaded.", INFORMATION);
    else
        MessageBox ("UseDLL failed.\n\nCouldn't load .dll file.", INFORMATION);
        abort;
    endif;

    // bDone controls the following while loop.
    bDone = FALSE;

    // Loop while bDone is FALSE.
    while (bDone = FALSE)
        // Disable the Back button in installation dialogs.
        Disable (BACKBUTTON);

        // Get a string from the user.
        AskText ("Enter an example string.", "Example string.", svString);

        // Get a pointer to the string to pass to TheExportedFunction.
        psvString = &svString;

        // Get the string length to pass to TheExportedFunction.
        nValue = StrLength (svString);

        // Call TheExportedFunction.
        TheExportedFunction (nValue, psvString);

        // Display the string to observe how it was altered by TheExportedFunction.
        SprintfBox (INFORMATION, "UseDLL", "TheExportedFunction() changed the string " +
            "to: %s", svString);

        // Give the user a chance to do another example.
        if (AskYesNo ("Do another example?", YES) = NO) then
            bDone = TRUE;
        endif;
    endwhile;

    // Remove the .dll file from memory.

```

```
if (UnUseDLL (DLL_FILE) < 0) then
    MsgBox ("UnUseDLL failed.\n\n.dll file still in memory.", SEVERE);
else
    MsgBox ("UnUseDLL successful.\n\n.dll file removed from memory.",
        INFORMATION);
endif;

end;
```

## VarInit

The **VarInit** function initializes or reinitializes internal lists used by the **VarSave** and **VarRestore** functions. Calling this function effectively clears any information stored by previous **VarSave** calls and not yet used by subsequent **VarRestore** functions.

### Syntax

```
VarInit (nType);
```

## Parameters

**Table 7 • VarInit Parameters**

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nType</b> | <p>Specifies which information to reset. Pass one of the following predefined constants in this parameter.</p> <div>  </div> <hr/> <p><b>Project •</b> <i>These constants apply to InstallScript projects:</i></p> <ul style="list-style-type: none"> <li>• <b>VAR_LOGGING</b>—Resets any stored uninstall logging entries.</li> <li>• <b>VAR_CURRENTDIR</b>—Resets any stored current directory entries.</li> <li>• <b>VAR_ALLSUPPORTED</b>—Resets all stored entries.</li> <li>• <b>VAR_HKEYCURRENTROOTKEY</b>—Resets any stored current root key entries.</li> <li>• <b>CURRENTROOTKEY</b>—This constant is obsolete. ## Return Values

**Table 8 • VarInit Return Values**

| Return Value         | Description                                                           |
|----------------------|-----------------------------------------------------------------------|
| <b>ISERR_SUCCESS</b> | Indicates that the current values of the system variables were reset. |

## VarRestore

The **VarRestore** function reassigns the values that were saved by an earlier call to the **VarSave** function to the system variables TARGETDIR (in InstallScript installations), INSTALLDIR (in Basic MSI and InstallScript MSI installations), SRCDIR, or HKEYCURRENTROOTKEY. Call **VarSave** whenever you need to change the value of these system variables temporarily, for example, to set source and target directories before a call to **XCOPYFile**.

Afterwards, set those variables back to their previous values by calling **VarRestore**.

### Syntax

```
VarRestore ( nType );
```

## Parameters

**Table 9** • VarRestore Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nType</b> | <p>Specifies which system variables to restore. Pass one or more of the following predefined constants in this parameter. Note that you can pass multiple constants separated by the OR operator (  ).</p> <div>  </div> <p><b>Project</b> ▪ These constants apply to InstallScript projects:</p> <ul style="list-style-type: none"> <li>• <b>VAR_LOGGING</b>—Resets any stored uninstallation logging entries.</li> <li>• <b>VAR_CURRENTDIR</b>—Resets any stored current directory entries.</li> <li>• <b>VAR_ALLSUPPORTED</b>—Resets all stored entries.</li> <li>• <b>VAR_HKEYCURRENTROOTKEY</b>—Resets any stored current root key entries.</li> <li>• <b>VAR_REGOPTIONS</b>—Resets any stored current registry options.</li> <li>• <b>CURRENTROOTKEY</b>—This constant is obsolete. Use VAR_HKEYCURRENTROOTKEY instead.</li> </ul> <div>  </div> <p><b>Project</b> ▪ This constant applies to Basic MSI, InstallScript, and InstallScript MSI projects:</p> <ul style="list-style-type: none"> <li>• <b>VAR_SRCTARGETDIR or SRCTARGETDIR</b>—Resets any stored current TARGETDIR (in InstallScript installations), INSTALLDIR (in Basic MSI and InstallScript MSI installations), and SRCDIR entries.</li> </ul> <div>  </div> <p><b>Project</b> ▪ This constant applies to Basic MSI and InstallScript MSI projects:</p> <ul style="list-style-type: none"> <li>• <b>SRCINSTALLDIR</b>—This constant is obsolete. Use VAR_SRCTARGETDIR instead.</li> </ul> |

## Return Values

**Table 10** • VarRestore Return Values

| Return Value  | Description                                                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the previously saved values of the system variables were restored.                                                                                                                 |
| <b>&lt; 0</b> | Indicates that there are no values in storage to be restored. This error occurs if you call VarRestore without calling VarSave first, or if you call VarRestore more times than you call VarSave. |

## Additional Information

Each time you call **VarSave**, the InstallScript engine pushes the current values of the system variables onto an internal stack, which operates as a last in, first out storage area. This method allows you to stack a series of values in memory. You can then make calls to **VarRestore** to retrieve those values from the stack in the opposite order that you stored them.

For example, if you call **VarSave** three times with SRCTARGETDIR as its argument (without calling **VarRestore** in between those calls), there will be three sets of SRCDIR and TARGETDIR values on the stack. The first call to **VarRestore** with SRCTARGETDIR as its argument restores the values from the third call to **VarSave**. The next call to **VarRestore** restores the values from the second call to **VarSave**. The third call to **VarRestore** restores the values from the first call to **VarSave**. At that point, the stack is empty. To see a script fragment that illustrates this process, refer to [VarSave Stack Example](#).

## VarRestore Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the VarSave and VarRestore functions.
*
* This script starts by displaying the starting values of the
* system variables SRCDIR and INSTALLDIR. It then calls VarSave
* to save those values. Next, it assigns new values to SRCDIR
* and INSTALLDIR, and it displays those values. Finally, it
* calls VarRestore to restore the original values, which are
* then displayed.
*
\*-----*/

#define NEW_SOURCE_DIR "C:\\Source"
#define NEW_INSTALL_DIR "C:\\Target"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_VarRestore(HWND);

function ExFn_VarRestore(hMSI)
begin
    // Display the values of SRCDIR and INSTALLDIR.
    sprintfBox (INFORMATION, "Starting Source and Target Folders",
        "Source:\n\n%s\n\n Target:\n\n%s ",
        SRCDIR, INSTALLDIR);

    // Save the current values of SRCDIR and INSTALLDIR.
    VarSave (SRCTARGETDIR);
```

```

// Assign new values to SRCDIR and INSTALLDIR.
SRCDIR    = NEW_SOURCE_DIR;
INSTALLDIR = NEW_INSTALL_DIR;

// Display the values of SRCDIR and INSTALLDIR.
sprintfBox (INFORMATION, "New Source and Target Folders",
            "New Source:\n\n%s\n\n New Target:\n\n%s",
            SRCDIR, INSTALLDIR);

// Restore the old values.
VarRestore (SRCTARGETDIR);

// Display the values of SRCDIR and INSTALLDIR.
sprintfBox (INFORMATION, "Restored Source and Target Folders",
            "Source:\n\n%s\n\n Target:\n\n%s ",
            SRCDIR, INSTALLDIR);

end;

```

## VarSave

The **VarSave** function saves the current values of the system variables TARGETDIR (in InstallScript installations), INSTALLDIR ( in Basic MSI and InstallScript MSI installations), SRCDIR, or HKEYCURRENTROOTKEY, which are used by many other InstallScript functions. Call **VarSave** whenever you need to change the value of these system variables temporarily, for example, to set source and target directories before a call to **XCopyFile**. Afterwards, set those variables back to their previous values by calling **VarRestore**.

### Syntax

```
VarSave (nType);
```

## Parameters

**Table 11** • VarSave Parameters

| Parameter    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Return Values

**Table 12** • VarSave Return Values

| Return Value  | Description                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the current values of the system variables were saved.                                                                     |
| <b>&lt; 0</b> | Indicates that the values were not saved due to an internal error. This error should occur only if the system is low on available memory. |

## Additional Information

Each time you call **VarSave**, the InstallScript engine pushes the current values of the system variables onto an internal stack, which operates as a last in, first out storage area. This method allows you to stack a series of values in memory. You can then make calls to **VarRestore** to retrieve those values from the stack in the opposite order that you stored them.

For example, if you call **VarSave** three times with SRCTARGETDIR as its argument (without calling **VarRestore** in between those calls), there will be three sets of SRCDIR and TARGETDIR values on the stack. The first call to **VarRestore** with SRCTARGETDIR as its argument restores the values from the third call to **VarSave**. The next call to **VarRestore** restores the values from the second call to **VarSave**. The third call to **VarRestore** restores the values from the first call to **VarSave**. At that point, the stack is empty. To see a script fragment that illustrates this process, refer to [VarSave Stack Example](#).

## VarSave Example

**Note** - To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the VarSave and VarRestore functions.
*
* This script starts by displaying the starting values of the
* system variables SRCDIR and INSTALLDIR. It then calls VarSave
* to save those values. Next, it assigns new values to SRCDIR
* and INSTALLDIR, and it displays those values. Finally, it
* calls VarRestore to restore the original values, which are
* then displayed.
*
\*-----*/

#define NEW_SOURCE_DIR "C:\\Source"
#define NEW_INSTALL_DIR "C:\\Target"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_VarSave(HWND);

function ExFn_VarSave(hMSI)
begin
    // Display the values of SRCDIR and INSTALLDIR.
    sprintfBox (INFORMATION, "Starting Source and Target Folders",
        "Source:\n\n%s\n\n Target:\n\n%s ",
        SRCDIR, INSTALLDIR);

    // Save the current values of SRCDIR and INSTALLDIR.
    VarSave (SRCTARGETDIR);

    // Assign new values to SRCDIR and INSTALLDIR.
```

```

SRCDIR    = NEW_SOURCE_DIR;
INSTALLDIR = NEW_INSTALL_DIR;

// Display the values of SRCDIR and INSTALLDIR.
sprintfBox (INFORMATION, "New Source and Target Folders",
            "New Source:\n\n%s\n\n New Target:\n\n%s",
            SRCDIR, INSTALLDIR);

// Restore the old values.
VarRestore (SRCTARGETDIR);

// Display the values of SRCDIR and INSTALLDIR.
sprintfBox (INFORMATION, "Restored Source and Target Folders",
            "Source:\n\n%s\n\n Target:\n\n%s ",
            SRCDIR, INSTALLDIR);

end;

```

## VarSave Stack Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

// This script fragment illustrates how VarSave
// and VarRestore work with an internal stack
// to save and retrieve the values assigned to
// SRCDIR and INSTALLDIR

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_VarSave Stack(HWND);

function ExFn_VarSave Stack(hMSI)
begin

    // Store the starting values of SRCDIR and INSTALLDIR
    VarSave(SRCTARGETDIR);

    // Assign new values to SRCDIR and INSTALLDIR
    SRCDIR    = "E:\\";
    INSTALLDIR = "C:\\Program Files";

    // . . .

    // Store those values ("E:\\" and "C:\\Program Files")
    VarSave(SRCTARGETDIR);

    // Assign new values to SRCDIR and INSTALLDIR
    SRCDIR    = "A:\\";
    INSTALLDIR = "C:\\Windows";

    // . . .

```

```

// Store those new values ("A:\\\" and "C:\\Windows")
VarSave(SRCTARGETDIR);

// . . .

// Restore the values from the third call to VarSave
VarRestore(SRCTARGETDIR);

// SRCDIR is now "A:\\\"
// INSTALLDIR is now "C:\\Windows"

// . . .

// Restore the values from the second call to VarSave
VarRestore(SRCTARGETDIR);

// SRCDIR is now "E:\\\"
// INSTALLDIR is now "C:\\Program Files"

// . . .

// Restore the values from the first call to VarSave
VarRestore(SRCTARGETDIR);

// SRCDIR and INSTALLDIR now have their starting values.

end;

```

## VerCompare

The **VerCompare** function compares two strings that contain version information and returns whether the first one is less than, greater than, or equal to the second one.

**Important** • The format of the versions that you pass through the `szVersionInfo1` and `szVersionInfo2` parameters must be in the format **w.x.y.z**, where **w**, **x**, **y**, and **z** represent numbers. All four fields must be present; otherwise, **VerCompare** cannot successfully compare the two version strings.

For example, the following entries are valid `szVersionInfo1` and `szVersionInfo2` parameters:

- "1.0.0.0"
- "10.10.20.10"
- "3.21.01.2"

The following entries are not valid parameters:

- "1.20"
- "1.12.3"
- "2"

If one of the version strings has fewer than four fields, consider using the concatenate string operator (+) to add a decimal point and the number 0 as needed.

## Syntax

```
VerCompare ( szVersionInfo1, szVersionInfo2, nCompareFlag );
```

## Parameters

**Table 13** ▪ VerCompare Parameters

| Parameter             | Description                                                                                                                                |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szVersionInfo1</b> | Specify the first version string in the format <b>w.x.y.z</b> , where <b>w</b> , <b>x</b> , <b>y</b> , and <b>z</b> represent numbers.     |
| <b>szVersionInfo2</b> | Specify the second version string in the format <b>w.x.y.z</b> , where <b>w</b> , <b>x</b> , <b>y</b> , and <b>z</b> represent numbers.    |
| <b>nCompareFlag</b>   | Specify the predefined constant VERSION to indicate that you are comparing version numbers. No other values are allowed in this parameter. |

## Return Values

**Table 14** ▪ VerCompare Return Values

| Return Value                  | Description                                                               |
|-------------------------------|---------------------------------------------------------------------------|
| <b>EQUALS (2)</b>             | Indicates that the two strings are of equal value.                        |
| <b>LESS_THAN (1)</b>          | Indicates that the first string contains a value less than the second.    |
| <b>GREATER_THAN (0)</b>       | Indicates that the first string contains a value greater than the second. |
| <b>ISERR_GEN_FAILURE (-1)</b> | Indicates that the function could not compare the two strings.            |

## VerCompare Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the VerFindFileVersion and VerCompare functions.
*
* This script calls VerFindFileVersion to find the target file
* and retrieve its version information. If the specified
* target file is not found, the source file is copied to
* INSTALLDIR. If found, VerCompare is called to compare the
* version number of the EXAMPLE file found on the target
```

```

* system (the target file) to the version number of the file
* in SRCDIR (the source file). If the source file version
* number is newer than the target file, the target file is
* overwritten with the source file.
*
\*-----*/

#define EXAMPLE    "Stirinfc.dll"
#define SOURCE_VER "2.0.1.0"
#define TITLE      "VerCompare and VerFindFileVersion"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_VerFindFileVersion(HWND);

function ExFn_VerFindFileVersion(hMSI)
    STRING szFileName, svPath, svVersionNumber, szExistingVersion, szUpdateVersion;
    STRING szTitle, szMsg;
    NUMBER nResult, nCompareFlag;
begin
    // Set the file to be updated.
    szFileName = EXAMPLE;

    // Find szFileName on the target system and retrieve its version number.
    nResult = VerFindFileVersion(szFileName, svPath, svVersionNumber);

    if (nResult = FILE_NOT_FOUND) then
        // If szFileName not found, copy source file to INSTALLDIR.
        szMsg = "Unable to locate %s. Copying %s to %s.";
        sprintfBox (INFORMATION, TITLE, szMsg, szFileName, szFileName,
                    INSTALLDIR);

        CopyFile (szFileName, szFileName);
        abort;
    elseif (nResult = FILE_NO_VERSION) then

        // If no version number found, copy source file to svPath and exit.
        szMsg = "%s version number not found. Copying %s to %s.";

// If the source file is a more current version, install it.
if (nResult = GREATER_THAN) then
    szMsg      = "%s updated into the %s directory.";
    sprintfBox (INFORMATION, TITLE, szMsg, szFileName, INSTALLDIR);

    CopyFile (szFileName, szFileName);

// If the target file is a more current version, do not install.
elseif (nResult = LESS_THAN) then
    szMsg = "No need for an upgrade, the most current version of %s is " +
        "installed.";
    sprintfBox (INFORMATION, TITLE, szMsg, szFileName);

// If both the target and source versions are the same, do not install.
elseif (nResult = EQUALS) then
    MessageBox ("Versions are equal. No update needed.", INFORMATION);
endif;

end;

```

## VerFindFileVersion

The **VerFindFileVersion** function searches for a specified file and retrieves the file version and location.

# VerFindFileVersion

uses the following search algorithm

to find the file (searches the folders in the following order):

1. Windows folder
2. Windows system folder
3. The folder specified by the TARGETDIR system variable (in InstallScript installations) or the INSTALLDIR system variable (in Basic MSI and InstallScript MSI installations)
4. The folder from which Setup.exe is running

For information about the Windows system folder, see the documentation for the InstallScript system variable [WINSYSDIR](#).

**Note** ▪ When using **VerFindFileVersion**, you might need to set a value for **TARGETDIR** (in InstallScript installations) or **INSTALLDIR** (in Basic MSI and InstallScript installations) other than the value that is automatically set by the InstallScript engine. Since the function looks for the file in the **TARGETDIR** or **INSTALLDIR** folder, you might need to reset the value of the system variable temporarily to ensure that **VerFindFileVersion** finds the file. If you need to do this, use **VarSave** to save the value of **TARGETDIR** or **INSTALLDIR** before temporarily setting it to another folder. After the **VerFindFileVersion** function call, reset **TARGETDIR** or **INSTALLDIR** using **VarRestore**.

## Syntax

```
VerFindFileVersion ( szFileName, svPath, svVersionNumber );
```

## Parameters

**Table 15** • VerFindFileVersion Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>      | Specifies the unqualified name of the file whose version is to be obtained. Do not specify a drive designation or path in this parameter.                                                                                                                                       |
| <b>svPath</b>          | Returns the complete path (including the drive designation) to the folder in which the file resides.                                                                                                                                                                            |
| <b>svVersionNumber</b> | Returns the version number of the file in the following format:<br><br><div style="text-align: center;">&lt;major version&gt;.&lt;minor version&gt;</div> For example, if svVersionNumber returns 2.1.2.0, the major version number is 2.1 and the minor version number is 2.0. |

## Return Values

**Table 16** • VerFindFileVersion Return Values

| Return Value                | Description                                                                |
|-----------------------------|----------------------------------------------------------------------------|
| <b>0</b>                    | Indicates that the function successfully returned the version information. |
| <b>FILE_NO_VERSION (-8)</b> | Indicates that the file was found but did not contain version information. |
| <b>FILE_NOT_FOUND (-2)</b>  | Indicates that the file was not found.                                     |

## VerFindFileVersion Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the VerFindFileVersion and VerCompare functions.
*
* This script calls VerFindFileVersion to find the target file
* and retrieve its version information. If the specified
* target file is not found, the source file is copied to
* INSTALLDIR. If found, VerCompare is called to compare the
```

```

* version number of the EXAMPLE file found on the target
* system (the target file) to the version number of the file
* in SRCDIR (the source file). If the source file version
* number is newer than the target file, the target file is
* overwritten with the source file.
*
\*-----*/

#define EXAMPLE    "Stirinfc.dll"
#define SOURCE_VER "2.0.1.0"
#define TITLE      "VerCompare and VerFindFileVersion"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_VerFindFileVersion(HWND);

function ExFn_VerFindFileVersion(hMSI)
    STRING szFileName, svPath, svVersionNumber, szExistingVersion, szUpdateVersion;
    STRING szTitle, szMsg;

// If both the target and source versions are the same, do not install.
elseif (nResult = EQUALS) then
    MessageBox ("Versions are equal. No update needed.", INFORMATION);
endif;

end;

```

## VerGetFileLanguages

The **VerGetFileLanguages** function retrieves the list of languages supported by the file that is specified by szFile.

### Syntax

```
VerGetFileLanguages ( szFileName, listLanguages );
```

## Parameters

**Table 17** ▪ VerGetFileLanguages Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>    | Specifies the fully qualified name of the file whose list of supported languages is to be retrieved.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>listLanguages</b> | <p>Returns the list of numeric language codes and code page IDs of the supported languages. Each list element is a 32-bit integer whose low-order word contains the supported language code and whose high-order word contains the corresponding code page ID, which can be extracted with the functions <a href="#">LOWORD</a> and <a href="#">HIWORD</a>.</p> <p>The number list identified by listLanguages must already have been initialized by a call to <a href="#">ListCreate(NUMBERLIST)</a>.</p> |

## Return Values

**Table 18** ▪ VerGetFileLanguages Return Values

| Return Value               | Description                                                          |
|----------------------------|----------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully retrieved the list of supported languages. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to retrieve the list of supported languages.     |

## VerGetFileLanguages Example

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the VerGetFileLanguages function.
 *
 \*-----*/

function OnBegin()
    number nListGetItem, nvLanguageInfo, nLanguageCode, nCodePage;
    string szFileName;
    LIST listLanguages, listLanguageCodes, listCodePages;
begin
    // Get file language information.

```

```

szFileName = "C:\\Program Files\\Internet Explorer\\Iexplore.exe";
listLanguages = ListCreate( NUMBERLIST );
VerGetFileLanguages( szFileName, listLanguages );

// Extract language codes and code page IDs
// from list items and add to new lists.
listLanguageCodes = ListCreate( NUMBERLIST );
listCodePages = ListCreate( NUMBERLIST );
nListGetItem = ListGetFirstItem( listLanguages ,nvLanguageInfo);
while nListGetItem=0
    nLanguageCode = LOWORD( nvLanguageInfo );
    ListAddItem( listLanguageCodes, nLanguageCode, AFTER );
    nCodePage = HIWORD( nvLanguageInfo );
    ListAddItem( listCodePages, nCodePage, AFTER );
    nListGetItem = ListGetNextItem( listLanguages ,nvLanguageInfo);
endwhile;
end;

```

## VerGetFileVersion

The **VerGetFileVersion** function retrieves the numeric version information of the specified file.

**Note** - Although InstallScript's file version functions take version information in string format, the version information they reference in a file is the numeric version information. A file's string version information is not inspected or returned by InstallScript functions. Further, when Windows Explorer displays a file's properties, it shows the string version information, which might not be equivalent to the file's numeric version information. For that reason, the value returned in `svVersionNumber` by `VerGetFileVersion` might not match the version information displayed by Windows Explorer.

For more about file version information, consult the Windows documentation.

### Syntax

```
VerGetFileVersion ( szFileName, svVersionNumber );
```

## Parameters

**Table 19** ▪ VerGetFileVersion Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>      | Specifies the fully qualified name of the file whose numeric version information is to be retrieved.                                                                                                                                                                                            |
| <b>svVersionNumber</b> | <p>Returns the numeric version information as a string in the following format:</p> <p style="text-align: center;">&lt;major version&gt;.&lt;minor version&gt;</p> <p>For example, if svVersionNumber returns 2.1.2.0, the major version number is 2.1 and the minor version number is 2.0.</p> |

## Return Values

**Table 20** ▪ VerGetFileVersion Return Values

| Return Value                | Description                                                                |
|-----------------------------|----------------------------------------------------------------------------|
| <b>0</b>                    | Indicates that the function successfully returned the version information. |
| <b>FILE_NOT_FOUND (-2)</b>  | Indicates that the specified file was not found.                           |
| <b>FILE_NO_VERSION (-8)</b> | Indicates that the file was found but did not contain version information. |

## VerGetFileVersion Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the VerGetFileVersion function.
*
* The script below calls VerGetFileVersion to retrieve the
* version number of the Windows Notepad. The information is
* displayed in a message box.
*
\*-----*/

#define EXAMPLE_FILE WINDIR ^ "Notepad.exe"
#define TITLE_TEXT "VerGetFileVersion Example"

```

```
// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_VerGetFileVersion(HWND);

function ExFn_VerGetFileVersion(hMSI)
    NUMBER nResult;
    STRING szFile, szPath, szMsg, svVersionNumber;
begin

    // Get the version number of the specified file.
    nResult = VerGetFileVersion(EXAMPLE_FILE, svVersionNumber);

    // Report the results of VerGetFileVersion.
    if (nResult = FILE_NO_VERSION) then
        szMsg = EXAMPLE_FILE + " does not contain version information.";
        MessageBox (szMsg, INFORMATION);
    elseif (nResult = FILE_NOT_FOUND) then
        szMsg = EXAMPLE_FILE + " could not be found.";
        MessageBox (szMsg, INFORMATION);
    else
        szMsg = "The version number of %s is %s";
        sprintfBox (INFORMATION, TITLE_TEXT, szMsg,
            EXAMPLE_FILE, svVersionNumber);
    endif;

end;
```

## VerProductCompareVersions

**Project** - This information applies to InstallScript projects.

The **VerProductCompareVersions** function compares version information and returns a value indicating the result of the comparison.

### Syntax

```
VerProductCompareVersions ( );
```

### Parameters

None.

## Return Values

**Table 21** ▪ VerProductCompareVersions Return Values

| Return Value                                      | Description                                                                                                                                                              |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VERSION_COMPARE_RESULT_NOT_INSTALLED</b>       | No version of the product is installed or the installed version was not found (IFX_INSTALLED_VERSION is a null string).                                                  |
| <b>VERSION_COMPARE_RESULT_SAME</b>                | The update setup's version is the same as the version currently installed on the target system.                                                                          |
| <b>VERSION_COMPARE_RESULT_OLDER</b>               | The update setup's version is older than the version currently installed on the target system.                                                                           |
| <b>VERSION_COMPARE_RESULT_NEWER_NOT_SUPPORTED</b> | The update setup's version is newer than the version currently installed on the target system, but the currently installed version is not supported by the update setup. |
| <b>VERSION_COMPARE_RESULT_NEWER</b>               | The update setup's version is newer than the version currently installed on the target system, and the currently installed version is supported by the update setup.     |
| <b>&lt; ISERR_SUCCESS</b>                         | The function failed.                                                                                                                                                     |

## Comments

The function compares the values of the system variables **IFX\_INSTALLED\_VERSION** and **IFX\_PRODUCT\_VERSION** to determine if the version currently installed on the target system is older than the update setup's version; if so, the function compares the values of the system variables **IFX\_INSTALLED\_VERSION** and **IFX\_SUPPORTED\_VERSIONS** to determine if the update setup applies to the currently installed version.

VerProductCompareVersions is called by the default code for the OnSetUpdateMode and OnUpdateUIBefore event handler functions.

# VerProductGetInstalledVersion

**Project** ▪ This information applies to InstallScript projects.

The **VerProductGetInstalledVersion** function returns in svVersionInstalled the string equivalent of the data in the Version value of the application uninstallation registry key if that data is a packed DWORD.

## Syntax

```
VerProductGetInstalledVersion ( svVersionInstalled );
```

## Parameters

**Table 22** • VerProductGetInstalledVersion Parameters

| Parameter                 | Description                                                                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>svVersionInstalled</b> | Returns the string equivalent of the data in the application uninstallation registry key's Version value. If the function fails, the value of svVersionInstalled is not changed. |

## Return Values

**Table 23** • VerProductGetInstalledVersion Return Values

| Return Value               | Description                                                                                                                                    |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function successfully retrieved the installed version information.                                                                         |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed to retrieve the installed version information; the registry key or value does not exist or the data is not a packed DWORD. |

# VerProductIsVersionSupported

**Project** • This information applies to InstallScript projects.

The **VerProductIsVersionSupported** function checks whether the version string in szVersionCheck is one of the versions in szVersionSupported.

## Syntax

```
VerProductIsVersionSupported ( szVersionCheck, szVersionSupported );
```

## Parameters

**Table 24** ▪ VerProductIsVersionSupported Parameters

| Parameter                 | Description                                                                                                                                                               |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szVersionCheck</b>     | Specifies a version string in packed DWORD format (for example, the initial value of the system variable <code>IFX_PRODUCT_VERSION</code> ).                              |
| <b>szVersionSupported</b> | Specifies a pipe()-delimited list of version strings in packed DWORD format (for example, the initial value of the system variable <code>IFX_SUPPORTED_VERSIONS</code> ). |

## Return Values

**Table 25** ▪ VerProductIsVersionSupported Return Values

| Return Value | Description                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------------------|
| <b>TRUE</b>  | szVersionCheck is one of the versions in szVersionSupported, or szVersionSupported is a null string (""). |
| <b>FALSE</b> | szVersionCheck is not one of the versions in szVersionSupported.                                          |

# VerProductNumToStr

**Project** ▪ This information applies to InstallScript projects.

The **VerProductNumToStr** function returns in svVersion the version string corresponding to the packed DWORD specified in nVersion.

## Syntax

```
VerProductNumToStr ( svVersion, nVersion );
```

## Parameters

**Table 26** ▪ VerProductNumToStr Parameters

| Parameter        | Description                                                                                         |
|------------------|-----------------------------------------------------------------------------------------------------|
| <b>svVersion</b> | Returns the string equivalent, in packed DWORD format, of nVersion.                                 |
| <b>nVersion</b>  | Specifies version information as a four-byte value, that is, a number in the range 0 to 4294967295. |

## Return Values

**Table 27** ▪ VerProductNumToStr Return Values

| Return Value               | Description             |
|----------------------------|-------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function succeeded. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed.    |

# VerProductStrToNum

**Project** ▪ This information applies to InstallScript projects.

The **VerProductStrToNum** function returns in nvVersionResult the packed DWORD version information corresponding to the string specified in svVersion.

## Syntax

```
VerProductStrToNum ( nvVersionResult, szVersion );
```

## Parameters

**Table 28** • VerProductStrToNum Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvVersionResult</b> | Returns the packed DWORD version information.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>szVersion</b>       | <p>Specifies version information in string form. The function fails unless szVersion meets all of the following conditions:</p> <ul style="list-style-type: none"> <li>• szVersion is in the format major.minor.build or major.minor.build.release (release is ignored when determining nvVersionResult).</li> <li>• major and minor are the string equivalents of numbers in the range 0 to 255.</li> <li>• build is the string equivalent of a number in the range 0 to 65535.</li> </ul> |

## Return Values

**Table 29** • VerProductStrToNum Return Values

| Return Value               | Description             |
|----------------------------|-------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The function succeeded. |
| <b>&lt; ISERR_SUCCESS</b>  | The function failed.    |

# VerProductVerFromVerParts

**Project** • This information applies to InstallScript projects.

The **VerProductVerFromVerParts** function retrieves the packed DWORD that corresponds to the version parts specified by nVersionMajor, nVersionMinor, and nVersionBuild.

## Syntax

```
VerProductVerFromVerParts ( nvVersion, nVersionMajor, nVersionMinor, nVersionBuild );
```

## Parameters

**Table 30** • VerProductVerFromVerParts Parameters

| Parameter            | Description                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nVersion</b>      | Returns the four-byte value that corresponds to the version parts specified by nVersionMajor, nVersionMinor, and nVersionBuild.                 |
| <b>nVersionMajor</b> | Specifies the first byte of version information. VerProductVerFromVerParts fails if this value is less than zero (0) or greater than 255.       |
| <b>nVersionMinor</b> | Specifies the second byte of version information. VerProductVerFromVerParts fails if this value is less than zero (0) or greater than 255.      |
| <b>nVersionBuild</b> | Specifies the last two bytes of version information. VerProductVerFromVerParts fails if this value is less than zero (0) or greater than 65535. |

## Return Values

**Table 31** • VerProductVerFromVerParts Return Values

| Return Value               | Description                            |
|----------------------------|----------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | Indicates that the function succeeded. |
| <b>&lt; ISERR_SUCCESS</b>  | Indicates that the function failed.    |

# VerProductVerPartsFromVer

**Project** • This information applies to InstallScript projects.

The **VerProductVerPartsFromVer** function retrieves as separate numeric values the version parts of the packed DWORD specified by nVersion.

## Syntax

```
VerProductVerPartsFromVer ( nVersion, nvVersionMajor, nvVersionMinor, nvVersionBuild );
```

## Parameters

**Table 32** ▪ VerProductVerPartsFromVer Parameters

| Parameter             | Description                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------|
| <b>nVersion</b>       | Specifies version information as a four-byte value, that is, a number in the range 0 to 4294967295. |
| <b>nvVersionMajor</b> | Returns the first byte of nVersion.                                                                 |
| <b>nvVersionMinor</b> | Returns the second byte of nVersion.                                                                |
| <b>nvVersionBuild</b> | Returns the last two bytes of nVersion.                                                             |

## Return Values

**Table 33** ▪ VerProductVerPartsFromVer Return Values

| Return Value         | Description                                 |
|----------------------|---------------------------------------------|
| <b>ISERR_SUCCESS</b> | This function always returns ISERR_SUCCESS. |

# VerSearchAndUpdateFile

The **VerSearchAndUpdateFile** function searches for the specified file and installs a newer version of the file if necessary. If the function finds the file, it compares the version number of the existing file to the version number of the new file. If the existing file is older, it is replaced with the new file. The new file must be in the directory specified by the system variable SRCDIR. If the function does not find an existing file, it copies the new file to the target system. Windows decides where the file is installed depending on the type of the file. For example, DLLs and system drivers are installed in the Windows system folder. For information about the Windows system folder, see the documentation for the InstallScript system variable **WINSYSDIR**.

**VerFindFileVersion** uses the following search algorithm to find the file (searches the folders in the following order):

1. Windows folder
2. Windows system folder
3. The folder specified by the TARGETDIR system variable (in InstallScript installations) or the INSTALLDIR system variable (in Basic MSI or InstallScript MSI installations)
4. The folders specified by the PATH environment variable
5. The folder from which Setup.exe is running

**Note** ▪ For file transfer, an alternative to **VerSearchAndUpdateFile** is **XCopyFile**—which can do check version, mark locked .dll and .exe files for update after system reboot, and increment registry reference counters for shared .dll and .exe files.

## Syntax

```
VerSearchAndUpdateFile ( szFileName, nUpdateFlag, svInstalledFile );
```

## Parameters

**Table 34** • VerSearchAndUpdateFile Parameters

| Parameter              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>      | Specifies the unqualified name of the file to install. Do not specify a drive designation or path in this parameter.                                                                                                                                                                                                                                                                                                                                                                               |
| <b>nUpdateFlag</b>     | <p>Specifies whether the file should be updated unconditionally or only if the version of the file found on the target system is older than the version of the file that you have shipped. Pass one of the following predefined constants in this parameter:</p> <ul style="list-style-type: none"> <li>• <b>VER_UPDATE_COND</b>—Updates the existing file only if it is an older version.</li> <li>• <b>VER_UPDATE_ALWAYS</b>—Updates the existing file even if it is a newer version.</li> </ul> |
| <b>svInstalledFile</b> | Returns the fully qualified name of the file installed by the function. If the file you want to replace is in use, the file is installed to the same directory with a slightly different name. The file is renamed with a tilde (~) character in the first character of the extension. For example, if you are installing the file Shell.dll and the file is locked, the file is copied as Shell.~ll. The name is returned in this variable.                                                       |

## Return Values

**Table 35** • VerSearchAndUpdateFile Return Values

| Return Value                  | Description                                                                                                                                                                                          |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FILE_INSTALLED (0)</b>     | Function was successful in installing the file.                                                                                                                                                      |
| <b>FILE_IS_LOCKED (-4)</b>    | Indicates that the file is in use by Windows and cannot be replaced. The new file is copied to the same directory with a new name.                                                                   |
| <b>FILE_NO_VERSION (-8)</b>   | Indicates that the file was found, but it did not contain version information. File update is not performed.                                                                                         |
| <b>FILE_RD_ONLY (-5)</b>      | Indicates that the existing file is write protected. The script should reset the read-only flag of the destination file before proceeding with the setup and then attempt to install the file again. |
| <b>FILE_SRC_OLD (-7)</b>      | Indicates that the file to install has the same date or is older than the preexisting file.                                                                                                          |
| <b>OUT_OF_DISK_SPACE (-6)</b> | Indicates that the function cannot create the file due to insufficient disk space on the destination drive. File update is not performed.                                                            |
| <b>VER_DLL_NOT_FOUND (-3)</b> | Indicates Ver.dll was not found. File update is not performed.                                                                                                                                       |

**Table 35** • VerSearchAndUpdateFile Return Values (cont.)

| Return Value              | Description                                                            |
|---------------------------|------------------------------------------------------------------------|
| <b>OTHER_FAILURE (-1)</b> | Indicates an unspecified error occurred. File update is not performed. |

## VerSearchAndUpdateFile Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the VerSearchAndUpdateFile function.
*
* The first call to VerSearchAndUpdateFile replaces the file
* specified by the constant UPDATE_FILE1 regardless of the
* version on the target system.
*
* The second call to VerSearchAndUpdateFile replaces the file
* specified by the constant UPDATE_FILE2 only if the version
* in the source directory is newer than the version in the
* target directory.
*
\*-----*/

#define UPDATE_FILE1  "Example.txt"
#define UPDATE_FILE2  "Readme.txt"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_VerSearchAndUpdateFile(HWND);

function ExFn_VerSearchAndUpdateFile(hMSI)
    STRING szFileName, svInstalledFile, szTitle, szMsg;
    NUMBER nUpdateFlag, nResult;
    BOOL    bDone;
begin

    // Set up title and message parameters for call
    // to VerSearchAndUpdateFile.
    szTitle = "VerSearchAndUpdateFile Example";
    szMsg    = " was successfully updated.";

    // Update UPDATE_FILE1 regardless of version number.
    if (VerSearchAndUpdateFile (UPDATE_FILE1, VER_UPDATE_ALWAYS,
                               svInstalledFile) = 0) then
        SprintfBox (INFORMATION, szTitle, UPDATE_FILE1 + szMsg);
    endif;

```

```

// Set indicator to control loop exit.
bDone = FALSE;

// Begin the while loop.
while (bDone = FALSE)
    // Update UPDATE_FILE2 only if existing file is older.
    nResult = VerSearchAndUpdateFile (UPDATE_FILE2, VER_UPDATE_COND,
                                      svInstalledFile);

    switch (nResult)
    case 0:
        // VerSearchAndUpdate successful.
        sprintfBox (INFORMATION, szTitle, UPDATE_FILE2 + szMsg);
        bDone = TRUE;
    // The target file does not have a version number.
    case FILE_NO_VERSION:
        // Ask the user if the file should be updated regardless.
        if (AskYesNo ("Version number was not found.\nDo you still wish " +
                     "to update " + UPDATE_FILE2 + "?", YES) = YES) then
            // Update the file UPDATE_FILE2 regardless of version number.
            VerSearchAndUpdateFile (UPDATE_FILE2, VER_UPDATE_ALWAYS,
                                    svInstalledFile);

            bDone = TRUE;
        else
            bDone = TRUE;
        endif;

    // The target file is locked.
    case FILE_IS_LOCKED:
        MessageBox ("The target file is locked.\n\nPlease close all " +
                    "programs and run Setup again.", INFORMATION);

        bDone = TRUE;
    // The target file is read-only.
    case FILE_RD_ONLY:
        // Ask the user if Setup should remove the read-only attribute.
        if (AskYesNo ("File is read-only.\nShould Setup remove the " +
                     "write-protection of " + UPDATE_FILE2 + "?", YES) = YES) then
            // Change the attribute of the target file to normal.
            SetFileInfo (svInstalledFile, FILE_ATTRIBUTE, FILE_ATTR_NORMAL, "");
            bDone = FALSE;
        else
            bDone = TRUE;
        endif;
    // The target disk does not have enough space.
    case OUT_OF_DISK_SPACE:
        MessageBox ("You need more free space for this update.", SEVERE);

        bDone = TRUE;
    // The required VER.DLL file was not found.
    case VER_DLL_NOT_FOUND:
        MessageBox ("VER.DLL was not found.", SEVERE);

        bDone = TRUE;
    // Some other error occurred.
    case OTHER_FAILURE:
        MessageBox ("Update has failed.", SEVERE);

        bDone = TRUE;
    default:

```

```

        bDone = TRUE;
    endswitch;

    endwhile;

end;

```

## VerUpdateFile

The **VerUpdateFile** function uses the version information of a specified file to determine whether or not to install the file on the target directory. VerUpdateFile gets the file name specified in szFileName.

VerFindFileVersion uses the following search algorithm to find the file (searches the folders in the following order):

1. Windows folder
2. Windows system folder
3. The folder specified by the TARGETDIR system variable (in InstallScript installations) or the INSTALLDIR system variable (in Basic MSI or InstallScript MSI installations)
4. The folders specified by the PATH environment variable
5. The folder from which Setup.exe is running

VerUpdateFile then compares the version of the file with the same name in SRCDIR (the source file), if it exists, with the version of the target file. If the source file has a more recent version number than the target file, the target file is replaced by the source file. If the target file does not exist, InstallShield copies the source file to the target location.

When the SHAREDFILE or LOCKEDFILE option is used in the parameter nUpdateFlag and .dll or .exe files to be updated are in use by the system, renamed copies of the source files are transferred to the target system and the system variable BATCH\_INSTALL is set to TRUE. Then, when **RebootDialog** or **SdFinishReboot** is called at the end of the setup and the system is restarted, the locked files are updated. For more information on updating locked files, see [RebootDialog](#) and [SdFinishReboot](#). The system variable BATCH\_INSTALL can be tested to determine if locked .dll or .exe files were encountered. You cannot use the SHAREDFILE and LOCKEDFILE options simultaneously-you must use one or the other.

For file transfer, preferable alternatives to VerUpdateFile may be XCopyFile, which can perform version checking, mark locked .dll and .exe files for update after system reboot, and increment registry reference counters for shared .dll and .exe files.

### Syntax

```
VerUpdateFile ( szFileName, nUpdateFlag, svInstalledFilePath );
```

## Parameters

**Table 36** • VerUpdateFile Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>  | <p>Specifies the qualified or unqualified name of the file to update. If the name is unqualified (that is, if it does not include a drive designation or path), InstallShield searches the Windows or Win95 directory, the System directory, the directories specified by the PATH environment variable, and then the path of the InstallShield executable file for a matching file. VerUpdateFile takes the file name portion of szFileName and uses it to identify the file in SRCDIR that is used as the source file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>nUpdateFlag</b> | <p>Specifies whether the file is updated unconditionally or updated only if the version of the target file found is older than the version of the source file. Pass one of the following predefined constants in this parameter. You can combine the constant SHAREDFILE with one of the other constants using the bitwise OR operator (   ). However, you cannot combine SHAREDFILE and LOCKEDFILE.</p> <ul style="list-style-type: none"> <li> <b>LOCKEDFILE</b>—Causes VerUpdateFile to record locked .dll and .exe files for update when Windows or the system is rebooted. A locked file is a file that is in use by an application or the system when InstallShield attempts to access or update the file. The LOCKEDFILE option works like SHAREDFILE except that LOCKEDFILE does not create registry entries or modify the registry reference counter. You cannot use the LOCKEDFILE option when using the SHAREDFILE option. There are some unshared files (such as shell extensions) for which the script writer does not want a registry entry and reference counter. These files should never be uninstalled, except by the application itself. LOCKEDFILE allows VerUpdateFile to handle locked files that are not shared. </li> <li> <b>SHAREDFILE</b>—Combines shared and locked file handling by causing VerUpdateFile to treat all files as shared, and to record locked .dll and .exe files for update when Windows or the system restarts. See RebootDialog and SdFinishReboot. </li> </ul> <p>The SHAREDFILE option causes VerUpdateFile to treat all files as shared files and increment the registry reference counter by one when the file exists in the target directory and it has a reference count greater than 0. If the shared file does not exist in the target directory and it has no reference counter, InstallShield creates the counter and sets it to 1. If the shared file already exists in the target directory but has no reference counter, InstallShield creates the counter and initializes it to 2 as a precaution against accidental removal during uninstallation.</p> |

**Table 36** • VerUpdateFile Parameters (cont.)

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nUpdateFlag (continued)</b> | <ul style="list-style-type: none"> <li> <b>SELFREGISTER</b>—Carries out the self-registration process immediately, when using the “non-batch method” of installing self-registering files.<br/><br/>           If you have called <b>Enable</b>(SELFREGISTERBATCH), this option queues up self-registering files for registration. The files are registered once <b>Do</b>(SELFREGISTRATIONPROCESS) is called, when using the “batch method” of installing self-registering files.<br/><br/>           Always use SELFREGISTER together with the constant SHAREDFILE, using the bitwise OR operator (   ).         </li> <li> <b>VER_UPDATE_ALWAYS</b>—Updates the file regardless of the version numbers.         </li> <li> <b>VER_UPDATE_COND</b>—Updates the file only if the file being replaced is an older version.         </li> </ul> |
| <b>svInstalledFilePath</b>     | <p>Returns the fully qualified name of the file that was installed. If the file you want to replace is in use, the file is installed to the same directory with a modified name. InstallShield uses a tilde (~) character to replace the first character of the file's extension.</p> <p>For example, if you are updating the file Shell.dll and the target file is locked, the source file is copied to the target directory as Shell.~ll. This name is returned in the parameter svInstalledFilePath.</p> <p>If the SHAREDFILE option is used in the parameter nUpdateFlag and locked files are properly committed for update when Windows or the system restarts, the ~ modified name versions of the files are deleted when the update takes place.</p>                                                                                    |

## Return Values

**Table 37** ▪ VerUpdateFile Return Values

| Return Value                  | Description                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FILE_INSTALLED (0)</b>     | Indicates that the function successfully installed the file. This constant is equal to 0 (zero). All other return values are less than zero (< 0).                                          |
| <b>FILE_IS_LOCKED (-4)</b>    | Indicates that the existing file is in use by Windows and cannot be replaced. The new file is copied to the same directory with a new name, as described above.                             |
| <b>FILE_NO_VERSION (-8)</b>   | Indicates that the file was found, but it did not contain version information in it. File update is not performed.                                                                          |
| <b>FILE_RD_ONLY (-5)</b>      | Indicates that the existing file is write-protected. You must reset the read-only bit in the destination file before proceeding with the setup, and then attempt to install the file again. |
| <b>FILE_SRC_EQUAL (-9)</b>    | Indicates that the file you want to install has the same version as the existing file. File update is not performed if the VER_UPDATE_COND flag is set.                                     |
| <b>FILE_SRC_OLD (-7)</b>      | Indicates that the file you want to install is older than the existing file. File update is not performed if the VER_UPDATE_COND flag is set.                                               |
| <b>OUT_OF_DISK_SPACE (-6)</b> | Indicates that the function cannot create the file due to insufficient disk space on the destination drive. File update is not performed.                                                   |
| <b>-51</b>                    | A self-registering file did not register successfully.                                                                                                                                      |
| <b>OTHER_FAILURE (-1)</b>     | Indicates an unspecified error occurred. File update is not performed.                                                                                                                      |

## VerUpdateFile Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the VerUpdateFile function.
*
* This script calls VerUpdateFile twice to update a Windows
* accessory.
*
\*-----*/

```

```

#define APPFILE "Notepad.exe"
#define TITLE   "VerUpdateFile Example"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_VerUpdateFile(HWND);

function ExFn_VerUpdateFile(hMSI)
    STRING svInstalledFilePath, szTitle, szMsg;
    NUMBER nResult;
    BOOL    bDone;
begin

    // Update the file regardless of file version.
    nResult = VerUpdateFile (APPFILE, VER_UPDATE_ALWAYS, svInstalledFilePath);

    if (nResult < 0) then
        MessageBox ("First call to VerUpdateFile failed.", SEVERE);
    else
        szMsg = "%s successfully updated.";
        SprintfBox (INFORMATION, TITLE, szMsg, APPFILE);
    endif;

    // Update the files only if the target files are more recent.
    nResult = VerUpdateFile (APPFILE, VER_UPDATE_COND, svInstalledFilePath);

    if (nResult < 0) then
        MessageBox ("Second call to VerUpdateFile failed.", SEVERE);
    endif;

end;

```

## WaitForApplication

The **WaitForApplication** function waits for a running application to terminate before returning.

If the function fails to wait for the application to terminate before returning, verify that the application does not terminate until other sub-applications launched by the application terminate. The **WaitForApplication** function monitors the process handle of the specified application; if the application passes control to a secondary application or process and then terminates, the function returns immediately.

### Syntax

```

WaitForApplication( byval number hProcess, byval number dwProcessId, byval number nTimeOut, byval number
    nOptions );

```

## Parameters

**Table 38** ▪ WaitForApplication Parameters

| Parameter          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hProcess</b>    | Specifies the process handle of the running process for which to wait. (If the application was launched with <b>LaunchAppAndWait</b> or <b>LaunchApp</b> , this handle is returned in the LAAW_PROCESS_INFORMATION.hProcess member.)                                                                                                                                                                                                                                                       |
| <b>dwProcessId</b> | <p>Specifies the process ID of the running process for which to wait. You need to specify a non-zero value for this parameter only if you specify LAAW_OPTION_WAIT_INCL_CHILD in nOptions.</p> <p>If the application was launched with <b>LaunchAppAndWait</b> or <b>LaunchApp</b> and the process ID can be determined (as described for the description of <a href="#">LAAW_OPTION_WAIT_INCL_CHILD</a>), this handle is returned in the LAAW_PROCESS_INFORMATION.dwProcessId member.</p> |
| <b>nTimeout</b>    | Specifies the maximum amount of time (in milliseconds) to wait for the application to complete before returning. If this amount of time passes before the application terminates, the function ends the wait and returns failure. You can specify INFINITE to indicate that the function should wait indefinitely. (You can also pass the LAAW_PARAMETERS.nTimeout value to mimic the behavior of the <b>LaunchAppAndWait</b> function.)                                                   |

**Table 38** • WaitForApplication Parameters (cont.)

| Parameter       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOptions</b> | <p>Pass one of the following predefined constants in this parameter. You can combine these constants by using the bitwise OR operator (   ), with the following exceptions: you cannot combine LAAW_OPTION_NOWAIT with LAAW_OPTION_WAIT.</p> <ul style="list-style-type: none"> <li>● <b>LAAW_OPTION_WAIT</b>—Specifies that the function should wait until the specified application has terminated.</li> </ul> <p></p> <p><b>Note</b> • If the specified applications fails to terminate and nOptions is set to LAAW_OPTION_WAIT (and nTimeout is set to INFINITE), the installation will wait indefinitely for the launched application to complete.</p> <ul style="list-style-type: none"> <li>● <b>LAAW_OPTION_NOWAIT</b>—Specifies that the function should return immediately.</li> <li>● <b>LAAW_OPTION_USE_CALLBACK</b>—Causes the function to call the OnLaunchAppAndWaitCallback event every second, or whatever interval you set for the LAAW_PARAMETERS.nCallbackInterval member, while waiting for the application to terminate.</li> <li>● <b>LAAW_OPTION_WAIT_INCL_CHILD</b>—Indicates that the function should wait for the launched application and any of its direct child processes.</li> </ul> <p>When LAAW_OPTION_WAIT_INCL_CHILD is used, the function detects and waits for only direct child processes of the launched process—not for any additional child processes that are launched by child processes of the initially launched process.</p> <p>Note that to detect and wait for child processes with LAAW_OPTION_WAIT_INCL_CHILD, the function must receive or be able to determine the process ID of the launched process. Therefore, in order for this option to work, if dwProcessId is not specified, the Windows API <b>GetProcessId</b> must be available on the system so that the function can determine the process ID. According to the Windows API documentation, <b>GetProcessId</b> is available on Windows XP SP1 and later and Windows Server 2003 and later. If this API is not available, LAAW_OPTION_WAIT_INCL_CHILD behaves as LAAW_OPTION_WAIT.</p> <p>You can specify any <b>LaunchApplication</b> option; however, only the aforementioned options will have any effect.</p> |

## Return Values

**Table 39** ▪ WaitForApplication Return Values

| Return Value               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>&gt;= ISERR_SUCCESS</b> | The application terminated and the function returned as a result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>&lt; ISERR_SUCCESS</b>  | <p>The function returned as a result of something other than the application terminating. You can check the value of LAAW_PARAMETERS.nWaitResult to determine additional information:</p> <ul style="list-style-type: none"> <li>• <b>WAIT_OBJECT_0</b>—Indicates that the application terminated.</li> <li>• <b>WAIT_OBJECT_0 + 1</b>—Indicates that the installation received a message to terminate.</li> <li>• <b>WAIT_TIMEOUT</b>—Indicates that the timeout interval was reached or the callback function returned LAAW_CALLBACK_RETURN_END_WAIT. Check the value of LAAW_PARAMETERS.bCallbackEndedWait to determine which ended the wait.</li> </ul> |

## WaitOnDialog

The **WaitOnDialog** function displays a custom dialog. You can write your script to handle different responses from the user based on the return value from this function.

### Syntax

```
WaitOnDialog ( szDlgName );
```

## Parameters

**Table 40** ▪ WaitOnDialog Parameters

| Parameter        | Description                                |
|------------------|--------------------------------------------|
| <b>szDlgName</b> | Specifies the ID of the dialog to display. |

## Return Values

**Table 41** ▪ WaitOnDialog Return Values

| Return Value             | Description                                                             |
|--------------------------|-------------------------------------------------------------------------|
| <b>dialog control ID</b> | The ID of the dialog control that received the WM_COMMAND message.      |
| <b>IDCANCEL (2)</b>      | This message is received as a signal that the dialog is about to close. |
| <b>DLG_ERR (-1)</b>      | This message is received if any errors occurred.                        |
| <b>DLG_INIT (-100)</b>   | This message is received immediately before the dialog is displayed.    |

## Additional Information

To enable end users to cancel the installation by clicking the close button in the upper-right corner of the InstallScript dialog, the dialog must have a button control whose Control Identifier property is set to 2. For more information, see [Using InstallScript to Implement Custom Dialogs](#).

## WaitOnDialog Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the DefineDialog, WaitOnDialog, EndDialog, and
* ReleaseDialog functions.
*
* This script opens a simple custom dialog that displays
* a bitmap. The dialog can be closed with any of three
* buttons: Back, Next, or Cancel.
*
* The "custom" dialog used in this script is actually the
* InstallShield Sd dialog that is displayed by the built-in
* function SdBitmap. Because this dialog is stored in
* the file _isres.dll, which is already compressed in
* the installation, it can be used in a script as a custom
* dialog.
```

```

*
* In order to use this dialog as a custom dialog, the
* script first defines it by calling DefineDialog. It then
* displays the dialog by calling WaitOnDialog. When an event
* ends dialog processing, EndDialog is called to close the
* dialog. Then the dialog is released from memory by
* a call to ReleaseDialog.
*
\*-----*/

// Dialog and control IDs.
#define RES_DIALOG_ID      12027  // ID of dialog itself
#define RES_PBUT_NEXT      1      // ID of Next button
#define RES_PBUT_CANCEL    9      // ID of Cancel button
#define RES_PBUT_BACK      12     // ID of Back button

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_WaitOnDialog(HWND);

function ExFn_WaitOnDialog(hMSI)
    STRING  szDialogName, szDLLName, szDialog;

        // for this dialog and replace %P, %VS, %VI with
        // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
        // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724
        // and 202.
        hwndDlg = CmdGetHwndDlg(szDialogName);
        SdGeneralInit(szDialogName, hwndDlg, 0, "");
    case RES_PBUT_CANCEL:
        // The user clicked the Cancel button.
        Do (EXIT);
    case RES_PBUT_NEXT:
        bDone = TRUE;
    case RES_PBUT_BACK:
        bDone = TRUE;
    endswitch;

until bDone;

// Close the dialog.
EndDialog (szDialogName);

// Free the dialog from memory.
ReleaseDialog (szDialogName);

end;

```

## Welcome

**Project** • This information applies to the following project types:

- *InstallScript*

- *InstallScript MSI*

The **Welcome** function displays a dialog that welcomes the end user.

In a procedural script, you must call `SdProductName` before calling `Welcome` so that `InstallShield` can insert the product name into the first paragraph of message text in the `Welcome` dialog. In an event-based script, `SdProductName` is called automatically, with the `PRODUCT_NAME` string entry as its argument, before the `Begin` event. If you do not pass a product name using `SdProductName`, `InstallShield` cannot insert the product name but inserts extra spaces instead.

Syntax

```
Welcome ( szTitle, nReserved );
```

Parameters

Table 42 • Welcome Parameters

| Parameter | Description                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------|
| szTitle   | Specifies the title of this dialog. To display the default title <code>Welcome</code> , pass a null string ("" ) in this parameter. |
| nReserved | Pass 0 in this parameter.                                                                                                           |

Return Values

Table 43 • Welcome Return Values

| Return Value | Description                                                       |
|--------------|-------------------------------------------------------------------|
| NEXT (1)     | Indicates that the end user clicked the NEXT button.              |
| BACK (12)    | Indicates that the end user clicked the BACK button.              |
| < 0          | Indicates that <code>Welcome</code> failed to display the dialog. |

Additional Information

To view an example of this or other dialogs for your installation, use the `Dialog Sampler`. In `InstallShield`, on the `Tools` menu, point to `InstallScript`, then click `Standard Dialog Sampler` or `Skinned Dialog Sampler`.

Welcome Example

**Project** • This information applies to the following project types:

- *InstallScript*
- *InstallScript MSI*

```

/*-----*\
 *
 * InstallShield Example Script
 *
 * Demonstrates the Welcome function.
 *
 * This script displays the installation Welcome dialog.
 *
\*-----*/

#define PRODUCT "ExampleProduct"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

    export prototype ExFn_Welcome(HWND);

function ExFn_Welcome(hMSI)
    STRING svLogFile;
begin

    SdProductName ( PRODUCT );

    // Display the Welcome dialog.
    if (Welcome ("Welcome Dialog Example", 0) < 0) then
        MessageBox ("Welcome dialog failed.", SEVERE);
    endif;

end;

```

## WizardDirection

**Project** ▪ This information applies to InstallScript projects.

The **WizardDirection** function is called in an object script to report the argument that was passed to the most recent call in the main setup's (or parent object's) script to the ShowObjWizardPages function or one of the object's ShowxxxxxUlyyyyy methods.

### Syntax

```
WizardDirection ( );
```

### Parameters

None.

## Return Values

**Table 44** • WizardDirection Return Values

| Return Value | Description                                                                                                                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NEXT</b>  | Indicates that NEXT was passed as the argument in the most recent call in the main setup's (or parent object's) script to the ShowObjWizardPages function or one of the object's ShowxxxxxUlyyyyy methods. |
| <b>BACK</b>  | Indicates that BACK was passed as the argument in the most recent call in the main setup's (or parent object's) script to the ShowObjWizardPages function or one of the object's ShowxxxxxUlyyyyy methods. |

## Additional Information

The purpose of WizardDirection is to report the direction in which the end user was moving through the dialog sequence at the most recent transition to the object's dialog sequence from the main setup's (or parent object's) dialog sequence. For more information, see [Creating the Object's Run-Time User Interface](#).

# WriteArrayProperty

**Project** • This information applies to InstallScript projects.

The **WriteArrayProperty** function is called in an object script to enter a value for a specified property whose value is an array.

## Syntax

```
WriteArrayProperty ( nPropertyBag, szPropertyName, ArrayPointer );
```

## Parameters

**Table 45** ▪ WriteArrayProperty Parameters

| Parameter             | Description                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------|
| <b>nPropertyBag</b>   | Specifies a reference to the object's property bag object, in which property values are stored. |
| <b>szPropertyName</b> | Specifies the name of the property whose value you want to enter.                               |
| <b>ArrayPointer</b>   | Specifies a pointer to the array property.                                                      |

## Return Values

**Table 46** ▪ WriteArrayProperty Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| <b>0</b>     | This function always returns zero (0). |

# WriteBoolProperty

**Project** ▪ This information applies to InstallScript projects.

The **WriteBoolProperty** function is called in an object script to enter a value for a specified property whose value is a Boolean.

## Syntax

```
WriteBoolProperty ( nPropertyBag, szPropertyName, bPropertyValue );
```

## Parameters

**Table 47** ▪ WriteBoolProperty Parameters

| Parameter             | Description                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------|
| <b>nPropertyBag</b>   | Specifies a reference to the object's property bag object, in which property values are stored. |
| <b>szPropertyName</b> | Specifies the name of the property whose value you want to enter.                               |
| <b>bPropertyValue</b> | Specifies the value of the property.                                                            |

## Return Values

**Table 48** ▪ WriteBoolProperty Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| <b>0</b>     | This function always returns zero (0). |

# WriteBytes

The **WriteBytes** function writes a specific number of bytes to a file opened in the binary mode. This function starts writing bytes at the current file pointer location.

**Note** ▪ Before calling *WriteBytes*, you must open the file by calling *OpenFileMode(FILE\_MODE\_BINARY)* and then calling *OpenFile*.

The parameter *nIndex* is an index into *svString*; *nBytes* specifies how many bytes beyond the value of *nIndex* you want to write to the file. If *nIndex* plus *nBytes* exceeds the length of *svString*, *InstallShield* writes only the number of bytes from the index into the string to the end of the string. For example, if *svString* is 100 bytes long, *nIndex* is 50 and *nBytes* is 75, only the bytes between 51 and 100 (50 bytes instead of 75 bytes) are written to the file.

## Syntax

```
WriteBytes (nFile, svString, nIndex, nBytes);
```

## Parameters

**Table 49** • WriteBytes Parameters

| Parameter       | Description                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nFile</b>    | Specifies the file handle of a file that has been opened in binary mode.                                                                               |
| <b>svString</b> | Specifies the string variable that contains the bytes to write to the output file.                                                                     |
| <b>nIndex</b>   | Specifies an index into svString. The bytes starting at this location are written to the output file. Note that the first byte is at index location 0. |
| <b>nBytes</b>   | Specifies the number of bytes you want to write to the output file.                                                                                    |

## Return Values

**Table 50** • WriteBytes Return Values

| Return Value  | Description                                                |
|---------------|------------------------------------------------------------|
| <b>X</b>      | Where X is the number of bytes actually written.           |
| <b>&lt; 0</b> | Indicates that the function was unable to write the bytes. |

## WriteBytes Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the WriteBytes function.
*
* WriteBytes is called to write a company name to a binary file.
*
* Note: Before running this script, set the preprocessor
*       constants so that they reference an existing directory
*       and file on the target system. Because the script will
*       write to this file -- overwriting any existing data --
*       you should create a file or make a copy of an existing
*       file for use with this example.
*
\*-----*/

#define EXAMPLE_DIR "C:\\\"
#define EXAMPLE_FILE "ISExempl.bin"
```

```
// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_WriteBytes(HWND);

function ExFn_WriteBytes(hMSI)
    STRING  szQuestion, svCompany[28];
    NUMBER  nFileHandle, nOffset, nIndex, nBytes;
begin

    // Set the file open mode.
    OpenFileMode (FILE_MODE_BINARY);

    // Open the file and get the file handle.
    if (OpenFile (nFileHandle, EXAMPLE_DIR, EXAMPLE_FILE) < 0) then
        MessageBox ("Unable to open the file.", SEVERE);
        abort;
    endif;

    // Ask user for his or her company name.
    szQuestion = "Please enter your company name. You may enter up to " +
        "twenty-seven characters.";
    AskText (szQuestion, "My Software Company", svCompany);

    // Move the file pointer 15 bytes from the start of the file.
    nOffset = 15;
    SeekBytes (nFileHandle, nOffset, FILE_BIN_START);

    // Write the company name to the file.
    nIndex = 0;
    nBytes = 27;
    if (WriteBytes (nFileHandle, svCompany, nIndex, nBytes) < 0) then
        MessageBox ("WriteBytes failed.", SEVERE);
    else
        MessageBox ("Bytes successfully written to file.", INFORMATION);
    endif;

    // Close the file.
    CloseFile (nFileHandle);

end;
```

## WriteLine

The **WriteLine** function writes a line of text to a text file opened in append mode. You must first set the file mode to append mode with **OpenFileMode**, and then either create the file with **CreateFile**, or open the file with **OpenFile**, before calling **WriteLine**. This function places the line at the end of the file.

**WriteLine** produces lines that have a carriage return and line feed character at the end of the line. To write to a binary file, use **WriteBytes**.

---

**Caution** ▪ This function does not work with files opened in read-only mode.

## Syntax

```
WriteLine ( nvFileHandle, szLine );
```

## Parameters

**Table 51** • WriteLine Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nvFileHandle</b> | Specifies the file handle of an open file. The handle is obtained from <b>OpenFile</b> or <b>CreateFile</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>szLine</b>       | <p>Specifies a string that contains the text to write to the file.</p>  <p><b>Note</b> ▪ You can embed double quotation marks inside a string by delimiting the string with single quotation marks. For example, if you want to write the string "This string contains a double "quotation mark."", you can use the following code:</p> <pre>WriteLine(nvFileHandle, 'This string contains a double "quotation mark."');</pre>  <p><b>Caution</b> ▪ Do not attempt to write multiple lines by embedding newline characters in the string you pass in <b>szLine</b>. The following code writes the string as one line, with an unprintable character between "one" and "This":</p> <pre>szString = "This is line one\nThis is two"; WriteLine(nvFileHandle, szString);</pre> <p>To write two lines with one call to <b>WriteLine</b>, you must embed a return and a newline (in that order):</p> <pre>szString = "This is line one\r\nThis is two";</pre> |

## Return Values

**Table 52** • WriteLine Return Values

| Return Value  | Description                                                           |
|---------------|-----------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully wrote the line to the file.  |
| <b>&lt; 0</b> | Indicates that the function was unable to write the line to the file. |

## WriteLine Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
```

```

* InstallShield Example Script
*
* Demonstrates the CreateFile and WriteLine functions.
*
* Createfile is called to create a file to store a string. The
* string is written into the file by the WriteLine function.
*
* Note: Before running this script, set the preprocessor
*       constant EXAMPLE_DIR so that it references an existing
*       directory on the target system. Note that if the file
*       specified by EXAMPLE_FILE already exists, it will be
*       overwritten.
*
\*-----*/

#define EXAMPLE_DIR "C:\\\"
#define EXAMPLE_FILE "ISExempl.txt"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_WriteLine(HWND);

function ExFn_WriteLine(hMSI)
    STRING  szTitle, szMsg;
    NUMBER  nvFileHandle;
begin

    // Set the file mode to append.
    OpenFileMode (FILE_MODE_APPEND);

    // Create a new file and leave it open.
    if (CreateFile (nvFileHandle, EXAMPLE_DIR, EXAMPLE_FILE) < 0) then
        // Report the error.
        MessageBox ("CreateFile failed.", SEVERE);
        abort;
    else
        // Set the message to write to the file.
        szMsg = "This line was appended by an example InstallShield script.";

        // Append the message to the file.
        if (WriteLine(nvFileHandle, szMsg) < 0) then
            // Report the error.
            MessageBox ("WriteLine failed.", SEVERE);
        else
            // Report success.
            szTitle = "CreateFile & WriteLine";
            szMsg    = "Successfully created and wrote to %s.";
            sprintfBox (INFORMATION, szTitle, szMsg, EXAMPLE_FILE);
        endif;
    endif;

    // Close the file.
    CloseFile (nvFileHandle);

```

```
end;
```

## WriteNumberProperty

**Project** ▪ This information applies to InstallScript projects.

The **WriteNumberProperty** function is called in an object script to enter a value for a specified property whose value is a number.

### Syntax

```
WriteNumberProperty ( nPropertyBag, szPropertyName, nPropertyValue );
```

### Parameters

**Table 53** ▪ WriteNumberProperty Parameters

| Parameter             | Description                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------|
| <b>nPropertyBag</b>   | Specifies a reference to the object's property bag object, in which property values are stored. |
| <b>szPropertyName</b> | Specifies the name of the property whose value you want to enter.                               |
| <b>nPropertyValue</b> | Specifies the value of the property.                                                            |

### Return Values

**Table 54** ▪ WriteNumberProperty Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| <b>0</b>     | This function always returns zero (0). |

## WriteProfInt

**Tip** ▪ All INI file changes should be created in the INI Files view of the IDE. Handling all of your INI file changes in this way allows for a clean uninstallation through the Windows Installer service.

The **WriteProfInt** function modifies an .ini file by inserting or updating a profile string that assigns an integer value to a key. Note the following important points:

- Because of the way in which Windows caches file changes, you should flush the cache buffer after calls to **WriteProfString**.

- Changes made to .ini files can be logged for uninstallation.
- To write a string value to an .ini file, call **WriteProfString** instead.
- Use the **AddProfString** and **ReplaceProfString** functions when you want to modify the System.ini file.

## Syntax

```
WriteProfInt ( szFileName, szSectionName, szKeyName, iValue );
```

## Parameters

**Table 55** • WriteProfInt Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>    | Specifies the name of the .ini file. If the file name is unqualified (that is, if a drive designation and path are <i>not</i> included), InstallShield searches for the file in the Windows folder. If the file does not exist, it is created in the specified folder; if a path is not included in file name, the file is created in the Windows folder. Note that if the file name is qualified with a path that does not exist, WriteProfInt will fail. |
| <b>szSectionName</b> | Specifies the name of the .ini file section in which szKeyName will be inserted or modified. The section name should <i>not</i> be enclosed within delimiting brackets ( [ ] ). The search for this name is <i>not</i> case sensitive.                                                                                                                                                                                                                     |
| <b>szKeyName</b>     | Specifies the unique key to be updated. If a key that is to be updated does not exist in the specified section, it is created.<br><br><br><b>Note</b> • To delete an entire section from an .ini file, pass a null string ("" ) in szKeyName. To delete one or more keys from a section in an .ini file, use <b>WriteProfString</b> .                                     |
| <b>iValue</b>        | Specifies an integer value to assign to the unique key identified by szKeyName.                                                                                                                                                                                                                                                                                                                                                                            |

## Return Values

**Table 56** • WriteProfInt Return Values

| Return Value  | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully updated the specified .ini file. |
| <b>&lt; 0</b> | Indicates that the function was unable to update the specified .ini file. |

## Additional Information

- The WriteProfInt function uses the Windows API WritePrivateProfileString to access the .ini file. Therefore, its functionality is limited by the functionality provided by the Windows API. Consult Microsoft documentation for more information on .ini files.
- Windows 95 and later cache .ini files, which can cause a delay in writing changes to the specified files. This in turn can interfere with subsequent file operations, such as calls to **CopyFile** and **XCopyFile**. Therefore, you

should flush the cache buffer after using WriteProfInt if you are using file operations shortly afterward. Simply call WriteProfInt with null parameters to force Windows 95 or later to write the data to the .ini file immediately, as shown below:

```
WriteProfInt ("c:\\Test.ini", "Windows", "KeyboardDelay", 100);    WriteProfInt ("", "", "", 0); // null
string in first three parameters    //CopyFile should now have access to updated file.    CopyFile
("c:\\test.ini", "d:\\test.ini");
```

## WriteProfInt Example

**Note** ■ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the WriteProfInt function.
*
* This script updates an integer value in an initialization file
* in the Windows directory. If the file does not exist, it is
* created.
*
\*-----*/

// Define the initialization file name.
#define EXAMPLE_INI WINDIR^"ISExampl.ini"

// Define the initialization item and its new value.
#define SECTION "Windows"
#define KEYNAME "OurAppVal"
#define KEYVAL 0

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_WriteProfInt(HWND);

function ExFn_WriteProfInt(hMSI)
begin

    // Update a field in the initialization file.
    if (WriteProfInt (EXAMPLE_INI, SECTION, KEYNAME, KEYVAL) < 0 ) then
        // Report the error.
        sprintfBox (SEVERE, "WriteProfString",
                    "%s could not be updated", EXAMPLE_INI);
    else
        // Report success.
        sprintfBox (INFORMATION, "WriteProfString",
                    "%s was modified.", EXAMPLE_INI);
    endif;

end;
```

# WriteProfString

The **WriteProfString** function writes a profile string to an .ini file. Depending on the values passed to WriteProfString, it can create a section, delete an entire section, create a unique KEY=VALUE entry, delete a KEY=VALUE entry, or update a key's value.

Note the following important points:

- To write an integer value to an .ini file, call WriteProfInt instead.
- Use the AddProfString and ReplaceProfString functions when you want to modify the System.ini file.
- Changes made to .ini files can be logged for uninstallation. However, there are some important restrictions to be aware of. For more information, see Uninstalling Initialization (.ini) File Entries.
- WriteProfString uses the Windows API WritePrivateProfileString to access the .ini file. Therefore, its functionality is limited by the functionality provided by the Windows API. Consult Windows programming documentation for more information on .ini files.
- Windows caches .ini files, which can cause a delay in writing changes to the specified files. This in turn can interfere with subsequent file operations, such as calls to CopyFile and XCopyFile. Therefore, you should flush the cache buffer after using WriteProfString if you are using file operations shortly afterward. Simply call WriteProfString with null parameters to force Windows to write the data to the .ini file immediately:

```
WriteProfString ("C:\\Test.ini", "Windows", "KeyboardDelay", "100");
WriteProfString ("", "", "", ""); // null string for all four parameters
// CopyFile should now have access to updated file. CopyFile ("C:\\Test.ini", "C:\\Temp\\Test.ini");
```

## Syntax

```
WriteProfString ( szFileName, szSectionName, szKeyName, szValue );
```

## Parameters

**Table 57** ▪ WriteProfString Parameters

| Parameter            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szFileName</b>    | Specifies the name of the .ini file. If the file name is unqualified (that is, if a drive designation and path are <i>not</i> included), InstallShield searches for the file in the Windows folder. If the file does not exist, it is created in the specified folder; if a path is not included in file name, the file is created in the Windows folder. Note that if the file name is qualified with a path that does not exist, WriteProfString will fail. |
| <b>szSectionName</b> | Specifies the name of the .ini file section to search for szKeyName. The section name should <i>not</i> be enclosed within delimiting brackets ( [ ] ). The search for this name is <i>not</i> case sensitive.                                                                                                                                                                                                                                                |
| <b>szKeyName</b>     | Specifies the unique key to be updated or deleted. If a key that is to be updated does not exist, it is created. To delete the key specified here, pass a null string ("" ) in szValue. To delete the entire section specified by szSectionName, including all entries within that, pass a null string ("" ) in this parameter.                                                                                                                               |
| <b>szValue</b>       | Specifies the value to assign to the unique key identified by szKeyName. To delete the key, pass a null string ("" ) in this parameter. To delete the value of the key but retain the key itself, pass a blank space in this parameter.                                                                                                                                                                                                                       |

## Return Values

**Table 58** ▪ WriteProfString Return Values

| Return Value  | Description                                                                            |
|---------------|----------------------------------------------------------------------------------------|
| <b>0</b>      | Indicates that the function successfully wrote the string to the specified .ini file.  |
| <b>&lt; 0</b> | Indicates that the function was unable to write the string to the specified .ini file. |

## WriteProfString Example

**Note** ▪ To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```

/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the WriteProfString function.
*
* This script updates a field in an initialization file in the
* Windows directory. If the file does not exist, it is created.
*
\*-----*/

// Define the initialization file name.
#define EXAMPLE_INI WINDIR ^ "ISExempl.ini"

// Define the initialization item and its new value.
#define SECTION "Windows"
#define KEYNAME "Keyboard"
#define KEYVALUE "English"

// Include Ifx.h for built-in InstallScript function prototypes.
#include "Ifx.h"

export prototype ExFn_WriteProfString(HWND);

function ExFn_WriteProfString(hMSI)
begin

    // Update a field in the initialization file.
    if (WriteProfString (EXAMPLE_INI, SECTION, KEYNAME, KEYVALUE) < 0) then
        // Report the error.
        sprintfBox (SEVERE, "WriteProfString",
            "%s could not be updated", EXAMPLE_INI);
    else
        // Report success.
        sprintfBox (INFORMATION, "WriteProfString", "%s was modified.", EXAMPLE_INI);
    endif;

end;

```

## WriteStringProperty

**Project** • This information applies to InstallScript projects.

The **WriteStringProperty** function is called in an object script to enter a value for a specified property whose value is a string.

### Syntax

```
WriteStringProperty ( nPropertyBag, szPropertyName, szPropertyValue );
```

## Parameters

**Table 59** • WriteStringProperty Parameters

| Parameter              | Description                                                                                     |
|------------------------|-------------------------------------------------------------------------------------------------|
| <b>nPropertyBag</b>    | Specifies a reference to the object's property bag object, in which property values are stored. |
| <b>szPropertyName</b>  | Specifies the name of the property whose value you want to enter.                               |
| <b>szPropertyValue</b> | Specifies the value of the property.                                                            |

## Return Values

**Table 60** • WriteStringProperty Return Values

| Return Value | Description                            |
|--------------|----------------------------------------|
| <b>0</b>     | This function always returns zero (0). |

# XCopyFile

The **XCopyFile** function copies one or more files from a source directory to a target directory. The function creates and logs the target directory if necessary. This function can copy subdirectories as well as files. **XCopyFile** creates subdirectories on the target directory if necessary when the constant `INCLUDE_SUBDIR` is passed in the parameter `nOp`.

If you use this function to transfer files to [WINSYSDIR64](#), you must first disable file system redirection using [WOW64FSREDIRECTION](#). Otherwise, files being transferred to WINSYSDIR64 are incorrectly redirected to the 32-bit SysWOW64 folder. Since some Windows functionality that could be used by the installation requires that redirection be enabled to work, Windows documentation recommends that you disable redirection only for as long as necessary. It is recommended that you then enable file system redirection as soon as you have completed transferring the necessary files to WINSYSDIR64. To learn more, see [Targeting 64-Bit Operating Systems with InstallScript Installations](#).

You cannot rename files using **XCopyFile**. To rename a file during a file copy operation, use the **CopyFile** function.

**Tip** • It is strongly recommended that you disable the Cancel button using the **Disable** function before calling the **XCopyFile** function if the status dialog is displayed during the copy. If you do not disable the Cancel button and the end user cancels during the copy file operation, the `OnCancelling` event handler is not called. Instead, the copy file operation returns a failure error code, which your script must handle by calling the appropriate event and then relaunching the copy file operation. You can enable and disable the Cancel button using the [Enable](#) and [Disable](#) functions.

---

**Note** ▪ If you use unqualified file names and set values for `SRCDIR` and `TARGETDIR` when using **XCopyFile**, save the current values using [VarSave](#) before calling **XCopyFile** and then restore them using [VarRestore](#).

## Syntax

```
XCopyFile ( szSrcFile, szTargetPath, nOp );
```

## Parameters

**Table 61** • XCopyFile Parameters

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>szSrcFile</b>    | <p>Specify which files to copy. If the file specified is qualified—that is, if it includes a path—<b>XCopyFile</b> copies the file from the specified location. If szSrcFile contains an unqualified file name—without path information—<b>XCopyFile</b> copies from the folder that is identified by the system variable <b>SRCDIR</b>. To copy multiple files, use wildcard characters in this parameter.</p> <p>You can specify a valid URL in this parameter. If you pass a CGI or ASP request (for example, "http://www.mydomain.net/login.asp?name=Me&amp;pwd=wow"), the response is sent to the file that is specified in the szTargetPath parameter. When passing a URL, do not include wildcard characters. To check the validity of a URL, call the following:</p> <pre>Is (VALID_PATH, szURL);</pre> |
| <b>szTargetPath</b> | <p>Specify the directory to which the files that are specified by szSrcFile should be copied. If this parameter contains a null string (""), the files are copied to the directory that is specified by the system variable TARGETDIR (in InstallScript installations) or INSTALLDIR (in Basic MSI and InstallScript MSI installations).</p> <p>You cannot specify a URL in this parameter. If you do, the function fails and returns ISERR_INVALID_ARG.</p>                                                                                                                                                                                                                                                                                                                                                    |

**Table 61** • XCopyFile Parameters (cont.)

| Parameter  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nOp</b> | <p>Specify the type of copy operation to perform. Pass one of the following predefined constants in this parameter. To specify more than one option, combine constants with the OR ( ) operator.</p> <ul style="list-style-type: none"> <li>● <b>COMP_NORMAL</b>—Copies files to the target system, updating existing same-named files regardless of date, time, or version information.</li> <li>● <b>COMP_UPDATE_SAME</b>—Update the files even if the date, time, or version of the source file is identical to the target file. You must also specify either <b>COMP_UPDATE_DATE</b> or <b>COMP_UPDATE_VERSION</b> with this constant. Otherwise, this constant is ignored.</li> <li>● <b>COMP_UPDATE_DATE</b>—Updates the files based on the file date and time. This constant updates the file if the source file is newer than the target file.</li> <li>● <b>COMP_UPDATE_VERSION</b>—Updates the files based on the file version. This constant updates the file if the source file is newer than the target file. If the file version does not exist in both the source and the target files, date and time are used for comparison. If the file version does not exist for only one file, InstallShield treats the file containing version information as the newer file.</li> <li>● <b>SELFREGISTER</b>—Carries out the self-registration process immediately, when using the "non-batch method" of installing self-registering files.<br/><br/>If you have called <b>Enable</b>(SELFREGISTERBATCH), this option queues up self-registering files for registration. The files are registered once <b>Do</b>(SELFREGISTRATIONPROCESS) is called, when using the "batch method" of installing self-registering files.<br/><br/>Always use SELFREGISTER together with the SHAREDFILE option, combining them with the bitwise OR operator ( ).</li> <li>● <b>SHAREDFILE</b>—Combines shared and locked file handling by causing <b>XCopyFile</b> to treat all files as shared, and to record locked .dll and .exe files for update when Windows or the system restarts. For more information, see <b>RebootDialog</b> and <b>SdFinishReboot</b>.<br/><br/>The SHAREDFILE option causes <b>XCopyFile</b> to treat all files as shared files and increment the registry reference counter by one when the file exists in the target directory and it has a reference count greater than 0. If the shared file does not exist in the target directory and it has no reference counter, the installation creates the counter and sets it to 1. If the shared file already exists in the target directory but has no reference counter, the installation creates the counter and initializes it to 2 as a precaution against accidental removal during uninstallation.</li> </ul> |

**Table 61** • XCopyFile Parameters (cont.)

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <ul style="list-style-type: none"> <li>• <b>LOCKEDFILE</b>—Causes <b>XCopyFile</b> to record locked .dll and .exe files for update when Windows or the system is rebooted. A locked file is a file that is in use by an application or the system when the installation attempts to access or update the file. The LOCKEDFILE option works like SHAREDFILE except that LOCKEDFILE does not create registry entries or modify the registry reference counter. You cannot use the LOCKEDFILE option when using the SHAREDFILE option. There are some unshared files (such as shell extensions) for which the script writer does not want a registry entry and reference counter. These files should never be uninstalled, except by the application itself. LOCKEDFILE allows <b>XCopyFile</b> to handle locked files that are not shared.</li> <li>• <b>EXCLUDE_SUBDIR</b>—Specifies to exclude subdirectories contained in the source path. Note that empty subdirectories are not copied.</li> <li>• <b>INCLUDE_SUBDIR</b>—Specifies that subdirectories below the source path must also be copied.</li> <li>• <b>CLEAR_FILE_ATTR</b>—Specifies to clear the attributes of the copied file. When you use this parameter, the file in the target folder does not have any file attributes set by default. If you do not use this parameter, <b>XCopyFile</b> uses the attributes of the original file for the copied file.</li> </ul> |

## Return Values

**Table 62** • XCopyFile Return Values

| Return Value              | Description                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                         | Indicates that the function successfully copied the files.                                                                                                                                                                         |
| ISERR_INVALID_ARG         | Indicates that an invalid argument was passed to the function.                                                                                                                                                                     |
| All other negative values | <p>Indicates that the function was unable to copy the files.</p> <p>You can obtain the error message text associated with a large negative return value—for example, -2147024891 (0x80070005)—by calling <b>FormatMessage</b>.</p> |

## Additional Information

After you modify .ini files with **WriteProfString**, you must flush the cache buffer before using **XCopyFile**. All .ini files are cached; this behavior can cause a delay in writing changes to the specified files. This in turn can interfere with subsequent file operations. To avoid this problem, simply call **WriteProfString** with null parameters to force Windows to write the data to the .ini file immediately, as show below:

```
WriteProfString ("C:\\Test.ini", "Windows", "KeyboardDelay", "100");
// null string ("" ) for all four parameters
WriteProfString ("", "", "", "");
// XCopyFile should now have access to updated file.
```

```
XCopyFile ("C:\\Test.ini", "C:\\Temp", EXCLUDE_SUBDIR);
```

## XCOPYFile Example

**Note** • To call this function in a Basic MSI setup, you must first create a custom action for the entry-point function, execute the custom action in a sequence or as the result of a dialog's control event, and then build the release.

```
/*-----*\
*
* InstallShield Example Script
*
* Demonstrates the XCopyFile function.
*
* The first call to XCopyFile copies all text files,
* regardless of date, time, or version.
*
* The second call copies program files and creates the
* subdirectories that these files need to be located in.
*
* The third call copies template files based upon the date,
* writing over target files that have the same or earlier date
* as the source files.
*
* The fourth call copies sample files based upon the version
* number, writing over target files that have an older version
* number.
*
* Note: In order for this script to run correctly, you must
*       set the preprocessor constants to a valid file name
*       and path on the target system.
*
\*-----*/
